BIOLOGICAL ABSTRACTS

A COMPREHENSIVE ABSTRACTING *and* INDEXING JOURNAL *of the* WORLD'S LITERATURE *in* THEORETICAL *and* APPLIED BIOLOGY, EXCLUSIVE *of* CLINICAL MEDICINE

UNIVERSITY LIBRARY
Date 1932
ALABAMA

Published (Beginning with the Literature of 1926) Under the Auspices of the

UNION OF AMERICAN BIOLOGICAL SOCIETIES

With the Cooperation of Biologists Generally

CONTENTS FOR JANUARY 1932

General Biology	*
Biography, History and Bibliography	1- 14
Evolution	14- 24
Cytology	25- 31
Genetics	*
Biometry	*
Ecology	32- 66
Phytopathology	67- 133
Plant Physiology, Biochemistry, and Biophysics	*
Animal Physiology, Biochemistry, and Biophysics	
General	134- 152
Colloids, Permeability, Osmosis, etc.	153- 180
Enzymes and Catalysts	181- 209
Electrolytes and Ions	210- 269
Light and Heat	270- 294
Electricity, X-Ray, Radium	295- 322
Oxidation and Reduction.	*
Methods and Apparatus.	323- 394
Blood and Body Fluids.	*
Nutrition, Diet, Vitamines, General Metabolism, Growth	395- 660
Digestive System and Secretions	661- 711
Respiration	712- 723
Endocrinology	724- 883
Kidney, Urine, External Secretions	*
Reproduction and Lactation	884- 962
Reactions of the Organism as a Whole	963- 977
Sense Organs	978- 998
Nervous System	999-1032
Motor Apparatus	1033-1093
Vascular System	1094-1141
Pharmacology	1142-1259
Animal Pathology	
General	*
Morbid Anatomy	*
Functional	1260-1313
Lower Animals	1314-1371
Immunology	
Bacterial and General	1372-1655
Parasitological	1656-1664
Parasitology (Animal)	1665-1742
Filterable Viruses (Animal), Bacteriophage, etc.	1743-1783
Bacteriology and Other Microbiology	
Medical	1784-1793
Public Health	1794-1803
Food and Industrial	1804-1815
Dairy	1816-1826
Soil	1827-1831
Bacteriology (General)	1832-1841
Economic Entomology	
General	P. 196
Fruits	1842-1852
Cereal, Forage, and other Field Crops	*
Truck and Greenhouse Crops	1853-1865
Stored Products	1866-1873
Forest and Shade Trees.	1874-1878
Insects Affecting Animals	1879-1887
Inspection and Regulation	*
Biological Control	*
Insecticides and Apparatus	1888-1899
Apiculture	1900-1907
Sericulture	*
Economic Ornithology	*
Animal Production	1908-1926
Agronomy	*
Horticulture	1927-1936
Forestry	1937-1961
Pharmacognosy and Pharmaceutical Botany	*
Systematic Botany	
Algae	1962-1994
Fungi	1995-2029
Bryophyta	2030-2042
Pteridophyta	2043-2052
Spermatophyta	2053-2116
Morphology and Anatomy of Vascular Plants	2117-2152
Paleobotany	2153-2175
Paleozoology (General)	2176-2195
Vertebrate Anatomy, Histology and Physical Anthropology	2196-2310
Embryology (Animal)	
Vertebrate	2311-2340
Invertebrate	*
Systematic Zoology	
Protozoa	2341-2355
Porifera	2356-2366
Coelenterata and Ctenophora	*
Platyhelminthes and Mesozoa	2367-2375
Nemathelminthes and Nematomorpha	2376-2389
Acanthocephala	*
Sipunculoidea	*
Nemertea	*
Rotatoria, Gastrotricha, and Chaetognatha	2391-2395
Annelida	2396-2410
Brachiopoda, Bryozoa, Phoronidea	2411-2415
Echinodermata	*
Mollusca	2416-2486
Myriopoda, Onychophora.	*
Crustacea	2487-2510
Entomology (General)	P. 280
Acarina	*
Arachnida (except Acarina)	*
Coleoptera	2511-2564
Diptera	2565-2598
Hemiptera and Homoptera	2599-2606
Hymenoptera	2607-2669
Macrolepidoptera	2670-2704
Microlepidoptera	2705-2716
Neuropteroids	2717-2728
Orthopteroidea	2729-2740
Smaller Orders of Insecta	2741-2756
Fossil Insecta	2757-2759
Prochordata	*
Cyclostomata, Elasmobranchii, Pisces	2760-2800
Amphibia, Reptilia	2801-2815
Aves	2816-2916
Mammalia	2917-3000

Publication Office: 1500 Greenmount Ave., Baltimore, Md.
Editorial and Executive Office: University of Pennsylvania, Philadelphia, Pennsylvania, U. S. A.

Entered as second-class matter Dec. 23, 1926, at the Post Office at Menasha, Wisconsin, under Act of Aug. 24, 1912.
Application has been made to transfer to Baltimore, Maryland.
Published six times a year.

FOR EDITORIAL AND SUBSCRIPTION NOTICES, SEE THIRD COVER PAGE

Explanatory

Typography for Taxonomy.—A special typography has been adopted for new species and other new taxonomic units in both the abstracts and the indexes. This has been done in large part to facilitate reference work; in part, however, it has been done to conserve space by making it unnecessary in the majority of cases to employ the oft-recurring "n. sp.," "n. var.," "n. gen.," or other explanatory abbreviations or phrases. Briefly, the procedure is as follows:

For *new species,* varieties, etc., the specific varietal, etc., name of the binomial, trinomial, etc., is printed in bold-faced type; *e.g., Euglena* **reticulata**; *Keratella serrulata* var. **curvicornis.** (NOTE: In the event a new species, variety, etc., is illustrated, an asterisk (*) is affixed to the specific, varietal, etc., name.)

New generic names appear in all bold-faced capital letters and usually without designation of rank; *e.g.,* **CARIDINIDES.** Other new super-specific group names likewise are printed in all bold-faced capital letters, but to prevent confusion (especially between subgeneric and generic names), these are accompanied by a statement of the rank assigned by authors to the new groups.

Where *new names* and *new combinations* are included in the abstracts and indexes the specific name usually appears in bold-faced type followed by the old combination in parentheses and in italic type; *e.g., Diadasia* **chilensis** (*Anthophora chilensis* Spinola). This procedure is used in response to a demand to give such changes typographic prominence. When for any reason the synonym cannot be given, appropriate explanatory abbreviations (n. n., n. comb., etc.) are employed, thus preventing any possible confusion with new species.

New synonyms are preceded by an equality sign and placed in parentheses; the name under which the synonym is sunk precedes. *E.g., Coreopsis delphinifolia* Lam. (= *C. discolor* Link).

AMERICAN JOURNAL OF BOTANY

Devoted to All Branches of Botanical Science

Established 1914. Monthly, except August and September. Official Publication of the Botanical Society of America.

Subscription, $7 a year for complete volumes (January to December). Parts of volumes at the single number rate. Volumes 1-18 complete (as available), $146. Single numbers, $1.00 each, post free. Prices of odd volumes on request. Foreign postage: 40 cents.

ECOLOGY

Devoted to All Forms of Life in Relation to Environment

Established 1920. Quarterly. Official Publication of the Ecological Society of America. Subscription, $4 a year for complete volumes (January to December). Parts of volumes at the single number rate. Back volumes, as available, $5 each.

Single number, $1.25, post free. Foreign postage: 20 cents.

GENETICS

A Periodical Record of Investigations Bearing on Heredity and Variation

Established 1916. Bimonthly.

Subscription, $6 a year for complete volumes (January to December). Parts of volumes at the single number rate. Single numbers, $1.25, post free. Back volumes, as available, $7.00 each. Foreign postage: 50 cents.

BROOKLYN BOTANIC GARDEN MEMOIRS

Volume I: 33 contributions by various authors on genetics, pathology, mycology, physiology, ecology, plant geography, and systematic botany. Price $3.50, plus postage.

Volume II: The vegetation of Long Island. Part I. The vegetation of Montauk, etc. By Norman Taylor. Pub. 1923. 108 pp. Price $1.00.

Volume III: The vegetation of Mt. Desert Island, Maine, and its environment. By Barrington Moore and Norman Taylor. 151 pages, 27 text figures, vegetation map in colors. June 10, 1927. Price, $1.60. ***Orders should be placed with***

VOLUME 6 — JANUARY, 1932 — Entries 1-3000 — NUMBER 1

BIOGRAPHY, HISTORY, AND BIBLIOGRAPHY

CARROLL W. DODGE, *Editor*

See also in this issue Entries 16, 23, 151, 1473, 1670, 1794, 1802, 1938, 2102, 2112, 2195, 2245, 2562, 2767)

1. **BARBOSA SUEIRO, M. B. Notas históricas sôbre a vivissecção humana.** *Arquivo Anat. e Antrop.* 13(1/2): 273-285. 1929 (1930).—Referring to the antipathy to vivisection felt by many people including Shakespeare, Richard Wagner, Mark Twain and Bernard Shaw, the author points out the important part which this method played in the discovery of the circulation of the blood by Harvey. Tradition includes Herophilus and Erasistratus among those who practised human vivisection. In the Middle Ages the influence of Catholicism and the scientific dictation of Galen hampered the progress of anatomy. The history of anatomical reform from Mondinus to Vesalius is discussed, mentioning Berengario da Carpi among those alleged to have dissected living human beings. This is regarded as unproven, although the difficulties of dissection may have tempted anatomists into culpable practices. In this connection the author recalls the gruesome collection of cadavers by Fallopius, Sylvius, Fault, Boyer and others. He does not accept the view of St. Paul that it is proper to make physiological experiments on living criminals, mentioning in this connection the popular legends and the celebrated reply of Genettes to Bonaparte. He discusses also the history of voluntary vivisection, including the cases described by Hector Chaussier and those of Vesalius and Las-.—*M. B. Barbosa Sueiro* (*transl. by G. W. Corner*).

2. **BUDDENBROCK, W. von. Bilder aus der Geschichte der biologischen Grundprobleme.** 158p. 8 portraits. Gebrüder Borntraeger: Berlin, 1930. Pr. 5S M.—The history of biology is here treated in 4 main divisions as follows: origin of life (spontaneous generation, fertilization problem, embryogenesis); organization of life (cell doctrine, problem of organic fitness); position of organisms in nature (the energy principle and life, chemistry and life); and the maintenance of life and organic evolution (heredity, origin of species). Portraits of O. Hertwig, v. Baer, Roux, Buetschli, Weismann, Mendel, C. Darwin, and Haeckel are included.—*A. M. Chickering.*

3. **CHITTENDEN, RUSSELL H. The development of physiological chemistry in the United States.** (American Chemical Soc. Monograph Ser. No. 54) 427p. Chemical Catalog Co., Inc.: New York, 1930. Pr. $6.00.—"The attempt has been made to show by explicit statements of actual experimental accomplishments, at different times and in different places, by many workers and groups of workers, something of the progress which has been made in this country during the past half century in the field of Physiological Chemistry." The book is "an exposition of the growth and development of Physiological Chemistry in this country" and no attempt is made at a critical analysis of the accomplishments recorded. The earlier chapters, dealing with Physiological Chemistry at the time when Chittenden himself was an outstanding figure, are essentially autobiographical. The later chapters take the development of special lines of study and give a [illegible] most of the investi-

[illegible] lava field (malpais) was still too warm [illegible] vegetation. In 1827 Burkart reported [illegible] over the "malpais," and in 1846 210p. Portrait. 21 fig. Oxford Univ. Press: New York, 1930. Pr. $6.00.—This book is a history of the controverted theories of preformation and epigenesis. The author calls this extensive "essay" an attempt to give "the complete story of the Preformation Doctrine." The book is divided into 8 chapters—2 on the history of our knowledge of spermatozoa, 3 on the rise, development, and fall of the preformation doctrine, 1 on epigenesis, 1 covering early theories of fertilization and development, and 1 in retrospect of the entire field. Thus the author has traced not only the theories of preformation but those on epigenesis as far as the modern physiological idea of predeterminism. The material has been gleaned from the known works and published writings from 1600 on, with especial attention to Leeuwenhoek, and with nearly 300 original papers listed in the literature consulted. The illustrations, which have not been reproduced before, are from the original (now classic) speculative writings. By illuminating our sometimes "fatal preoccupation with philosophy," the book demonstrates "one conclusion before all others," that the most difficult of all human tasks is to "observe natural phenomena faithfully" and without surmises and inventions. The book fills an old need by covering thoroughly these fundamental biological philosophies, and incidentally it settles many questions of priority decisively by direct reference to original sources.—*F. W. Appel.*

5. **CONN, H. J. The history of staining.** *Stain Tech.* 5(1): 3-12. 1930.—This is the 4th paper of a series on the history of staining, deals with the introduction of anilin dyes into histology, and the important procedures employing these dyes proposed during the last 4 decades of the 19th century.—*Author* (*courtesy Wistar Bibl. Serv.*)

6. **DRACHMAN, JULIAN M. Studies in the literature of natural science.** 487p. 3 portraits, 1 pl. Macmillan Co.: New York, 1930. Pr. $4.00.—This is said to be the first book criticizing scientific writings as literature. The author limits himself to 19th century English works on natural science, though he touches outside these limits where so doing is illuminating. The book is divided into 4 parts; the first 3, chiefly concerned with the evolutionary theory, constitute a history of its development, giving the effects and tracing the gestation of various contributory ideas. Charles Darwin's works occupy chief place, but those of Hutton, Lyell, Murchison, Linnaeus, Buffon, Erasmus Darwin, Lamarck, Cuvier, Hugh Miller, Spencer, Wallace, Huxley, and others are discussed. The last part is a study of less cataclysmic writings. Taking the writer's aim as the basis for classification the following groups are discussed: the great synthesists, the popularizers of science, essayists and journalists, and astronomists who raised the question of life on other planets. The discussions are not as closely confined to men of the 19th century. Some of those named are Aristotle, Bacon, Comte, Drummond, Fiske, Faraday, Tyndall, the Gosse brothers, Agassiz, Izaak Walton, W. H. Hudson, W[illegible] and Brewster.—*attachments.*

London B 218(454): 171-182. 1 pl. 1930.—Attention is directed to the close correlation between "factors" in environment and "characters" of population. "Fac-

stock [1854-1930]. *Ent. News* 41(8): 227-279. 1930.—An account of the life and work of this American naturalist, emeritus professor of nature study at Cornell University, wood engraver and author.

8. **GREGORY, WILLIAM K. Memorial of Bashford Dean. Article 1 of: The Bashford Dean Memorial Volume: Archaic fishes. Edited by EUGENE WILLIS GUDGER.** 42p. Portraits. American Museum of Natural History: New York, 1930.—An account of Dean's life and works, showing the development of his 2 lifelong interests,—fossil and recent ichthyology, and arms and armor. He was curator of the latter in the Metropolitan Mus. of Art. As founder, curator and later honorary curator of the Department of Ichthyology in the Amer. Mus. Nat. Hist., he continued the work of J. S. Newberry on Devonian fishes, his studies culminating in a far reaching contribution to the problem and evolution of the paired appendages of vertebrates; the Devonian shark *Cladoselache newberryi* bringing weighty evidence in support of the Thacher-Balfour fin-fold theory of the origin of the paired fins. His studies of the archaic survivors of the sharks and ganoids resulted in the accumulation of a great series of beautifully executed plates of the development of these forms, many of which, unpublished at the time of his death, will appear in forthcoming parts of the Dean Memorial Volume. The department of Ichthyology in the American Museum is still keeping up, as a card catalogue, Dean's great Bibliography of Fishes, the 3 published volumes of which contain some 20,000 references to scientific books and papers dealing with fish life. Together with his text book, Fishes Living and Fossil, this work exemplifies Dean's high ideal of service to students and to other scientists.—*G. LaMonte.*

9. **HOFFMANN, ADOLF. Entomologen-Adressbuch.** [Address book of entomologists.] 3rd ed. 400p. Adolf Hoffmann: Wien, 1930. Pr. $3.

10. **HOWARD, L. O. The rise of applied entomology in the United States.** *Agric. History* 3(3): 131-139. 1929.—At the 12th annual meeting of the Agricultural History Soc., in Washington, 1929, this brief history of economic entomology in this country was given. An extraordinary increase in public appreciation has occurred, especially during the past 30 yrs. Some account is given of early workers, and some generalizations are made as to recent occurrences and the present outlook.—*L. O. Howard.*

11. **MacCALLAN, A. F. Mediaeval ophthalmology in Mesopotamia.** *Brit. Jour. Ophthalmol.* 14(10): 596-610. 1930.—Account of a treatise, the earliest existing systematic text-book of ophthalmology, by Abu Zaid Hunain ibn Is-Haq el Ibadi [809-877].

12. **MAJOR, RALPH H. The history of taking the blood pressure.** *Ann. Med. Hist.* 2(1): 47-55. 14 fig. 1930.—Stephen Hales recorded his first observations on blood pressure in 1733. These were reports of experiments performed in 1708 on the crural arteries of dogs. About 6 yrs. later he took the blood pressure of 2 horses and a fallow doe. He also measured the pressure of rising sap in trees. Jean-Léonard-Marie Poiseuille in 1828 described a hemodynameter which was an improvement over the apparatus used by Hales for measuring blood pressure. Carl Ludwig in 1847 measured blood pressure and recorded it on a kymograph. The first accurate determination of human blood pressure was made by Faivre in 1856. Karl Vierordt in 1855 introduced the method of indirect measurement of blood pressure by measuring the counterpressure necessary to obliterate the pulsation in the artery; his apparatus is the direct ancestor of the present day sphygmograph. Marey somewhat later invented a sphygmomanometer which was clumsy but moderately accurate. Von Basch, in 1880, invented the first accurate and practical sphygmomanometer. In 1896 Riva-Ricci made a sphygmomanometer quite similar to the one in present use.—*N. M. Boyd.*

13. **MELLISH-WILSON, MAUD H. The writing of medical papers.** [3rd ed.] 184p. W. B. Saunders Co.: Philadelphia, 1929. Pr. $1.50.

14. **SHAW, DAPHNE. (Compiled by.) A catalogue of British scientific and technical books.** 3rd ed. 734p. Sold by A. & F. Denny, 163A Strand, W. C. for the British Science Guild, 6 John St., Adelphi, W. C. 2, London, 1930. Pr. 20s.

EVOLUTION

(See also in this issue Entries 45, 1052, 2215, 2293, 2630, 2807, 2926, 2962, 2968, 2980)

15. **COSTANTIN, J. Une importante application du Lamarckisme à l'agriculture tropicale. (Examen critique du Lamarckisme.)** *Arch. Mus. Hist. Nat.* [*Paris*] 6: 63-73. 1930.—It has been demonstrated by nearly 50 yrs. of agriculture that mountain climate gives plants resistance. This principle has been used economically with sugar cane in Java. The practice of using cuttings from high altitudes is an application of Lamarckian factors. It has been used in America in dealing with the mosaic disease of sugar cane, and it has been of service in connection with the potato, with *Hevea brasiliensis*, and with coffee. The rôle of Lamarckian factors in plant evolution is regarded as established, regardless of other factors concerned. It makes possible an explanation in genetic terms of changes of sex brought about by environment. The theory is closely connected with the work done in America on the effects of radium and x-rays on the germ plasm.—*From abst. by J. Costantin (transl. by P. Weatherwax).*

16. **DUDYCHA, GEORGE J. LeConte's Epitome of Evolution.** *Ohio Jour. Sci.* 31(2): 107-114. 1931.—LeConte in his "Evolution" (1887) says: "Evolution is (1) continuous progressive change, (2) according to certain laws, (3) and by means of resident forces." By "progressive change," he apparently means improvement in adaptation to environment accompanied by an increase in complexity. Of LeConte's 3 laws—differentiation, progress of the whole, and cyclical movement—only the [illegible] as he himself admits, is of any significance. The [illegible] forces of which he speaks are, God, Divine Will [illegible]. Thus after a [illegible] interprets [illegible] in the direction of greater complexity [illegible] differentiation due to a Vital Force. This is not new, for Heraclitus pointed out the significance of change; the idea of complexity we find in Lamarck, Darwin and the Neo-Darwinians; differentiation was emphasized by Spencer, and Vital Force or God is a concept which [illegible] in the history of evolutionary thought as a [illegible]. Thus LeConte's contribution rests in the fact that he epitomized the major ideas concerning evolution which were presented by thinkers before the 20th century. LeConte significantly marks the close of a long period in the history of evolutionary thought.—*G. J. Dudycha.*

17. **GRUENBERG, BENJAMIN C. The story of evolution. Facts and theories on the development of life.** 473p. D. Van Nostrand Co., Inc.: New York, 1930. Pr. $4.00.

18. **[illegible]NSTONE, JAS. Emergent evolution.** *Nature* [*London*] 127(3193): 55. 1931.—The concept of "emergence" by which primary units (e.g., atoms of O and H), combined into units of a higher order (e.g., molecules of water), display new, "emergent" properties (e.g., "liquidity") not revealed by them prior to their occurrence in that particular configuration, is criticized. The author asks for a dispassionate analysis of such concepts as "emergence."

19. **JOLLOS, VICTOR. Gerichtete Mutationen und ihre Bedeutung für das Evolutionsproblem. Erwiderung auf L. Plates "Bemerkungen zu den Jollos' schen Orthomutationen von Drosophila."** *Biol. Zentralbl.* 51(3): 137-140. 1931.

ECOLOGY

W. C. ALLEE, *Editor*, Animal

GENERAL

32. **BRUNKER, J. P., and A. W. STELFOX, with an introduction by C. B. MOFFAT. Phenological report for 1930.** *Irish Nat. Jour.* 3(7): 138-146; (8): 171-175, 1931.—Data are compiled from many sources on flowering time of wild and garden plants; leafing of trees and arrival of birds in spring; the song first heard after winter silence; the time for cutting of crops; time of appearance of plant diseases, of frogspawn and of ripening of wild raspberries; insects first seen; and the time of departure of summer migrants and arrival of winter migrants.

33. **COLEMAN, EDITH. Pollination of some West Australian orchids.** *Victorian Nat.* 46(10): 203-206. 1930.—The belief that the ichneumon fly, *Lissopimpla semipunctata*, is responsible for the pollination of *Cryptostylis ovata* R. Br. is confirmed by the observations of B. T. Goodby in West Australia. Observations on *Caladenia barbarossae* in the same State indicate that a small bee or fly is concerned in its pollination. Are the ♂ insects attracted to the flowers by scent or by fancied resemblance to ♀♀ of their kind? In flowers of *Diuris pedunculata* are frequently found Halictus bees, *Halfiops lanarius*, which appear to be stupefied.

34. **GADOW, HANS (with an editorial note by PHILIP LAKE and a prefatory note by A. C. SEWARD). Jorullo. The history of the volcano of Jorullo and the reclamation of the devastated district by animals and plants.** 100p. Map. Portrait. 2 fig. Cambridge Univ. Press: London, 1930. Pr. 7s. 6d.—Jorullo stands in an amphitheatre among the foothills of the great southern slope of the Mexican plateau. In 1759 a series of volcanic eruptions occurred which completely destroyed all vegetation over an area of 26 sq. miles and covered thickly with volcanic ash a much larger area. Five volcanic cones were developed, the largest being some 820 ft. high with a circular crater. These cones were breached on their southwest sides and from them poured masses of lava in 4 or 5 distinct flows, covering 3.5 sq. miles with molten rock. Humboldt in 1803 found an ash covered plain (playa) well covered with masses of *Salvia*, *Corypha pumos*, and *Alnus jorullensis*, but the lava field (malpais) was still too warm to support any vegetation. In 1827 Burkart reported vegetation advancing over the "malpais," and in 1846 Schleiden reported much of the "malpais" still bare but the remainder with low mimosa and quava trees. In 1886 Leclerg found the vegetation on the "malpais" quite luxuriant with the quava scrub confined to an area near the crater; thus the vegetation had reclaimed the lost ground within 90 yrs. in a region with about 68 cm. of annual rainfall. Gadow reports the increase in size of trees and of the luxuriance of the flora after the lapse of a half century. All except the "malpais" is under cultivation. Notes are given on the development of *Copernicus pumos*, and of sp. of *Loranthus*, *Ficus*, and *Opuntia*. In the devastated plain of the Jorullo 33 sp. of Reptilia and Amphibia were found, only 6 on the center of the "malpais" and only 2 on top of the volcano. An annotated list of these animals is given with a general discussion of the Amphibia and Reptilia of the surrounding province of Michoacan.—*G. D. Fuller.*

35. **RAUP, H. M. The pollenization of Habenaria obtusata.** *Rhodora* 32(376): 88-89. 1 fig. 1930.—Pollination is due to mosquitoes, which carry pollinia.—*S. F. Blake.*

36. **STEINECKE, FR. Die Nekrozönosen des Zehlaubruches. Studie über die Entwicklung des Hochmoors an Hand der fossilen Mikroorganismen.** *Schriften Phys.-Ökon. Ges. Königsberg i. Pr.* 66(1): 193-214. 1929.—Analyses of the micro-fossils, consisting of 20 algae, 30 rhizopods, and some rotifers and arthropods from borings of this the largest high moor of north Germany, are compared with recent biocenoses. On this basis, the high moor in question is believed to have arisen in Atlantic time by the submersion of a mixed forest.—*F. Steinecke (transl.).*

37. **ANONYMOUS. The relation of the fauna and flora of the British Isles to those of North America.** *Nature [London]* 127(3204): 501-502. 1931.—Report of a discussion.

ANIMAL

38. **HORA, SUNDER LAL. Ecology, bionomics and evolution of the torrential fauna, with special reference to the organs of attachment.** *Phil. Trans. Roy. Soc. London B* 218(454): 171-182. 4 pl., 22 fig. 1930.—Attention is directed to the close correlation between "factors" in environment and "characters" of population. "Fac-

" are treated under (1) the physical conditions (rate low of current, the high % of O in the water, shalness and low temp.) that influence the ecological ribution of the torrential fauna and (2) the biological ors such as food and protection from enemies. Habiin a torrent are classified and discussed. In studying bionomics of the torrential fauna attention has been nly directed to the insects and the vertebrates. ong insects the torrent-inhabiting forms are dised with special reference to their organs of attachıt which are specially modified to withstand the ning currents. In fishes attachment to the substratum ffected either by the formation of a sucker or more n by means of a reduction of the pressure on the tral aspect by various devices. Evolutionary series w gradual modifications induced by environmental ors. The brook-inhabiting tadpoles are classified into ological associations, and their chief characteristics are ussed. The probable mode of evolution of the funnelped mouth of the *Megalophrys* tadpoles is indicated. lealing with the physics of the mechanism of attachıt, it is indicated that the resistance has been diished by a reduction in size, by assuming streamforms, by smoothing of the surface at a certain ocity, and by roughening the surface at a different ocity. The mechanical devices for fixation are sticky etions, vacuum-producing devices, "seizing" devices, hooking devices. Numerous instances of parallel lution are cited, and it is suggested that community habitat has led to structural convergence. Congence implies resemblances "which result from indeident functional adaptation to similar ends." Attenı is also directed to "divergent" evolution (Annane) and to the causes that produce it. It has been posed by certain workers (e.g., Hubault) that the rential fauna is of glacial origin, but evidence shows t this fauna has colonized the torrents by means of tep-by-step migration from lower levels. The causes this migration are studied and the part played by nge of function is indicated with the help of several mples. No attempt has been made to study the ses of variations or the mode of their transmission, t an effort has been made to show, from a purely logical point of view, how animals become adapted their surroundings.—*S. L. Hora.*

PLANT

39. **ANDERSEN, SVEND. Danske Vegetationslleder. [The vegetation of Denmark.]** *Flora og Fauna openhagen]* 1929(3): 73-77. 1929.—Descriptions of the untry around the bay of Sejrö, Denmark, and a list of aracteristic sp.

40. **BØRGESEN, F. Fra en Rejse i Indien 1927-28. rom a journey in India.] (With English Abstract.)** *t. Tidsskr. [Copenhagen]* 41(2): 113-153. 14 fig. 1930.—r Dwarka and Tuticorin are given local floras and ological spectra of growth-forms, accompanied by hyotherm-curves. The strand flora of Tuticorin is comred with other sand-floras whose spectra are also ven.—*Ove Paulsen.*

41. **FULLER, MARY. An excursion to Barrington ops, August, 1928.** *Australian Nat.* 7(8): 156-163. 2 fig. 29.—The little-known plateau of Barrington Tops, evation 4000-5000 ft., is an isolated spur of the Great ividing Range, composed of granitic rock, with baltic intrusions, much dissected by streams, and occued by numerous swamps. The climate, reflected in the ora, is subalpine, with the snow-grass, *Poa caespitosa,* e most characteristic feature. The pink tinge of the oors in summer is due to *Stylidium graminifolium.* round orchids are extremely abundant. The hillocks, vered by open *Eucalyptus* forest, have only a scanty idergrowth of *Acacia* and *Hakea,* but in sheltered rges is a luxuriant vegetation, with *Aspidium aculeam* replacing the snow-grass; and on the treeless tracts eat patches of *Juncus, Gahnia,* and *Sphagnum* are minant. The *Fagus* forest and abundant *Dicksonia antctica* are Tasmanian elements, reflecting the similarity of the 2 climates. The snow-grass comes no lower than 3000 ft., and is replaced on the flats by *Xerotes* and xerophitic shrubs; a rain-forest jungle of tall eucalypts and *Syncarpia* sp. with the abundant lianas fills the Allyn Valley. Many of the conspicuous ferns, orchids, etc., are enumerated. The abundant lichen flora of the summit included the Tasmanian *Nephroma antarctica* and *N. cellulosum,* not hitherto recorded from New So. Wales.—*H. K. Svenson.*

42. **GATES, F. C. Heat and the flowering of Utricularia resupinata.** *Ecology* 10(3): 353-354. 1929.—A combination of low water level and high temp. are the necessary conditions for this plant to flower. *U. resupinata* has flowered but twice since 1915 in the Douglas Lake (Michigan, U. S. A.) region.

43. **GOOD, R. D'O. Plant distribution.** *Nature [London]* 127(3204): 484. 1931.—This preliminary note states the thesis that each sp. has, as one of its specific characters, a "range of tolerance" to external conditions,—a character subject to variation and change just as morphological characters are. An external change, being a "movement of conditions," "must result in sp. movement because dispersal, which is potentially in all directions, will be effective only in those directions which will maintain the spatial correlation between the sp. and the conditions within its range of tolerance."

44. **GYÖRFFY, ISTVÁN. Phytophaenologia Szegediensis anni 1929. Szeged 1929. évi növényphaenologiâja. VII. közlemény.** *Acta Litt. ac Scient. R. Univ. Hung. Francisco-Josephinae. Sect. A.* 1(3): 296-299. 1930.—Consists chiefly of a phenological table of 92 spp. of plants.

45. **HAYATA, BUNZO. Succession in the vegetation of Mt. Fuji and the formulation of a new theory, the succession theory, in opposition to the natural selection theory.** *Proc. 3rd Pan-Pacific Sci. Congress, Tokyo* 2: 1867-1868. 1926(1928).—Successional changes in forests on Mt. Fuji are described briefly. Some formations, as those dominated by white fir (*Abies veitchii*), are short lived, and seem to die a "natural" death. It is concluded that natural selection has nothing to do with plant succession; that plant succession, and the extinction of sp. in evolution, are controlled by an "innermost factor, which acts like a man holding the leading-strings of dancing puppets, from back of the scene where nothing but physiographical or biotic factors seem to act their parts in the play."

46. **HU, H. H. A preliminary survey of the forest flora of southeastern China.** *Proc. 3rd Pan-Pacific Sci. Congress. Tokyo* 2: 1904-1905. 1926(1928).—Abstract.

47. **JAHN, REINHOLD. Pollenanalytische Untersuchungen an Hochmooren des Thüringer Waldes.** *Forstwiss. Centralbl.* 52(19): 761-774; (20): 810-818. 6 fig. 1930.—Pollen counts at various depths in several peat profiles showed spruce and hazel predominating in the lowest layers (155-350 cm. deep), followed by a rapid increase of beech. Toward the surface the beech pollen is less abundant and spruce and pine again predominate. Oak and linden pollen is more abundant at the lower levels than above. Pollen grains of *Abies, Picea, Pinus, Fagus, Alnus, Betula, Quercus, Tilia, Ulmus, Carpinus, Salix,* and *Corylus* were found in all samples, but not at all levels in each sample. The pollen studies indicate that the moors originated in the Atlantic period, probably around 4000 B. C. As in other German moors, there is a maximum of birch and hazel pollen at depths of 100-50 cm., coinciding with a more complete decomposition of the peat moss. This indicates an opening up of the stand following human settlement in the vicinity. The transition from beech to the spruce type now predominating may be due partly to climatic change, but principally to the influence of forestry measures.—*W. N. Sparhawk.*

48. **KORIBA, KWAN, and ZENTARO TASHIRO. On the vegetation of Sakurajima after the eruption of 1914.** *Proc. 3rd Pan-Pacific Sci. Congress, Tokyo* 2: 1898-1899. 1926(1928).—Abstract.

49. **LAWSON, A. ANSTRUTHER. The origin of endemism in the angiosperm flora of Australia.** *Proc.*

Linn. Soc. N. S. Wales 55(4): 371-380. 2 pl. 1930.—The Australian flora is characterized by the number, abundance, and predominance of *Eucalyptus* sp.; by the striking and varied xerophily of the flora, widely diverse families (Myrtaceae, Leguminosae, Proteaceae, Compositae, Orchidaceae, Epacridaceae, Rutaceae, Casuarineae, et al.) having undergone modifications, often convergent, such as reduced leaf surface, heavy cutinization, etc.; and by the presence of many endemic types, especially in the Myrtaceae, Leguminosae, Proteaceae, Orchidaceae, Epacridaceae, Rutaceae, Goodeniaceae, Casuarineae, et al. Some 70% of the sp. and 30% of the genera are endemic; in Western Australia, 85% of the sp. Studies of microsporogenesis and pollen viability in Proteaceae and Myrtaceae show a high % with abortive seed, sterile pollen, abortive pollen grains, and species sterility. It is concluded that the majority, if not all, of the endemic sp. of these 2 families are of hybrid origin.

50. **McDOUGALL, W. B. Plant Ecology.** 2nd ed. 338p. 120 engravings. Lea & Febiger: Philadelphia, 1931. Pr. $4.00.

51. **MARKUS, E. Die Grenzverschiebung des Waldes und des Moores in Alatskivi.** *Acta et Comment. Univ. Tartuensis (Dorpatensis) A. Math. Phys. Med.* 19(3): 1-157. 10 fig. 1929.—The changing limits of 2 bio-communities constitute a succession. The shifting boundaries between forests and bogs at Alatskivi, in Esthonia, near Tartu, are discussed. A community (Naturkomplexe) is a complex of phenomena and objects connected causally and existing on a certain portion of the earth's surface. In each community, quadrats of 100 sq. m. are taken and the plants are listed according to layers, with degree of covering (according to the Swedish method) and a detailed description of the soil conditions. Many (26) communities and so-called resting communities are described. The shifting of the boundaries of these communities and the resulting successional phenomena are considered. Quite a new terminology is presented, many of the terms being synonymous with other more familiar ones.—*C. Regel.*

52. **MØLHOLM HANSEN, H. Livsform og Alder. [Growth-form and age.]** *Bot. Tidsskr.* [*Copenhagen*] 40: 193-203. 1928.—The biological spectrum (Raunkiaer's) of a systematic plant-group, by means of statistics of both palaeobotanic and recent material, is used to determine the relative age of the group. The rule is that of 2 groups the older has the greatest % of Phanerophytes (P %) and the smallest % of Hemicryptophytes (H %), whereas in the younger group the reverse is the case. The distribution of life-forms on different soils is also examined, and the following 2 rules are stated: (1) The individual life-form is associated with definite soil conditions; and (2) A life-form not characteristic of the climate of the region where it exists will here be found in greatest numbers on that soil which is most like the soil of the regions characterized by the said life-form. Changes in the hypsometric curves of the earth's surface are a cause of innovations in the world of organisms during the epochs.—*K. Gram.*

53. **OSBORN, T. G. B. On regeneration problems in arid Australia.** *Proc. 3rd Pan-Pacific Sci. Congress, Tokyo* 2: 1913-1914. 1926(1928).—Climatic and edaphic influences in this region are briefly sketched. There are 3 vegetation types: annuals or ephemerals; trees and tall shrubs; and dwarf shrubs, such as *Atriplex* and *Kochia*. Grazing animals, chiefly domestic, have a serious effect, especially on the dwarf shrubs. Various regressive phases are to be noted, culminating in bare soil.

54. **PATER, B. Über den Standort der Tollkirsche, Atropa belladonna L.** *Heil- und Gewürz-Pflanzen* 13(2): 72-79. 1930.—*Atropa* occurred only in beech forests, where wood had been cut. In woods, in which the beech (*Fagus sylvatica*) is not dominant, *Atropa* does not occur. This was true not only in the woodlands, in the vicinity of Klausenburg, but also in the distant woods of Transylvania, and the mountainous region of Czechoslovakia.—*Author's summary (transl. by C. C. Plitt).*

55. **PIROTTA, PIETRO ROMUALDO. Sulla sviluppo degli studi di ecologia agraria. [Development of studies of agrarian ecology.]** *Mem. R. Accad. Italia Cl. Sci. Fis. Mat. e Nat., Biol.* 1(1): 5-7. 1930.

56. **RANT, A. De Javaansche gebergteflora als bewijs van een vroegere verbinding van Java met het vasteland van Azië. [Mountain flora of Java as evidence of a former connection of Java with the continent of Asia.]** *Natuurk. Tijdschr. Nederlandsch.-Indie* 89(3): 441-468. 1 pl. 1929.—Java, Borneo, and Sumatra are connected with the continent of Asia by an under-sea bank. If the level of the sea were to fall 50 m., this connection of dry land would be established. The former connection of these islands with the continent of Asia was already raised on zoogeographical data. The great similarity of the mountain flora of Java with that of the Asiatic continent gives strong support to this theory. About 60 sp. of dicotyledonous Javanese mountain plants are enumerated which are also found on the Asiatic continent; for about 70 dicotyledonous genera it is shown that closely related sp. of the same genus are to be found in Asia. Furthermore some cases of parasitism and symbiosis of autochthonic Javanese mountain plants are closely related to the parasitism of Asiatic forms (Balanophora; the endotrophic mycorhiza of the Ericaceae; *Exobasidium* on Ericaceae; *Rhytisma* on *Acer*). The transfer of mountain plants from one island to another can only be done by birds or bats; although some cases of endozoic dispersion over shorter distances are known, it is very improbable that it holds good for the mountain plants from one island to another. The transfer through lower regions is improbable, since an investigation of 17 sp. of mountain plants, which were transplanted to the lowland, showed that they very often became sterile and weak. The migration was probably effected during the Pleistocene; the sea-level fell sufficiently and the lower temp. made a transfer in the lower plains possible.—*C. Coster.*

57. **RAUP, H. M. The distribution and affinities of the vegetation of the Athabasca-Great Slave Lake region.** *Rhodora* 32(382): 187-208. 37 fig. 1930.—The geology and glaciation are discussed with principal features of vegetation and affinities of the flora. The most striking feature is the absence of many common sp. of the Canadian forest.—*S. F. Blake.*

58. **SWINGLE, WALTER T. The origin of the flora of eastern Asia, a reservoir of useful plants.** *Proc. 3rd Pan-Pacific Sci. Congress. Tokyo* 2: 1902-1903. 1926 (1928).—It is only in South China and Indo-China that the plants of the temperate and tropical zones can mingle freely. These favored regions have a marvelously rich flora wherein northern and southern plants grow side by side. Recurring famines have forced starving populations to explore to the uttermost the food resources of the local flora. Thus we see here the greatest array of food, medicinal, industrial, and ornamental plants to be found in any similar area.

59. **TAKENOUCHI, MAKOTO. On the influence of volcanic activity upon the vegetation of Mt. Tarumai.** *Proc. 3rd Pan-Pacific Sci. Congress, Tokyo* 2: 1890-1898. Map. 1926(1928).—On Mt. Tarumai (Japan) and vicinity a younger and an older type of vegetation are differentiated by the presence or absence of the destructive effects of volcanic action. Three altitudinal zones of vegetation are distinguished: montane forest, shrub region, and bare region. The vegetation of Mt. Tarumai is now unstable. Eventually it will probably become fixed from the lower to the upper region, attaining at last the condition of Mt. Fuppushinupuri, the summit of which is covered with shrub communities. Remarkable effects of erosion on the vegetation of Mt. Tarumai were also observed.—*From author's summary.*

60. **TAYLOR, GRIFFITH. Agricultural regions in Australia.** *Proc. 3rd Pan-Pacific Sci. Congress, Tokyo* 2: 1657-1662. Map. 1926(1928).—Various ecological regions of Australia are very briefly described, with notes on their agricultural utilization.

61. **TERAZAKI, WATARU. Plant successions in self-**

regenerating forests in various regions of Japan. *Proc. 3rd Pan-Pacific Sci. Congress, Tokyo* 2: 1887-1889. 1926(1928).—Abstract.

62. **TURESSON, GØTE.** The selective effect of climate upon the plant species. *Hereditas* 14(2): 99-152. 25 fig. 1930.—A large number of plants representing different types of 31 sp., collected in different climatic regions, have been transplanted as single spaced plants in experimental fields in southern Sweden; 61 transplant series have been obtained and besides these seed has been harvested from isolated plants, giving 57 seedling generations. Total plant height before fructification and earliness have been chosen to trace the effect of the climate of the following climatic regions: a southern region including central and southern Europe; a northern region, represented by the districts of northern Sweden; a western maritime region, the Faero Islands; and an eastern region, the Altai and East Altai districts. In the 25 aestival sp. the types from the north combine earliness with moderate height, while the southern types are late with great height. The types from the west maritime region combine low growth with lateness, while the eastern types are very early with great height. The alpine types are genotypically lower and earlier than the lowland types. Forms from the extreme north or from alpine regions, when transplanted to southern Sweden, flower earlier and grow taller than in their original habitat; conversely material from the south decreases in height and flowers later than in the wild. These facts do not influence the comparison of the different types, grown together under uniform conditions. In spring plants such as *Caltha palustris*, earliness decreases towards the north; the south German types are earlier than the south Swedish. Still farther to the north, however, earlier types reappear as seen in the Luleaa series from northern Sweden. Problems of climatic differentiation and "acclimatization" in agriculture and forestry are discussed.—*H. Wexelsen.*

63. **WENT, F. A. F. C.** The Pacific Ocean as a boundary of the distribution of the Podostemonaceae. *Proc. 3rd Pan-Pacific Sci. Congress, Tokyo* 2: 1906-1911. 1926. (1928).—Structure and adaptation are discussed in this family, the sp. of which are distributed in tropical waterfalls and rapids from America eastward to Indo-China and Java. Their origin is considered monophyletic. Their distribution indicates a former land connection between So. America, Africa, India, and Ceylon. The Pacific Ocean has apparently been a barrier to their further eastward extension.

64. **ANONYMOUS.** Dix ans d'observations de météorologie forestière en Algérie. *Bull. Stat. Rech. Forest. Nord de l'Afrique* 1(8): 275-330. 1926.—Monthly, quarterly, and annual records of mean, minimum, and maximum temp., mean humidity, mean precipitation, and mean number of days of rain, snow, freezing, frost, hail, rainstorm, sirocco, and wind-storm for 1915-1924 are summarized for 12 stations representing 5 principal forest types: *Quercus suber* at 300-1270 m., *Pinus halepensis* at 850-1530 m., *Quercus ilex* at 1250-1650 m., *Cedrus atlantica* at 1050-1650 m., and *Juniperus phoenicea* at 60 m.—*J. Kittredge, Jr.*

DISEASES CAUSED BY FUNGI

67. **CARTWRIGHT, K. St. G.** A decay of Sitka spruce timber, caused by Trametes serialis, Fr. A cultural study of the fungus. *Great Britain. Dept. Sci. & Indust. Res., Forest Products Res. Bull.* 4. 26p., 6 pl. 1930.—*T. serialis* is a cause of brown pocket rot in Sitka spruce, its action being almost entirely confined to cellulose destruction No signs of discoloration can be observed in many cases. Hyphae may be present the full length of any blocks up to 6 inches long after a period of 4 months, and many of these blocks showed no visible sign of decay; if longer samples had been employed this distance from the visible sign of the rot probably would have been far exceeded. The mode of entry in experimental blocks appears to be usually at the cut ends, though the fungus is capable of entering through the sides. The hyphae grow in the first instance longitudinally through the tracheids. On reaching an area containing the optimum moisture requirements they start to penetrate, probably by means of enzymes secreted at the tips of the actively-growing hyphae. Pits for the most part appear to be ignored, and the hyphae may penetrate through many walls in a straight line at right angles to the length of the tracheids. They may send off branches at intervals, which in turn may penetrate any of the walls both of the tracheids and of the pits. This activity appears principally confined to the medallion type of hyphae. Under optimum conditions the hyphae may be found in masses, but often a few fine isolated strands may run the length of a tracheid, then with more favorable conditions may form a 2nd rot pocket isolated from the 1st by what is apparently sound wood. Brittleness is thought to be caused at an early stage after infection, and if the wood, appearing quite normal when taken from a log, shows any signs of brittleness or discoloration, it is to be regarded with suspicion, especially as the fungus is capable of retaining its vitality and remaining dormant for considerable periods under air-dry conditions.—*From author's summary.*

68. **CHENEY, GWENDOLYN M.** "Black-heart" of apricots in Victoria. *Australian Jour. Exp. Biol. and Med. Sci.* 7(1/2): 91-100. 4 pl., 5 fig. 1930.—A species of *Verticillium* was isolated from a disease of apricot trees in Victoria, characterized by wilting of the leaves and subsequent death of successive branches. The fungus in artificial culture produced small, hyaline conidia at the tips of verticillate branches, dark microsclerotia, and structures resembling chlamydospores. In the host tissues the mycelium was found in the younger wood vessels, the hyphae passing from one vessel to another through the pits. Characteristic is the production of a brown, gummy substance in the older vessels. Young trees were inoculated by introducing mycelium into the branches but no symptoms of disease resulted. Inoculation of the roots (2 trees) with a spore suspension produced symptoms in 6-8 weeks. Sections taken from a branch of a tree showing symptoms produced in this manner gave a growth of *Verticillium* in culture. Prolonged culture of the fungus on artificial media pro-

r.—This is a metaphysical study for which drawn from the border sciences, both natu- nistic. The presuppositions are that both acquisitional qualities are hereditary. The quisition passes from the soma to the germ logical, prehistoric, and historic studies are ace and time to show the doctrine of volution." EY, ARTHUR WARD. The problems of 5p. Macmillan Co.: New York, 1931. Pr. uthor approaches the problems of evolu- standpoint of the effects of the environ- ndividual and the race, though disclaiming bias. Attention is centered on the nature species. The species, since it is composed , is the product of definite interacting nvironment. Taxonomically it is a mental of a line of evolution. Phylogenetically it nly the individuals extant at a given time, succession of generations before it loses he species is sharply limited in space, but e. Species are genetically diversified and diverse environments with resulting modi- lividuals and the evolution of geographical sponses in individuals to environmental part of the problem of evolution. Change emanates from all phases of the environ- m the heritage, but whatever its source, nges invariably concern both heritage and There is no reason either to suppose that istments to fluctuating environments must haracters of the species, or that they may so fixed. Since chromosomes and genes s active in controlling the functions of the t its life, there is every reason to believe also the capacity for increase or decrease s as a result of the degree of activity de- m. The evolutionary theories of selection, tion, and parallel induction are reviewed usion reached that: given variation, it is elective and isolating factors contribute to of species into geographic races which are es. Hybridization may play a part in the f existing characters also. But when we at- nt for the origin of variations we can only ons or to individual response to environ- ling line between which is not clear. Evo- lative change is evident in nature in fossil dividual responses. The close parallel be- tive responses in individuals and the adap- in species suggests that adaptation in spe- lly haphazard at the outset, that it does lly upon random mutations, but that it is lasticity of the living substance. The in- ts an adequate environment as well as the organic foundations for its development. Heritage, internal environment and the physical and organic factors of the external environment are all operative in shaping the course of the development of the individual. To say that heritage is the source of all evolutionary change in living things is a recognition of the control it has wrested from the environment, and of the degree of self-[illegible] it has attained, but at the same time it is a failure to give recognition to the part environment continues to play. Adjustment is the price of existence. The results in evolution must necessarily be slow, but this is clearly the direction which investigations in the future must take. The tendency of heritage is not toward change.—*C. A. Kofoid.*

23. OSBORN, HENRY FAIRFIELD. From the Greeks to Darwin: the development of the evolution idea through twenty-four centuries. 2nd ed. xvi+398p. Chas. Scribner's Sons: New York & London, 1929. Pr. $2.50.—This edition, revised and extended to embrace recent work, has involved a complete restudy of the entire 24-century period of evolutionary thought; many new lines have been traced in the lineage of ideas, previously undiscovered anticipations of Darwinism have been unearthed, and the work of certain authors has been more fully and critically examined. Additional proofs are included, that the evolutionary idea is in itself a product of 24 centuries of evolution. The volume purports to be a history of ideas and only to a small extent a history of personalities. The subject matter is discussed under the following chapter headings: The anticipation and interpretation of Nature, in which the author surveys the subject and its background in science and philosophy; Among the Greeks; The evolution idea among the theologians and natural philosophers; The evolutionists of the eighteenth century; From Lamarck to St. Hilaire, Goethe and Naudin; Darwin; and a final chapter entitled: Retrospect. A 12-page bibliography and a 20-page index are included.

24. PAUL, A. Zum Problem der menschlichen Metamorphose. 74p. Otto Hillman; Leipzig, 1928.—With a strong Lamarckian bias this short volume defends the thesis that, from a primitively homogeneous race of mankind, climatic conditions have brought about and are maintaining the racial characteristics as we see them today. Exposure to the sun's rays is the chief factor in race formation, and this is modified chiefly by humidity and the effect of oceans and inland seas. Africa and its negro population is first discussed, then the more complex conditions of Europe are analysed, the Mediterranean, the North Sea, the Alps, the Gulf Stream being given their respective race-forming values. Culture, religion, and language share with physical characters a subordination to and dependence upon climatic-atmospheric conditions. The influence of physical heredity is considered but is relegated to the background. Two apparent obstacles to the theory, the melting pot of America and the widely distributed Jewish race, are given considerable attention. While in neither case has there been sufficient time for very evident changes to have occurred, the author yet argues that careful observation does disclose some changes in Jews, both cultural and physical, towards the human types in whose midst they may have settled; and the further assertion is made that already the American Indian physiognomy may be detected in certain "Mayflower" Americans.—*C. G. Hartman.*

25. **AREY, LESLIE B. New diagrams illustrating the transformation period of the human spermatid, as prepared by the late Professor Bowen.** *Anat. Rec.* 47(1): 31-38. 11 fig. 1930.—A series of 11 semidiagrammatic drawings prepared by R. H. Bowen as a text-book figure to illustrate the cytological changes taking place during the formation of a mature human spermatozoon. As far as possible, these illustrations are based on facts established for man; they are further supplemented, with appropriate discrimination, by data from other mammals. Accompanying the diagrams are some miscellaneous explanatory notes.—*Author (courtesy Wistar Bibl. Serv.)*

26. **FAULKNER, G. H. The early prophases of the first oocyte division as seen in life, in Obelia geniculata.** *Quart. Jour. Microscop. Sci.* 73(2): 225-242. 23 fig. 1929.—The nucleolus of the resting oocyte represents a condensed chromatic spireme, hence it is identical with the total chromosomal contents of the nucleus. During the early growth phases, the nucleolus elongates and fragments. Each fragment has been identified as a pair of homologous chromosomes indistinguishably united; later each of these bivalent elements divides, and the individual chromosomes are thus separated. The two components of the largest bivalent element are unequal in size, and probably represent an *XY* pair. The chromosomes can be counted either at the bivalent or at the univalent phase, the numbers being 17 and 34, respectively. At a still later stage the chromosomes fragment into numerous small globules, which become evenly distributed over the nucleus. The whole account is based on observations on living oocytes.—*Author's summary.*

27. **HUETTNER, ALFRED F. The spermatogenesis of Drosophila melanogaster.** *Zeitschr. Wiss. Biol. Abt. B. Zeitschr. Zellforsch. u. Mikrosk. Anat.* 11(3/4): 615-637. 51 fig. 1930.—The difficulties encountered in studying the spermatogenesis of *D. melanogaster* in regard to pseudo-chromatic inclusions in the nucleus and cytoplasm have been eliminated by the Feulgen nuclear reaction and other special cytologic methods. From the early growth period of the primary spermatocyte to the leptotene stage, the chromatin is indistinguishable because of diffusion. The larger nucleolus present in the primary spermatocyte, and other nuclear inclusions which stain black with hematoxylin, have nothing to do with the chromosomes. A definite leptotene stage is present, but there is no polarization of threads. Synapsis is incomplete, abortive and of brief duration. Meiotic divisions are typical. The 1st judging by the behavior of the lagging sex chromosomes is reductional. Interkinesis is very brief. The *XY* pair is never as closely apposed as the components of the autosomal tetrads. Conclusions derived from this investigation substantiate the genetic evidence that there is no crossing-over of factors in the ♂ of *Drosophila melanogaster.—Author's summary.*

The effect of the i secretions upon the division energy of paramoecia** *Cancer Res.* 14(4): 509-515. 1930.—The action of rious endocrines upon the division energy of para was found to vary—spleen, liver, thymus, suprare testes stimulating; thyroxin, insulin, pituitary an thyroid inhibiting; and ovary having no influe

30. **TURNER, JOHN P. Division and conjuga Euplotes patella Ehrenberg with special reference nuclear phenomena.** *Univ. California Publ. Zool.* 193-258. 12 pl. 1930.—During division the old cy remains unchanged. Feeding continues through process and commences in the posterior daughte fission is complete. All cirri and the neuromote of the anal cirri are replaced de novo. A do organization band passes through the C-shaped nucleus from each tip to the middle, where the unite and disappear immediately before maer contraction, which precedes fission. These ba cause colloidal phase reversal. During divisi micronucleus 8 rod-shaped chromosomes appea dosome is present. During conjugation, all t ganelles and the neuromotor fibers of the anal replaced de novo. The micronucleus undergoe liminary division and 2 maturation divisions, f nuclei. Of these, 6 degenerate while 2 undergo maturation division forming the 2 pronuclei an tional degenerating nuclei. The first maturation involves a complicated series of changes inclu formation of about 32 chromomeres. No metaph of chromomeres occurs, 16 passing to each pole. tion occurs in the second maturation divisio 8 chromosomes appear, unite in pairs and later 4 chromosomes passing to each pole. The wander nucleus breaks out of the left anterior margin parent body and migrates into the apposed co In each pronucleus 4 chromosomes are seen. As jugants separate, the amphinucleus divides twic ing 8 chromosomes each time, forming 4 grand nuclei, one of which condenses as the new micr one undergoes a characteristic enlargement and formation and is the new macronuclear anlage. T 2 eventually degenerate. The new macronucleu fuses with a reconstituted portion of the old one the new macronucleus. Epidemics of conjugation cultures have shown as many as 75% of the orga nearly the same stage of the process.—*J. P. Tu*

duced a saltant, which differed from the normal form in the absence of microsclerotia.—*From author's summary.*

69. FALCK, RICHARD. Neue Mitteilungen über die Rotfäule. [New data on the red rot.] *Mitteil. Forstwirtsch. u. Forstwiss.* 1(4): 525-566. 12 fig., 4 pl. 1930.—The so-called red rot of spruce includes the rot (*Agaricus melleus*) of the root-stock, and the stem rot (*Polyporus annosus* (=*Trametes radiciperda*)). Both occur in the forest as pure saprophytes on dead wood and leaf litter, semi-parasites on the practically dead heartwood of living trees, and as true parasites on the cambium and outer sapwood. The stem rot seldom attacks healthy trees, but usually follows after the tree has been weakened by the root rot. In the forests that were studied, the 2 diseases caused a volume loss of 10.2-28.5% and a loss in timber value of 2.6-21.2%. Loss from stem rot can be reduced by maintaining the soil in a healthy state; by keeping down other diseases and pests; by selecting resistant strains of spruce, and by not letting trees, suppressed in youth, become the dominant ones of the older stand as a result of thinning. There is also some prospect that spread of the rot above the root collar can be checked by injecting chemicals into the base of the trees. Attempts to eradicate the 2 fungi are not recommended, because they are valuable agents in breaking down the dead wood and leaf litter, thus keeping the soil healthy.—*W. N. Sparhawk.*

70. KOCH, L. W. Spur blight of raspberries in Ontario caused by Didymella applanata. *Phytopath.* 21(3): 247-287. 11 fig. 1931.—Spur blight is almost universal, occurring in North America, Europe, and Australia. It is becoming more prevalent in the Niagara peninsula (No. Amer.). In Europe damage caused by spur blight is reported to be extensive, especially in Germany and Switzerland. In America it appears to cause considerable damage in the U. S. A. and Canada. In the summer the most striking symptoms are purplish brown discolorations on the canes and similar lesions on the leaves and buds. Diseased canes turn light gray in color during the winter following infection. Perithecia become increasingly conspicuous on the lesions during the winter and spring. In America spur blight has been attributed to *Mycosphaerella rubina*, and in Europe a similar disease is considered to be caused by *Didymella applanata*. Mature perithecia collected in Ontario and some from the original material from which *M. rubina* was described were sectioned, the 2 being identical with paraphyses present in both. Cultures, natural infections, inoculations, and reisolations indicate the 2 species are identical. A description of the perithecial and pycnidial stages of *D. applanata* and the results of isolations from each stage are given. Perithecia belonging to *D. applanata* developed on canes inoculated with cultures originating from ascospores of the same species. The canes, prior to the formation of perithecia of *D. applanata* developed pycnidia belonging to a *Phoma* sp., which is the imperfect form. The *Coniothyrium*, at times found associated and reported genetically associated with *D. applanata*, is the imperfect stage of *Leptosphaeria coniothyrium*. The growth rates of the *Phoma* stage on 8 different nutritive media at various constant temp. are stated, growth occurring within the range 2-28° C. Perithecia of *D. applanata* discharged their ascospores in 1929 from May 7–July 7, rain being a prerequisite. Pycnospores of *Phoma* sp. were discharged at intervals along with the ascospores. Infection resulted from the inoculation of both uninjured and injured canes with ascospore suspensions of *D. applanata*. Various portions of the plant, including fruit spurs, tips of canes, and developing buds, proved to be susceptible. Leaves were also inoculated with ascospore suspensions of *D. applanata* and pycnospore suspensions of *Phoma* sp., and symptoms appeared on both injured and uninjured leaves. 22 varieties of red and black raspberries were found to be more or less susceptible. All regions of the host cortex except the cork were freely penetrated by the mycelium. The host produces no visible barrier to withstand invasion. Perithecia of *D. applanata* were observed on the surface of bud scales in the spring. A 3-5-40 Bordeaux mixture, to which was added 2 lb. of whale-oil soap, was employed in attempting to control spur blight. Over a period of 2 yr. an average control of 80.4% was obtained with a single application.—*Author's summary.*

71. LIESE, I. Beobachtungen über Stamm- und Stockfäulen unserer Waldbäume. *Zeitschr. Forst- u. Jagdw.* 62(7/8): 579-591. 5 pl. 1930.—In living pines the principal fungous decay is due to *Trametes pini*. The 3 less well known but destructive diseases [*Polyporus schweinitzii* (=*P. sistotremoides*), *Sparassis crispa* (=*S. ramosa*) and *Merulius silvester*] are described, with especial emphasis on the character of injury which they induce. *P. annosus* (=*T. radiciperda*) has never been found as a cause of stump rot. Likewise *Lentinus squamosus* (the cause of pure heart rot of impregnated sills) could not be associated with attacks on green pine stumps. A canker recently discovered near the base of an oak tree in a private forest near Königswusterhausen was found to be associated with *Stereum rugosum*, which starts life as a saprophyte, but becomes parasitic with age and availability of host material. It attacks the stem through wounds, preferably through broken branch stubs.—*J. Roeser, Jr.*

72. PRIODE, C. N. Observaciones adicionales sobre la enfermedad Pokkah-bong de la caña de azucar en Cuba. [Pokkah-bong disease of sugar cane in Cuba.] [In Spanish and English.] *Memoria Conf. An. Asoc. Tec. Azucar Cuba* 3: 106-114. 6 fig.; English 98-106. 6 fig. 1929.—The symptoms of this disease, which is caused by *Fusarium* sp., are very characteristic and not easily confused with other cane diseases once they are known.

73. RAVAZ, L. La fumagine. *Progrès Agric. et Vitic.* 94(41): 341-343. 1 col. pl. 1930.—Note on sooty mold of grape (*Fumago vagans*), with control.

74. RHOADS, A. S. Bark-rot [fungous] of orange trees. *U. S. Dept. Agric. Bur. Plant Indust. Plant Dis. Rept.* 14(17): 169. 1930. [Mimeographed.]

75. ROEPKE, W. Verdere gegevens omtrent de iepenziekte en den iepenspintkever. [New facts about the elm disease and the elm bark beetle.] *Tijdschr. Plantenziekten* 36(9): 232-237. 2 pl. 1930.—Field observations showed that *Graphium ulmi* is present in the dead bark of elm trees. Coremia are often found in the pupa chambers. The beetles coming out of the bark are easily infected. Near scars of feeding places of young beetles symptoms of the disease could be observed. Control of the elm disease depends on control of the beetles. This can be done by cutting all trees which are already attacked and by preventing the attack of healthy trees.—*H. L. G. de Bruyn.*

76. SMITH, RALPH E. The life history of Sclerotinia sclerotiorum with reference to the green rot of apricots. *Phytopath.* 21(4): 407-423. 6 fig. 1931.—The "green rot" disease of apricots and almonds, an infection of young fruits through adherent, dried calyces, occurs in a very sporadic manner in central California. The usual cause of the disease is *S. sclerotiorum*. *Botrytis cinerea* is commonly associated with affected material. Moist-chamber tests of blossoms of apricot and other fruits, as well as those of many annual plants, from many places in central California, showed that from about February 15–June 15 *S. sclerotiorum* was universally present on vegetation. This was true during 2 seasons (1929 and 1930) when no green rot appeared, when no development of *S. sclerotiorum* (save in minor instances) on surface-growing plants was observed, and in situations where the vegetative growth of this fungus was extremely unlikely. No evidence was found to suggest that *S. sclerotiorum* possesses a conidial stage of *Botrytis* or any other type. It would appear that the aerial distribution of this fungus is much more general than has hitherto been suspected.—*From author's summary.*

77. THOMAS, K. M. A new paddy disease in Madras. *Madras Agric. Jour.* 19(1): 34-36. 1 pl. 1931.—A preliminary report of a disease affecting the 2nd season crop

beetle, *Empoasca mali, E. flavescens, Cicadula 6-notata, Rhopalosiphum persicae,* and *Microsiphum solanifolii,* when transferred from yellows-infected plants of *E. canadensis* and caged on healthy peach trees, failed to transmit any symptoms of disease to the peaches. More than 100 mechanical inoculations into peach shoots and green fruits, made with a hypodermic needle and a fresh undiluted extract from yellows-infected plants of *E. canadensis,* gave entirely negative results. Transmission of rosette from plum to peach and sand cherry by infected buds was 100% effective. The results of mechanical transmission experiments with the causal agent of rosette from sand cherries to *E. canadensis* were entirely negative. Attempts to transmit the causal agent of rosette from sand cherries to *E. canadensis* by the green peach aphid (*R. persicae*), the black peach aphid (*Aphis persicae-niger*), the melon aphid (*A. gossypii*), the common mealy bug (*Pseudococcus citri*), and the tarnished plant bug (*Lygus pratensis*) all proved negative. Bud transmission of the causal agent of rosette from sand cherries to plums was 100% effective. Aster yellows of *E. canadensis* is a disease distinct from rosette of peach, plum, and sand cherry.—*Author's summary.*

NON-PARASITIC DISEASES AND TERATOLOGY (INCLUDING DISEASES OF UNKNOWN CAUSE)

91. DÖRING, HERMANN. Zur Kenntnis der Knöllchensucht. *Angewandte Bot.* 11(3): 246-267. 2 fig. 1929.—A study of the abnormality of potatoes sometimes referred to as "tubers but no tops" is presented, beginning with a discussion of the various explanations of this phenomenon. Development of tubers from the mother tubers has been induced by means of chemical treatment. These newly formed tubers may be sessile on the mother tuber, on short stolons, or sometimes on stems above the ground. Of the various chemicals tried, chinolin (quinoline distilled from tar oil) used at a strength of 1% gave the most marked development of tubers, the fraction distilling above 250° C. being the most effective. The treatments were made by inserting a glass tube 10 cm. long and 6 mm. bore into the middle of a tuber for a depth of 15 mm., removing the core and then reinserting into the tuber, after which it was filled with the solution of the chemical to be tested. The tests were carried out in a dark cellar at 18° C., with the tubers in boxes filled with a moist mixture of washed peat moss and quartz sand. Marked differences in response to the treatments were shown by different varieties of tubers, and the most marked development of new tubers was obtained when the test tubers were the nearest the beginning of their rest period; hence, late varieties gave a better response than early ones.—*F. D. Heald.*

92. FALCONER, ALLAN. Fog in relation to glasshouses. *Gard. Chron. [London]* 89(2301): 84. 1 fig. 1931.—Comments on the injurious effect in industrial areas of fog on vegetation, due to toxic substances and to interference with light.

93. LIERNUR, A. G. M. Bijdrage tot de kennis der heksenbezems [Witches' brooms.] *Tijdschr. Plantenziekten* 36(9): 229-231. 1 fig. 1930.—A description is given of a large, round witches' broom of elm found in Tilburg. Next to this type with small short conical branches on which normal branches again develop, there exists another round type with conical thickened branches, from which long branches develop with abnormal internodes (nest type).—*H. L. G. de Bruyn.*

94. RIETSEMA, J. Weinig bekende ziekten in kers, pruim en perzik. [Little known diseases of cherry, prune and peach trees.] *Tijdschr. Plantenziekten* 36(11): 261-269. 4 pl. 1930.—The occurrence of cherry, prune, and peach trees with abnormal leaves is noted and the malformations of the leaves are described in detail. The disease is called vitrose and the possibility of its being a virus disease is considered. Another disease mentioned is mottling of the leaves, which might be a form of mosaic. Prune trees with vitrose are not certifiable.—*H. L. G. de Bruyn.*

DISEASE RESISTANCE AND PARASITISM

96. BRESSMAN, E. N. Rye infected with bunt of wheat. *Phytopath.* 21(4): 437-440. 2 fig. 1931.—At Corvallis, Oregon, only *Tilletia tritici* p. f. 9 was able to affect rye and then only Oregon selection no. 1 and Rosen rye. Similar results were obtained at Pendleton, Oregon. No dwarfing of the bunted heads was observed. In cases where floret sterility was present, bunt balls were found in practically all florets. The infection of rye was typical to that produced on wheat by the same organism.—*W. A. Whitney.*

97. DICKINSON, LAWRENCE S. The effect of air temperature on the pathogenicity of Rhizoctonia solani parasitizing grasses on putting-green turf. *Phytopath.* 20(8): 597-608. 3 fig. 1930.—The optimum temp. range for the growth of the short mycelia from sclerotia is 64-68° F., and the required duration of temp. within the range is variable. If the optimum temp. is reached from a lower temp., the air must remain nearly constant for 8-10 hr. to permit growth of sclerotia. The mycelia will appear in 30-60 min. after cooling to the optimum temp. The development of the fungus to the point of becoming actively parasitic is concurrent with a rise in air temp. Virulence appears to require a rather rapid rise from 64-68° F. to 80-85° F. Parasitism commences at about 73° F. and ceases at 90° F. If the air temp. falls below 62° F. the mycelia on the sclerotia are destroyed. No relation could be determined between the humidity records as made and the appearance of large brown patch. Likewise, rainfall and the amount of sunshine failed to show any degree of correlation. From laboratory experiments, 20° C. appears to be too cool for vigorous mycelial development; mycelial development is retarded by a rise in air temp. to 35° C. Chilling appears to be essential for growth of sclerotia if the air is warmer than 35° C., and mycelial growth in all cases was weak at the time of the 1st observations and could be destroyed very easily by attrition or a fungicide. In pot experiments, the growth of sclerotia was hastened and increased if the sclerotia were cooled to the optimum range for 45 min.; 60% of all sclerotia that were chilled showed short mycelial growth at the end of the chilling period; no sclerotia kept at a constant temp. showed mycelial growth at a corresponding time. Moisture is favorable to growth but not of vital significance. Sclerotia grow better and the mycelial development is greater when they are in contact with soil than when they are on grass.—*W. A. Whitney.*

98. KÖHLER, E. Die Züchtung krebsfester Kartoffelsorten. [Breeding of potatoes resistant to wart disease.] *Züchter* 1(1): 16-20. 3 fig. 1929.—An immune variety is said to be immune under all environments, and no differential strains of the pathogen have been observed. The chief contribution is the outline of a method for testing resistance to wart, especially in the greenhouse.—*F. V. Owen.*

99. McDONALD, J. Notes on physiologic forms of wheat stem rust in Kenya and their bearing on wheat breeding. Union So. Africa Dept. Agric. Pan-African Agric. & Vet. Conf. Pretoria Papers Agric. Sect. p. 242-244. 1929.—A popular summary of principles and methods employed.—*W. A. Whitney.*

100. MARCHAL, ÉMILE. Le facteur météorologique dans l'évolution des maladies cryptogamiques. [The meteorological factor in the development of fungous diseases.] *Rev. Gén. Hort. [Paris]* 8(86): 1402-1404. 1930.

101. ROEDER. Zur Frage der Kienzopfverbreitung. [Distribution of Peridermium pini.] *Zeitschr. Forst- u. Jagdw.* 62(4): 241-242. 1930.—In the pine stands in the forest range of Runkel on the Lahn, infection in young, otherwise healthy, stands occurs as the result of injury to the bark by rubbing and whipping branches. Practically no further infection could be identified following 2 thinning operations. Older stands (60-80 yrs.) are

almost entirely clean. On the other hand, the disease is heavy in a 25 to 27-yr.-old stand started from seed of undesirable origin which has produced a stand of characteristically short, wide-spreading "wolf" trees. Infections, which are numerous, can be definitely traced to bark injuries, being favored also by the succulent texture of the bark of the rapidly growing trees. A relation between predisposition to infection and source or racial strains is indicated.—*J. Roeser, Jr.*

102. SNELL, K. Die Entwicklung der deutschen Kartoffelzüchtung in den letzten fünf Jahren. *Züchter* 1(7): 224. 1929.—The German Registration Commission has designated several potato varieties as identical, the number recognized being reduced to 137. The chief interest in connection with the development of new varieties has been a yellow-fleshed potato resistant to wart.—*F. V. Owen.*

103. STRAIB, W. Die Bewertung und Bedeutung künstlicher Rostinfektionsversuche für die Pflanzenzüchtung, mit besonderer Berücksichtigung des Gelbrostes. *Züchter* 1(7): 217-223. 1929.—Temp. was found to be one of the most important factors in infection by *Puccinia glumarum*. In a controlled experiment with temp. held at 20-22° C. there were a few susceptible varieties of wheat, but most were resistant; at 8-12° all varieties were susceptible and most of them were severely infected; at 14-16° C. there was a distinct separation between susceptible and resistant varieties, with the majority of varieties susceptible. This effect of temp. in greenhouse studies was corroborated by field results. Without knowledge of proper temp. control a variety of wheat may be as likely to appear susceptible as resistant. The development of *P. graminis* was also found to be affected by temp., but not nearly so markedly as *P. glumarum*. Brown rust of wheat and crown rust of oats were not affected materially by temp.—*F. V. Owen.*

104. TAUBENHAUS, J. J., WALTER N. EZEKIEL, and J. P. LUSK. Preliminary studies on the effect of flooding on Phymatotrichum root-rot. *Amer. Jour. Bot.* 18(2): 95-101. 1931.—Root-rot (*P. omnivorum*) is extremely uncommon in bottom lands, in soils apparently favorable for the development of the disease, even in regions in which the disease is prevalent in the adjoining fields. Root-rot was introduced into a creek bottom by the artificial inoculation of cotton plants, and reappeared in the year following the inoculation. In a laboratory experiment, strands of *P. omnivorum* on naturally-infected cotton roots were inactivated by submergence in saturated soil for more than 3 days; while with parallel series, at the same temp. but stored in moist air, the fungus was still viable after 2 weeks and still able to infect normal cotton plants. Flooding experiments in the field, during 3 seasons and continuing for as long as 120 days, failed to produce significant changes in the survival of root-rot or to eliminate roots of root-rot carriers from the soil. The survival of root-rot in these experiments is explained as due to possible lack of deep penetration of the water, and to the possible presence of sclerotia which are able to survive long periods of immersion.—*Authors' summary.*

105. THOMAS, K. M. A practical method of estimating disease resistance in crop plants. *Madras Agric. Jour.* 19(1): 16-23. 1931.—The author presents a method, successfully employed, for determining the disease resistance of paddy varieties to blast, of sugar cane to mosaic, and of ground nuts to wilt. With modifications the method promises to be useful for other diseases. It consists essentially in (1) growing varieties and strains under natural conditions and under identical environment, (2) providing identical exposure of all varieties to infection and natural development of the disease, (3) growing a sufficiently large number of individuals to obviate errors, (4) close study of an equal number of individuals in a variety and a correct estimation of disease incidence, and (5) evaluation of the extent of disease and the loss due to it among the several varieties under trial.

DISEASE CONTROL (SEED TREATMENT, SOIL DISINFECTION, FUNGICIDES, AND SPRAYING)

107. BODNÁR, J., und ALEXANDER TERÉNYI. Biochemie der Brandkrankheiten der Getreidearten. II. Biophysikalische und biochemische Untersuchungen über die Kupferadsorption der Weizensteinbrandsporen (Tilletia tritici (Bjerek.) Winter). *Hoppe-Seyler's Zeitschr. Physiol. Chem.* 186(4/6): 157-182. 4 fig. 1930.—Cu from $CuSO_4$, $Cu(C_2H_4O_2)_2$, and $CuSO_4(NH_3)_4$ solutions is absorbed by the spores in the relative and absolute ratio of 1:2:3; that from solutions of the first 2 salts being held in the walls as albuminate and phosphate while the $Cu(NH_3)_4$ ion penetrates into the protoplast, which it kills. Recovery of germinating ability occurs after treatment with $CuSO_4$ or $Cu(C_2H_4O_2)_2$ solutions if the spores are sown upon moist earth or gelatine which absorb the Cu from them or if they are washed with 0.5% HCl and sown upon 0.1% $Ca(NO_3)_2$ solution. Difficulty in removing the Cu from the spore walls increases with increase in concentration of the salt and in time of treating. Treatment for 15 min. is effective in inhibiting germination if 0.5% Cu is absorbed by the spores, for 24 hr. if 0.3% is absorbed. The inhibiting effect of dilute solutions of $CuSO_4$ was observed only when the proportion of spores to Cu present was such that 0.5% or more copper would be absorbed by the spores. Neither $ZnSO_4$ nor NaCl increased the amount of Cu absorbed or the inhibiting effect.—*J. W. Sinden.*

108. BROADFOOT, W. C. Preliminary experiments on the control of cereal rusts by Kolo dust. *Phytopath.* 21(4): 347-372. 1931.—Experiments to control cereal rusts by Kolo dust were carried out at Morris, Crookston, and St. Paul, Minnesota, in 1927, using the varieties of wheat which are extensively grown in Minnesota, such as Marquis and Ruby (bread wheats) and Mindum (a durum wheat). There were over 2,000 plots in the entire experiment at these 3 stations. The data from the Marquis plots dusted 3 times show as high as 80.2% reduction in the amount of stem rust; 57.1% increase in yield; and 13.7% increase in weight per bushel, as well as an increase in the grade of wheat when compared with that of control plots. The most effective dusting schedules for 3 applications, from the standpoint of timeliness of application, was one made at flowering time followed by a second 6 days later and a third 4 days after the second, or one made at flowering time followed by a second after 8 days and a third 4 days later. The 15- and 30-lb. rates (per acre) were essentially as effective as the 45- and 60-lb. rates. The data from the Marquis plots dusted twice with Kolo dust show as high as 50.3% decrease in stem rust, 39.7% increase in yields and 10.8% increase in weight per bushel, as well as an increase in grade. The most effective schedule for 2 applications was one dusting at flowering time and the second 6 or 8 days later. The 15- and 30-lb. rates were nearly as effective as the 45- and 60-lb. rates. For practical purposes 2 applications were almost as effective as 3, and the 15-lb. rate was nearly as effective as the 60-lb. rate. Although there was no significant evidence of stem rust control with 1 application of Kolo dust, the treated plots frequently yielded slightly more, and graded slightly higher than the control plots. When Marquis wheat plots were dusted with Kolo dust at the 30-, 45-, and 60-lb. rates at 3-, 5-, 7-, 9-, and 11-day intervals, starting at flowering time, the upper limit for length of time lapsing between applications was found to be 9 days. In Marquis wheat plots dusted with Kolo dust at the 60-lb. rate before, during, and subsequent to flowering time, there was no evidence of injury to setting of seed. Where Kolo dust was applied broadcast to the soil between the rows of Marquis or Mindum at flowering time, in amounts ranging from 30-1,920 lb. per acre, there was no observable control of stem rust, no increase in yield, weight per bushel, or grade of wheat. Ruby wheat dusted 7 times with Kolo dust at the 60-lb. rate at 5-day intervals yielded 26.7% more wheat than control plants. This increase in yield, as well as an increased weight per bushel and grade, was ascribed to the marked decrease in the amount of orange leaf rust, since there

was very little stem rust in the Ruby plots. The protein content of wheat from the non-dusted plants was found to be slightly higher than that of the dusted plants, being 15.16 and 14.80%, respectively.—*From author's summary.*

109. DETWILER, S. B. The white pine blister rust situation. *Jour. Forest.* 29(2): 181-185. 1931.—White pine blister rust is now established on at least ¾ of the area of the commercial 5-needled pine forests of the U. S. A. Mature stands as well as young trees of western white pine will be destroyed rapidly if *Ribes* spp. remain in the forests. To be effective, eradication must be done early, before infection, which takes about 3 yr. to become evident, has taken place.—*P. C. Wakeley.*

110. DILLON-WESTON, W. A. R. Ineffective nature of iodine dust as a fungicide against Tilletia caries. *Phytopath.* 20(9): 753-755. 1930.—Treatment of artificially inoculated Little Joss wheat with 1.5, 3, and 5% iodine dust, at the rate of 2 oz. to the bushel, with untreated and copper-carbonate treated lots as checks, showed iodine dust to be of no value as a fungicide for *T. caries.*—*W. A. Whitney.*

111. FOSTER, J. R. Witch broom control. Progress report. *Proc. Agric. Soc. Trinidad & Tobago* 30(7): 259-260. 1930.—A general decrease of brooms in coco plantings in all the affected areas is noted.

112. GOODWIN, W., H. MARTIN, and E. S. SALMON. The fungicidal properties of certain spray-fluids. 7. *Jour. Agric. Sci.* 20(3): 489-497. 1930.—The fungicidal properties of solutions containing S in polysulphide form—Na-, K-, Ca- and Ba-polysulphides—were tested by application to the conidial stage of *Sphaerotheca humuli* growing upon young hop leaves in the greenhouse. 4 samples of Na polysulphide solutions, 2 prepared in the laboratory and 2 commercial products, were examined. When applied with 1% soft soap as a spreader, solutions containing 0.5% polysulphide S proved fungicidal. With 0.5% gelatine as the spreader, fungicidal strength did not begin to be attained until the concentration of polysulphide S reached 0.11%. The results suggest that the nature of the spreader may influence the fungicidal properties of polysulphide S. 2 samples of K polysulphide solutions prepared in the laboratory had an action similar to that of Na polysulphide solutions when applied at the same concentration of spreader and polysulphide S. 4 samples of Ca polysulphide solutions including one commercial lime sulphur proved almost or quite fungicidal at concentrations of 0.11% polysulphide S when applied with 0.5% gelatine. 2 laboratory-prepared Ba polysulphide solutions proved almost or quite fungicidal at a content of 0.11% polysulphide S when applied with 0.5% gelatine. Solutions of Ca polysulphide which differed widely in the relative amounts of total and thiosulphate S behaved as fungicides in accordance with the polysulphide S content only. The fungicidal efficiency of the polysulphide S was shown to be independent of the base with which it is combined. The results confirm the view that the polysulphide S content is a measure of the fungicidal power of spray-fluids of the polysulphide class.—*Authors' summary.*

113. HUS, P. Proeven met verschillende middelen tegen appelschurft (Fusicladium dendriticum). [Experiments with different fungicides for apple scab.] *Tijdschr. Plantenziekten* 36(12): 286-288. 1930.—Good results were obtained with 4 applications of 2.5% lime-sulphur and by dusting with kolotex and kolodust.—*H. L. G. de Bruyn.*

114. JOCHEMS, S. C. J. Verslag van een proef om door middel van sterilisatie met stoom zaadbedden vrij van slijmziekte te maken. [Steam sterilization of tobacco nursery beds against bacterial wilt.] *Vlugschr. Deli Proefstat. Medan* 48. 1-6. 1 fig. 1930.—On some tobacco estates in Deli (Sumatra) seedbeds of tobacco are attacked by wilt (*Bacterium solanacearum*). In order to get seedlings free from disease the beds were heated with low pressure steam by the box and grid method. A plant was designed to make sterilization feasible on a commercial scale, one estate laying out about 10,000 seedbeds. Sterilization was applied for 45 min.; minimum depth of sterilization was 30 cm.; temp. reached 90° C. Comparisons were made between plants from diseased beds, from beds from soil free from disease, and plants from sterilized beds. The latter gave results as good as beds from disease-free soil; the growth on sterilized beds was often better and especially more even.—*J. Kuijper.*

115. LIESE, J. Neue Wege zur Bekämpfung des Kienzopfs (Peridermium pini). *Zeitschr. Forst- u. Jagdw.* 62(1): 47-48. 1930.—In the Chorin provenance plantations, artificial aecidiospore inoculations were successful only when the inoculated tree showed symptoms of "Kienzopf." The results indicate a variable individual susceptibility and an inheritance of a disposition to contract the disease. It is desirable to avoid all badly diseased stands when seed is collected, in fact, the taking of cones from diseased trees should be prohibited.—*J. Roeser, Jr.*

116. McCALLAN, S. E. A. Studies on fungicides. II. Testing protective fungicides in the laboratory. *Cornell Univ. Agric. Exp. Sta. Mem.* 128. 8-24. 2 fig. 1930.—Details are given of a method of evaluating the relative toxicity of protective fungicides which consists in the determination of the inhibition of germination of fungus spores placed on glass slides coated with the fungicide and incubated in moist chambers. The necessity for controlled and standardized conditions and the method of application of the fungicide and recording of results are discussed in detail.—*S. E. A. McCallan.*

117. McCALLAN, S. E. A. Studies on fungicides. III. The solvent action of spore excretions and other agencies on protective copper fungicides. *Cornell Univ. Agric. Exp. Sta. Mem.* 128. 25-79. 4 fig. 1930.—The toxicity of $CuSO_4$ solutions to conidia of *Sclerotinia americana* as measured by inhibition of germination was positively correlated with total Cu content and negatively with number of spores. Increasing the volume of solution containing a definite amount of Cu and spores diminishes its toxicity because of longer diffusion path, while increase of spore age increases the toxicity. These conidia, 5-10 days old, at a concentration of 1000 per 0.05 cc. of $CuSO_4$ solution are sensitive to 0.02 mg. Cu per liter, hence were used to detect toxic Cu in solution. $Ca(OH)_2$ and $CaSO_4$ cease to be toxic at 0.1 and 0.7 gr. per liter resp. $CaCO_3$ was non-toxic. In relation to atmospheric agencies it was found that no toxic Cu came into solution in distilled water standing on glass surfaces coated with Bordeaux mixture or copper-lime dust. Forced aeration for 5-9 days of the standing water resulted in only slightly toxic filtrates. The substitution of rain water together with aeration produced slightly more toxic filtrates, but rain water does not allow as good germination as distilled. Atmospheric agencies are therefore believed to be relatively unimportant. The filtrates from water in which *Sclerotinia* spores had germinated when placed on Bordeaux mixture or copper-lime dust invariably rendered the filtrate from the resulting suspension toxic, thus demonstrating a solvent excretion by the spores. Controls were non-toxic. Bordeaux mixture placed in collodion sacs which in turn were placed in distilled water did not give a diffusible copper, as the external water was non-toxic when the sacs were removed. If, however, spores were placed in the water in the presence of the Bordeaux-containing sacs, they did not germinate, thus indicating their solvent action. Spores placed at varying distances from a drop of dried Bordeaux mixture and connected therewith by a film of water were entirely inhibited from germinating up to 7.5 mm., beyond which point germination gradually increased. It is concluded that spore excretions are the chief agency in liberating Cu from insoluble copper protectants.—*S. E. A. McCallan.*

When gelatin wa... each concentration of NaCl, much less water ... or more water was lost by the skinless frogs. ... greater rate of osmosis due to gelatin than to ... accounted for by the rapid exchange of salt but ... gelatin between tissues and medium. The influenc... anesthesia, pithing, and addition of gelatin to the med... were evaluated upon both skinless and intact frogs. ... skinless frog and the pithed intact frog are under cer... ...ain conditions ideal osmometers. By comparing the rates ... of exchange which are due to osmotic pressure alone with ... the actual rates of exchange of normal intact frogs, ... those forces residing in the skin which ordinarily oppose ... the attraction of water by the osmotic pressure of the ... body fluids are evaluated.—*Author's summary.*

156. **ADOLPH, EDWARD F. Osmosis into frog skin, and the effects of isolation, of orientation, and of the blood's circulation.** *Amer. Jour. Physiol.* 96(3): 587-597.

1931.—Freshly isolated frog skin initially gains or loses water in proportion to the square root of the time elapsed after its immersion. In solutions of NaCl to which it is fully exposed, the gain or loss is linearly related to the concentration of the salt in the solution. If exposed only on its outer surface, the skin taken from pithed frogs likewise gains or loses in linear relation to the concentration of NaCl in the medium, at rates at least ½ of those found in the pithed intact frog. This fact refers the initial exchanges of water by the intact frog to the skin itself. Chlorides are exchanged by isolated skin at rapid rates which are in linear relation to the concentration of NaCl in the medium. The rate of the circulation bore no measurable relation to the concentration of the fluid being transported by it. In a few experiments in which the circulation was stopped altogether, the rates of osmosis into or out of intact frogs were the same as for normal intact frogs.—*Author's summary.*

157. **ADOLPH, EDWARD F. The initial rates of swelling of isolated muscle and their relation to the osmotic exchanges within the frog.** *Amer. Jour. Physiol.* 96(3): 598-612. 1931.—Gastrocnemii and upper-leg muscles were placed in various solutions of NaCl and gelatin. The initial exchanges of water were measured by frequent weighings, and occurred in proportion to the surface area of the muscle and to the square root of the duration of immersion. Osmosis at different concentrations of NaCl was linearly related to the concentration except in extreme dilutions, where osmosis was exceptionally rapid. When gelatin was present at any concentration of NaCl, the rate of osmosis inward was much reduced. The rates were slightly different at each concentration from those for skinless frogs. From the data for the initial rates of osmosis into each frog tissue that has been studied, osmotic constants was calculated, and the concentrations at which no exchanges of water occur are compared. The initial rates of diffusion of chloride into some of the same tissues are likewise compared by calculating diffusion coefficients. By means of numerical relations, the relative distributions of water among various tissues can be estimated from the initial rates of osmosis manifested upon immersion of these tissues in a common medium. The forces attracting and holding water in tissues are under certain conditions proportional to these initial rates of osmosis.—*Author's summary.*

158. **AMSON, KLAUS. Worauf beruht die irreziproke Permeabilität der Froschhaut?** *Pflüger's Arch. Ges. Physiol.* 225(4): 467-481. 4 fig. 1930.—The resting current of the skin of the frog is not connected with its one-way permeability since, while the electromotive forces fall off rapidly after the removal of the skin from the body, the one-way diffusion of methylene blue is maintained for a long time. Impermeability of the skin in the non-physiological direction may be found in a skin in which the E.M.F. has sunk to zero. The passage of an electrical current across a skin separating a pure Ringer solution from one containing methylene blue is without influence on the permeability with either direction of the current, even though high potentials are used. Influences which are liable to cause irreversible damage to the vital processes can make the skin permeable from without to methylene blue but still leave a definite difference between permeability in the physiological and the non-physiological direction. Among such may be mentioned heating to 45°; the action of chloroform, ether, alcohol, and NaF; and also spontaneous death. Putrefactive bacteria bring about a complete elimination of the one-way effect. It is suggested that one-way permeability is due to special structural arrangements which can be considerably damaged by killing agents but that only a destruction of the skin structures can bring about a complete elimination of the one-way permeability.—*D. J. Lloyd.*

159. **ANSELMINO, KARL JULIUS, und ELISABETH HOENIG. Weitere Untersuchungen über Permeabilität und Narkose.** *Pflüger's Arch. Ges. Physiol.* 225(1): 56-68. 2 fig. 1930.—Permeability in red blood corpuscles is checked by the addition of narcotics of the alcohol and urethane series. Their influence on the entrance of glycerin was studied by the hemolysis, and on the entrance of erythrite, pentoses, and hexoses by the hematocrite method. Since our knowledge of the structure of the blood corpuscle membrane allows one to separate different permeability mechanisms for the entrance of different substances, an attempt was made to analyze this checking of permeability observed in narcosis. With substances which enter through the pores of the blood corpuscle and whose permeation velocity becomes narcotized, it is assumed that retardation depends on the narrowing of the pore diameter by a layer adsorbed to the pore wall. In a 2nd class of substances whose velocity of permeation is slowed by narcosis, permeation is associated with chemical changes in the membrane structure or with additions to the membrane by adsorption. For an explanation of this process, the adsorption theory of narcosis, which formerly had been applied only to inner cell structures, is applied also to outer cell structures. In this way a broad contact is produced between the permeability and the adsorption theories of narcosis.—*Authors' summary (transl. by D. Ludwig).*

160. **CARO, L. de, e M. LAPORTA. Sul variare della tensione superficiale delle soluzioni proteiche in funzione del pH. [Effect of pH on surface tension of protein solutions.]** *Arch. di Sci. Biol.* 14(3): 264-292. 10 fig. 1930.—Gelatin, serum- and egg-albumin, in diluted or concentrated solutions, depress critically the surface tension of water at their isoelectric point, as pointed out by Bottazzi and collaborators. Changes of tensioactive power of the soluble proteins with pH are due essentially to unknown molecular changes. The molecular wt. of serumalbumin, as determined from static surface tension values, is 66,167. The monomolecular specific tensioactive power of serumalbumin, viz. tensioactive power at isoelectric point, was equal to 37.5×10^{-15} dyne/cm.—*A. Jappelli.*

161. **CHAPMAN, O. W., and J. H. BUCHANAN. The properties of starch with relation to time of formation of starch gels.** *Iowa State Coll. Jour. Sci.* 4(4): 441-450. 1930.—There is a fall-back in viscosity of starch pastes after the maximum value has been reached, and the gels formed from the paste exhibit syneresis, due to a rearrangement of gel aggregates which liberates some of the water enclosed by the original structure. Starch pastes of low concentration do not form as firmly bound gel aggregates as those of higher concentrations, and so are less viscous, and since their movement is less hampered, there is a greater degree of syneresis. Syneresis may be prevented or retarded by the addition of certain salts, due to the formation of firmer gel structures, which do not readily enter into rearrangements permitting the expression of water.—*Authors' summary.*

162. **COCA, ARTHUR F. On the dialyzability of proteins.** *Jour. Immunol.* 19(4): 405-410. 1930.—All of the 3 proteins of egg white studied are shown, with the use of specific antisera, to be dialysable through parchment, collodion, and animal membranes. A little less than 1% of the protein passed through the membrane in 5 days.—*A. F. Coca.*

163. **Du NOÜY, P. LECOMPTE. Équilibres superficiels des solutions colloidales.** 228p. 95 fig. Masson & Cie: Paris, 1929. Pr. 32 F.—This book is a French translation of the American edition, to which have been added results obtained since 1926. Full descriptions are given of the author's well known tensiometer for liquid-gas surfaces and of the later modification of the apparatus for liquid-liquid interfaces. Other chapters deal with the variations with time of the surface tensions of solutions of sodium oleate, serum, ovalbumin, etc. One chapter deals with the influence of these solutions on the crystallization of NaCl. The last 2 chapters deal with the colloidal explanation of solutions of proteins, serum, and plasma, and speculations regarding the forces at work in the formation of living cells. The book has a well-chosen bibliography and useful indices.—*E. F. Burton.*

164. **FISCHER, MARTIN H. The constitution of living matter.** *Trans. Kentucky Acad. Sci.* 3: 47-61, 2 fig. 1927/

the speed of the reaction rising with increase of length of the glycine chain. The α-naphthalenesulpho- derivative of hexaglycyl-glycine was split more slowly than the simple polypeptide. The same was true of the phenylisocyanate derivative of *dl*-norleucyl-*dl*-leucyl-glycine and glycyl-*dl*-norvalyl-*dl*-norvaline as compared with the corresponding free tripeptides. Erepsin at pH 7.8 attacked triglycyl-glycine and tetraglycyl-glycine but not the higher peptides; at pH 8.4 its action was somewhat more pronounced and extended to pentaglycyl-glycine. Trypsin-kinase at pH 7.8 attacked the halogenacyl compounds of the glycine polypeptides but not the corresponding simple polypeptides.—*E. McCoy.*

182. **ABDERHALDEN, EMIL, und FRITZ REICH. Weitere vergleichende Studien über den Einfluss von n-Alkali, Erepsin und Trypsin-Kinase auf polypeptidartige Verbindungen, an deren Aufbau β-Aminoisovaleriansäure beteiligt ist.** *Fermentforschung* 12(1): 20-41. 1930.—Erepsin extensively attacked several of the substances tested but trypsin left them unchanged with the exception of β-aminoisovaleryl-*dl*-leucyl-glycyl-*dl*-leucine and *dl*-leucyl-β-aminoisovaleryl-*dl*-leucyl-glycine. The corresponding halogenacyl compounds also resisted attack. It appeared that in all cases the β-aminoisovalerianic acid hindered the action of the amino- or carboxy-polypeptidase. It is possible that too much "foreign building stone" in the structure of the polypeptide resulted in a marked decrease in the affinity of the ferment for the substrate, or that the combination of the ferment and substrate was itself so stable that the existing pH did not suffice to bring about hydrolysis. *N*-alkali was extremely effective in bringing about hydrolysis of all but *dl*-leucyl-β-aminoisovalerianic acid.—*E. McCoy.*

183. **ABDERHALDEN, EMIL, und OTTO ZUMSTEIN. Über das Verhalten von Prolin enthaltenden Polypeptiden gegenüber dem Erepsin- und dem Trypsin-Kinase-Komplex.** *Fermentforschung* 12(1): 1-19. 1930.—Of the various dipeptides tested only glycyl-proline was attacked by erepsin; none were hydrolyzed by trypsin. Trypsin hydrolyzed *dl*-α-bromisocapronyl-*l*-proline but not *dl*-α-brompropionyl-*l*-proline nor *dl*-α-hydroxycapronyl-*l*-proline amide.—*E. McCoy.*

184. **BEST, C. H., and E. W. McHENRY. The inactivation of histamine.** *Jour. Physiol.* 70(4): 349-372. 1930.—The properties of the histamine-inactivating material under investigation are those characteristic of enzymes, and the name histaminase is suggested for the system or substance which is responsible for this loss of the physiological activity of histamine. In the dog, kidney and intestine are the richest sources of the enzyme; the histamine concentration in the lungs is not so high as that in certain other tissues. The histamine-histaminase reaction is inhibited by lack of O and by small amounts of cyanide. Under certain conditions the decrease in the iminazole content of the solutions was roughly parallel to the loss of histamine. This finding suggests that histaminase produces a rupture of the iminazole ring in the histamine molecule. A short study of the action of formaldehyde on histamine revealed certain differences in the mechanism of action of the aldehyde and of histaminase. Perfusion experiments were carried out using kidneys, liver, heart and hind limbs of the dog. The results showed that the isolated kidneys inactivate histamine much more rapidly than the other tissues investigated.

186. **CLEMENTI, A. Sulle condizioni in cui si manifesta l'attività antibatterica e antitossica della bile. I. Rallentamento della fermentazione lattica in presenza di sali biliari. [Conditions for the manifestation of the antibacterial and antitoxic activity of bile. I. Effect of bile salts on lactic fermentation.]** *Arch. di Sci. Biol.* 13(1/2): 211-220. 1929.—Bile salts retarded lactic fermentation and inhibited the conversion of caseinogen into casein. The decrease in pH, giving a strong acid reaction with litmus, precipitated bile salts and so indirectly retarded lactic fermentation.—*A. Jappelli.*

187. **CLEMENTI, A., e P. PRAMPOLINI. La concentrazione Idrogenionica optimum per l'attività enzimatica dell'asparaginasi animale. [Optimum pH for asparaginase.]** *Arch. di Sci. Biol.* 13(3-4): 443-465. 1929.—The pH most suitable for asparaginase from chicken's liver was 7.20-7.60, i.e., near the pH of tissues and blood, where the action of this enzyme usually occurs.—*A. Jappelli.*

188. **FLOREY, H. The relative amounts of lysozyme present in the tissues of some mammals.** *British Jour. Exp. Path.* 11: 251-261. 1930.—Titrations for lysozyme were given of various tissues of cat, rabbit, guinea-pig, rat, dog and man. Cat's tissues, with the exception of salivary gland, were extremely poor in lysozyme. The tissues of the guinea-pig were quite rich in the enzyme but the tears and saliva were almost completely free of it. The same applied to the rat. Rib cartilage was not specially rich in lysozyme. In general the spleen, kidneys, and lungs were richly supplied. In all spp., the content of extract of skeletal muscle in lysozyme was small or undetectable. Growing tissue did not seem to be specially well endowed with it for the testis had a low content. Brain had a very low content. Lymph gland had a moderate amount in all spp. Some results supported the idea of lysozyme being primarily an antibacterial agent; others were difficult to interpret on this basis.—*J. Bland.*

Sci.* 188(16): 1067-1069. 1929.—The enzyme which transforms allantoin into allantoic acid acts only when either Ca or $(NH_4)_2CO_3$ is present in the system. This enzyme is found in animal tissues (fishes, crustacea, echinoderms) and plants (*Soja, Phaseolus*).—*E. S. G. Barron.*

190. **KITAGAWA, MATSUNOSUKE.—On the signification of some auxosubstances in the urease reaction.** *Jour. Biochem.* 9(2): 347-352. 1928.—The urease free from the auxosubstance never lost its activity if the inhibitor was removed from the system. The presence of the inhibitor from any source caused a diminution of activity by the formation of an inactive complex. If, in such cases, the auxosubstances were added, they combined with the inhibitor in undissociable form to set free the urease in active form or to prevent the formation of an inactive complex. The urease activity was therefore determined by the relative amounts of auxosubstances and inhibitors in the reaction system.—*E. S. G. Barron.*

Zeitschr.* 220(1/3): 1-7. 1930.—The Na salt of iodo-acetic acid in concentrations down to 1000 prevented alcoholic fermentation by yeast and by preparations of zymase. No formation of hexosephosphates was observed in the experiments with yeast or zymase. Invertase, ptyalin and catalase were not affected.—*E. Lundsgaard.*

193. **LUNDSGAARD, EINAR. Über die Einwirkung der Monojodessigsäure auf den Spaltungs- und Oxydationsstoffwechsel.** *Biochem. Zeitschr.* 220(1/3): 8-18. 1930.—By treating yeast with iodo-acetic acid it was possible under definite conditions to reduce the fermentation to a minimum without affecting the respiration. Frogs were injected subcutaneously with the material in such a way that the formation of lactic acid was eliminated while the oxygen consumption remained normal.—*E. Lundsgaard.*

194. **MATTHES, K. The action of blood on acetylcholine.** *Jour. Physiol.* 70(4): 338-348. 1930.—To obtain a quantitative estimate of the rate of destruction of acetyl-

choline by blood or tissue extracts, the action was allowed to proceed for a definite time, and then brought to an end by the method used by Galehr and Plattner [1928]. The results indicated that the destruction of acetylcholine by blood is due to the action of an esterase, which is specifically inhibited by eserine, even in extreme dilutions, and also by fluorides.

195. MELLANBY, JOHN. Prothrombase—its preparation and properties. *Proc. Roy. Soc.* [*London*] *B* 107 (751): 271-285. 1930.—Prothrombase may be prepared from oxalated mammalian plasma by (a) precipitation at a reaction of pH 5.3, of the globulin complex from the plasma with 10 volumes of water; (b) extraction of the prothrombase from this complex by a dilute solution of calcium bicarbonate; and (c) precipitation of the prothrombase from the calcium bicarbonate solution by the addition of acid to a reaction of pH 5.3. The yield of prothrombase is about 40 mgrm. from 100 cc. of plasma. 1 mgrm. of the average prothrombase preparation when converted into thrombase coagulates 100 cc. of oxalate plasma in 20 sec. This fact in conjunction with the above explains the rapid coagulation of plasma when kinase (injured tissue) enters the blood stream. Prothrombase is a white amorphous powder which gives the characteristic reactions of acid meta protein. It is insoluble in water but freely soluble in dilute alkali. It is not dialysable through a collodion membrane, nor is it destroyed when an aqueous solution of it is heated to 100° C. for 5 min.; this latter procedure, however, diminished the rate at which it is converted into thrombase. Prothrombase may be activated by the addition to it of thrombokinase, but the rate of generation of thrombase is greatly accelerated by the presence of small quantities of Ca. The rate of activation is slow at the beginning of the reaction, but proceeds with a rapidly increasing velocity. The velocity of activation is modified by the reaction of the solution and by temp. Sr, Ba or Mg may replace Ca in the activation of prothrombase by thrombokinase. Sr is as effective as Ca in the activation process, but the efficiency of Ba or Mg is very small. With Ba or Mg, activation proceeds at a rate only slightly greater than that produced by thrombokinase alone.—*Author's summary.*

196. NAKAJIMA, KENZO. Refutation of the Schütz law and its analogous equations in the kinetics of enzymes. *Jour. Fac. Agric. Hokkaido Imp. Univ.* 28(3): 329-358. 1930.—From a critical study of many papers on the velocity of enzymatic reactions, where the so-called Schütz law has been considered valid, the author concludes that the Schütz equation can only be applied to the results obtained with dilute peptic solutions. The same criticism is made of the theoretical explanation of Arrhenius in support of the "Schütz law" and of Northrop's theory.—*E. S. G. Barron.*

Chem.* 22(5): 545-547. 1 fig. 1930.—Limed and bated hide pieces were plumped in acid or alkali and then neutralised. Such treatment did not alter the rate of solution of collagen by trypsin, but the trypsin acted on the remaining collagen to reduce its plumping, to lighten the colour and increase the mellowness of the leather produced from it, and to lessen its power of combining with vegetable tanning materials.—*R. O. Page.*

198. ROSENTHAL, OTTO. Die Vergärbarkeit verschiedener Zuckerarten durch Rattenleber. Ihre Abhängigkeit vom Ernährungszustand des Versuchstiers und von jahreszeitlichen Einflüssen. (Untersuchungen über Milchsäuregärung von Warmblütergeweben. III.) *Biochem. Zeitschr.* 277(4/6): 354-384. 1930.—Glycogen, sucrose, maltose, galactose, mannose, glucose, fructose, hexose-diphosphoric acid ester, hexose-monophosphoric acid ester, glycerinaldehyde, and dioxyacetone were studied. Only fructose and the 2 trioses were actively fermented. With mannose fermentation was barely perceptible, and no faster than with glucose. All the others were nearly or quite unaffected. Fructose and the trioses were actively fermented only if the animals had been fed, and even such livers varied considerably. In summer a considerable number of livers fermented dihydroxyacetone and a smaller number, fructose. In winter the power to ferment fructose and dihydroxyacetone was no greater in livers of fasting than in those of fed animals. Seasonal changes were less marked in fermentation of glycerinaldehyde, and it is probable that individual differences were due to differing amounts of a ferment-activator. Neither seasonal nor nutritional state was important in the dismutation of methylglyoxal, which was fermented four times faster than fructose or glycerinaldehyde.—*M. E. Collett.*

199. SCHÄFFNER, A. Enzyme und ihre Bedeutung zur Konstitutionsermittlung von Naturstoffen. *Fortschr. Chemie, Physik u. Physikal. Chemie, A* 20(7): 1-58. 1930.—Due to the work of Willstätter, Euler, their followers and others the knowledge of enzymes has been developed so that the use of enzymes in the analysis of natural substances is receiving recognition. This monograph is intended to give a summary of the results obtained in this direction and to point out further possibilities in the solution of problems of organic structure-analysis. The principles of enzymic methods and the purification of enzymes are presented. The specificity of enzyme action and thereby the usefulness of enzymes as reagents for certain groups or linkings are discussed, especially the enzymic breaking down of carbohydrates and proteins. The use of enzymes in the solution of structural problems of protein chemistry has led to distinct advances. The action of all proteolytic enzymes, however differently they may appear to act, is limited to hydrolysis of the peptide linking. The fractional breaking down of simple proteins, made possible by uniform enzyme preparations, permits of the examination of definite intermediate products of proteolysis. The enzymic splitting of nucleic acids made possible the recent discovery and identification by P. A. Levene as *d*-ribose of the sugar components of animal nucleic acid. The possibility of placing into distinct groups by the enzymic method the physiologically active compounds of unknown structure is pointed out.—*A. Schäffner* (*transl. by W. E. Thrun*).

200. SCHÖNFELD-REINER, R. Vergleichende Untersuchungen über die Spaltbarkeit von Peptonen und Polypeptiden durch die Fermente der Pankreasdrüse. *Fermentforschung* 12(1): 67-127. 6 fig. 1930.—Experiments were made upon the splitting of di- and tripeptides and peptone with fresh macerate of pancreas and with dried preparations from the soluble and insoluble portions of the macerate after acid coagulation, according to the method of Fodor. By kinetic measurements it was shown that the fresh macerate gives a linear curve in peptone splitting, whereas the precipitated macerate and the acid filtrate give parabolic curves. The acid coagulum (insoluble portion) is the enzyme-bearer for the splitting of the dipeptides and dipeptide complex of peptone. The filtrate (soluble portion) acts exclusively on the tripeptides and peptone. Later after autolysis, apparently autocatalytic, this soluble portion goes over to dipeptide splitting. On theoretical grounds therefore the conception that separate enzymes exist for each action is challenged.—*E. McCoy.*

201. SHERMAN, H. C., M. E. CALDWELL, and MILDRED ADAMS. Enzyme purification: further experiments with pancreatic amylase. *Jour. Biol. Chem.* 88(1): 295-304. 1930.—The new method for purification of pancreatic amylase involves adsorption by alumina gel and subsequent precipitation by alcohol and ether and yields dry solid preparations. The H-ion activities of the solutions at the different steps in the process had a decided influence upon the results obtained and were controlled and made reproducible by the presence of 0.01 M phosphate. It was found feasible, in testing the reaction of the aqueous glycerol and alcohol solutions sometimes used, to make electrometric measurements with the H electrode and saturated calomel cell. Solutions at pH 5.2 to 6.0, favored the adsorption of the amylase by alumina gel, and slightly alkaline solutions, about pH 7.3, favored the extraction of the amylase from the alumina gel by

which it had been adsorbed. This is in accord with the view that pancreatic amylase was of amphoteric nature. It was found possible to make use of glycerol in the early stages of the purification where it prevented or decreased the loss of activity of the amylase in solution and to omit its use in the later stages, after the adsorption, where it interfered with the precipitation of dry solid preparations. The active amylase could be effectively separated from glycerol by adsorption, but not by dialysis. The yields of purified pancreatic amylase obtained by this method were larger, and these enzyme preparations were slightly more active, than those obtained by the Sherman-Schlesinger method.—*Authors' summary.*

202. **[STEPPUN, O. A., and A. M. TIMOFEEVA.]** СТЕППУН, О. А., и А. М. ТИМОФЕЕВА. О причинах быстрого падения каталазного числа в растворах крови. **[Causes of the rapid fall of catalase index in blood solutions.]** [German summary.] Труды Научного Химико-фармацевтического Института (*Trans. Sci. Chem. Pharmaceut. Inst.* [*Moscow*]) 13: 5-12. 1926.—The rapid destruction of catalase from dilute blood solutions was not due to their destruction by blood proteases as Bach and Subkowa assumed. Blood solutions contain antitrypsin which inhibited proteolysis completely; and at dilution of one part of blood to 1000 of water that process was completely inhibited. The addition of trypsin did not bring about catalase activity in blood solutions; nor did the treatment of serum with chloroform (which increased serum autolysis), have any effect. In suspensions of blood corpuscles (the bearers of catalase in the blood) in physiological salt solution there occurred after the primary disappearance of catalase a regeneration of the catalase effect.—*Authors' summary (transl.).*

203. **[STEPPUN, O., and KSENIIA UTKINA-LIUBOVTSOVA.]** СТЕППУН, О., и КСЕНИЯ УТКИНА-ЛЮБОВЦОВА. Попытки установления животной уреазы. **[Experiments as to the existence of animal urease.]** [German summary.] Труды Научного Химико-фармацевтического Института (*Trans. Sci. Chem. Pharmaceut. Inst.* [*Moscow.*]) 13: 13-20. 1926.—The similarity in the distribution of enzymes in the plant and animal kingdoms suggested the question as to the existence of an animal urease. From investigations directed toward the detection of urease in cases of acidosis in diabetes or in fasting and also in cases in which acids are neutralized by ammonia, the author concluded that the normal liver of a rabbit, horse and dog contains minute quantities of urease; that urease could be more conveniently detected in the acid extract of the liver than in the ordinary expressed juice; that there were some grounds for believing that these small quantities of urease were derived from plants taken as food; and that the enzyme appeared to have no physiological significance, since in acidosis no mobilization for neutralizing the acids could be observed.—*Authors' summary (transl.).*

204. **[STEPPUN, O., and L. UTKIN-LIUBOVTSOV.]** СТЕППУН, О., и Л. УТКИН-ЛЮБОВЦОВ. О влиянии иода на аутолиз органов. **[The effect of iodine on the autolysis of organs.]** [German summary.] Труды Научного Химико-фармацевтического Института (*Trans. Sci. Chem. Pharmaceut. Inst.* [*Moscow*]) 13: 26-34. 1926.—In an earlier paper, the authors showed that yeast autolysis was increased by small quantities of iodine and inhibited by higher concentrations, and that the increased autolysis could not be ascribed to the inhibition of the activity of an antiprotease in Jobling's terminology, i.e., the saturation of the double bonds of unsaturated fatty acids. In this paper it is shown that the autolysis of organs is similarly promoted by small quantities of iodine and inhibited by larger quantities. This iodine effect appears to be specific for autolysis. The existence in the autolysate of only 1 pepsinase (in Rona's terminology) is questioned and the existence also of a cellular tryptase is assumed.—*Authors' summary (transl.).*

205. **[STEPPUN, O., and K. UTKINA-LIUBOVTSOVA.]** СТЕППУН, О., и К. УТКИНА-ЛЮБОВЦОВА. К вопросу о протеолитических ферментах печени. **[The proteolytic enzymes of the liver.]** [German summary.] Труды Научного Химико-фармацевтического Института (*Trans. Sci. Chem. Pharmaceut. Inst.* [*Moscow*]) 13: 35-46. 1926.—On theoretical grounds the existence of a typical tryptase in the organ cells is postulated. The detection of such a tryptase directly in the autolysate is difficult. Indirect methods of detection must be employed, such as a brief autolysis, in various buffer solutions, of an aging autolysate. Experiments were carried out to determine whether the autolytic capacity and the casein hydrolizing capacity of aged autolysate varied concurrently in various buffer solutions and during various periods of time. With 2 buffer solutions (pH 3 and pH 7 respectively) the following conclusions were obtained: (1) During the progress of autolysis the cleavage of the organism's own protein, and of casein, were not altered in the same way, in neutral (pH 7) and in acid pH 3.8. In the acid medium, proteolysis decreased regularly, while in neutral medium the decrease was abrupt, and almost invariably a phase of increased lysis was observed. This indicated that there is at least more than 1 ferment present.—*From authors' summary.*

208. **[UTKIN-LIUBOVTSOV, L. M.]** УТКИН-ЛЮБОВЦОВ, Л. М. Исследования над протеазами печени. **[Investigations on proteases of the liver.]** [German summary.] Труды Научного Химико-фармацевтического Института (*Trans. Sci. Chem. Pharmaceut. Inst.* [*Moscow*]) 13: 47-62. 1926.—Attempts were made to reenforce by direct experiments the indirect observations of the existence of various cell proteases [see also this issue Entry 204], and to determine the optimal conditions for their actions. Casein was used as a substrate; filtrates of the proteins of autolysates of organs coagulated at the isoelectric point were used as the enzyme solutions. When a finely ground organ was suspended in distilled water and placed in a buffer solution of pH 4.7-5.0, most of the protein was precipitated. The precipitate was removed by filtration. The enzyme was partitioned between precipitate and liquid, but sufficient for study remained in the liquid. When the filtrate was allowed to act as casein, 2 optima, at pH 5.2-5.4 and pH 3.0-3.4, were found; the minimum between them might perhaps correspond to the isoelectric zone of the casein. On edestin, its maximum activity was at pH 4.0; near pH 7, cleavage of edestin fell off sharply. The alkaline limit of action on casein was pH 7.5. The precipitate, treated with acetone, split casein in alkaline solution, the limit of activity in the alkaline was pH 7.5-7.6. It was concluded that there are, in liver, 3 proteolytic enzymes, acting on casein. In autolysis of the liver all 3 apparently played a rôle, and the curve showing the relation of autolysis to acidity is the resultant of their activity and of a series of other factors, among which the degree of dissociation of the liver protein is the most important.—*From author's summary.*

209. **ZAYKOWSKY, J., und P. ALEKSEJEFF. Die Katalase der Milch. I. Die Bestimmung der Milchkatalase mit $KMnO_4$-Titration.** *Fermentforschung* 12(1): 55-66. 1930.—The catalase of milk can be determined comparatively rapidly, conveniently, and with great accuracy by $KMnO_4$ titration. The method is: To 2 cc. of fresh milk add 98 cc. of water, 5 cc. of 0.3% H_2O_2; mix well and

leave 30 min. at room temp. At the same time prepare a control test using cooked milk. After 30 min. add to each mixture 5 cc. of 10% H_2SO_4 and titrate with 0.1 N $KMnO_4$. The difference between the reading for the fresh and cooked samples indicates the catalase content of the former and may be expressed as cc. $KMnO_4$, mgm. H_2O_2, or preferably as the catalase number of the milk in mgm. of O_2 per 10 cc. of milk.—*E. McCoy.*

210. **ADAMS, DOROTHY R., and PHYLLIS TOOKEY KERRIDGE. A note on the hydrogen ion concentration of the vitreous in eyes affected by naphthalene.** *Brit. Jour. Ophthalmol.* 14(8): 397-401. 1930.—Estimations of the pH of the vitreous of 1 or of both eyes were made on a series of 16 rabbits which had been dosed previously with naphthalene, and on 3 normals. The values for the pH of the vitreous from 3 normals and 13 naphthalinised rabbits were within the same range (7.20 and 7.48; av. for normals 7.28; av. for others 7.31). Samples of vitreous from each of a pair of eyes showed remarkably close agreement in pH; the range in pH of the vitreous at 18° C. is very close to that of blood at 38° C., although for a strict comparison the pH of vitreous would have to be determined at 38° C. In the remaining 3 naphthalinised animals values of 6.99, 7.66, and 7.99 were obtained without any obvious causative factor. The pH of the vitreous does not appear to change at any moment after the administration of naphthalene in such a way as to account for the development of cataract; neither is it affected by other intra-ocular changes such as retinal oedema or atrophy.

211. **AHLGREN, GUNNAR. Über die Einwirkung von Kohlensäure, Bikarbonat und H-Ionenkonzentration auf überlebende Organe und ihre Beeinflussbarkeit durch Pharmaka. Ein Beitrag zur Frage der Zusammensetzung der Serumsalzlösung.** *Skand. Arch. Physiol.* 59(1/2): 1-24. 11 fig. 1930.—In preventing pH changes in perfusion fluids, the author recommends (after Michaelis) the saturation of the serum salt solution with CO_2-O_2 mixtures. A nomogram showing the relation of pH to $NaHCO_3$ and CO_2 tension in (phosphate free) Tyrode solution has been constructed. By means of a $NaHCO_3$-CO_2 buffer system the pH of the serum salt solution as well as the intracellular pH is regulated in a physiological manner. The unique position of CO_2 as a pH regulator is emphasized. The effect of displacing the pH by changes in the $NaHCO_3$-CO_2 system in the serum salt solution was studied on rabbit intestines (according to Magnus), on rabbit hearts (with a modified Langendorff preparation), and on frog hearts (according to Amsler). On the rabbit intestines increase of bicarbonate at constant pCO_2 tension (44 mm. Hg) raises the tonus temporarily, increases the frequency, increases the regularity of contraction, and enlarges the amplitude. By varying the pCO_2 and keeping the bicarbonate constant corresponding effects can be noted. Occasionally one notices that an increase in pCO_2 (with lower pH) has a stimulating effect. Regular and strong movement is possible and independent of the relatively wide variation (certainly beyond physiological limits) in bicarbonate concentration, pCO_2, and pH. The effects of drugs on movements can, however, be modified. The stimulating action of acetylcholin on intestinal movements seems to be greater at pH 7.1 than at pH 7.7. The inhibition of adrenalin seems to be unchanged. Rabbit heart of pH 7.7 (1.1% $NaHCO_3$ and 10 mm. pCO_2) was affected positively inotropically when compared at pH 7.1 (pCO_2 34 mm.). The frog heart at pH 7.8 (0.1% $NaHCO_3$ and 7 mm. pCO_2) was affected positively inotropically, but occasionally negatively chronotropically, when compared at pH 7.1 (35 mm. pCO_2).—*Author's summary (transl. by W. E. Thrun).*

212. **ALBACH, WALTER. Zellenphysiologische Untersuchungen über vitale Protoplasmafärbung.** *Protoplasma* 5: 412-443. 1929.—The addition of K, Na, Ca, Mg, Al, and La greatly hasten the staining of living protoplasm by eosin, but in proportion to the acidity of the solution. Previous treatment in the salts causes no change in subsequent staining.—*W. Seifriz.*

213. **ANDO, KUNIO. Über die Hofmeistersche Ionenreihe bei der Aussalzung der hydrophilen Kolloide.** *Nagoya Jour. Med. Sci.* 2(2): 110-123. 1 fig. 1927.—These series are equally valid for the salting out of hemoglobin and egg white, either with or without careful control of pH, except in the presence of certain buffer salts (acetate, citrate, tartrate). The effect of valency is also unmistakably shown and is more pronounced as the pH is further from the isoelectric point, particularly in the acid range. The salting out of hydrophile colloids is due to simultaneous discharge and dehydration of micelles. There is a maximum susceptibility to alcohol at the isoelectric point because the charge on the micelles opposes the effect of alcohol, but not that of salts. There is a sharp increase in susceptibility to salts on both sides of the isoelectric point. Care must be used in determining the lyotropic position of bi- or poly-valent ions, because these have not only a dehydrating, but also a strong discharging effect.—*Author's summary (transl. by S. C. Brooks.)*

220. **BORSOOK, HENRY, and DOUGLAS A. MacFADYEN. The effect of isoelectric amino acids on the pH of a phosphate buffer solution. A contribution in support of the "Zwitter ion" hypothesis.** *Jour. Gen. Physiol.* 13(5): 509-527. 1930.—The relative merits of the classical conception and of the Zwitter Ion conception of the dissociation of amphoteric electrolytes are discussed, and the following data are presented which confirm the Zwitter Ion hypothesis of Bjerrum, and which are not in accord with the classical view. Amino acids in the isoelectric form resemble strong electrolytes in that they contribute to the ionic strength of the solution. The dielectric constants of aqueous solutions of amino acids, like those of solutions of strong electrolytes greater than 0.02 N., are considerably greater than that of pure water. The magnitude of the dissociation constants of substituted acetic acids and of glycine, are more easily accounted for with the Zwitter Ion than with the classical conception.—*Authors' summary.*

Excretion of the constituent ions of sulphur water.** *Lancet* 216(5520): 1244-1246. 1929.—A carefully conducted series of 4 experiments on 3 subjects in their usual health showed that drinking S water increases metabolism; stimulates the body ferments; causes a retention of Na; increases S metabolism by 50%; and causes a 70% skin excretion of Ca, Mg, Na, and K.—*D. J. Healy.*

223. **CHANOZ, M. Electrolyse des dissolutions de sulfate de cuivre cloisonnées par une membrane animale. Phénomènes observés au niveau de la cloison organique. Résultats expérimentaux.** *Compt. Rend. Soc. Biol.* 98(1): 42-44. 1928.—Diminution of current due to the increasing resistance of the membrane, polarisation, evolution of gas, and deposits on the membrane appeared progressively. The membrane appeared to be a non-uniform conductor, as the deposits were uneven. The origin of the gas is discussed, and the importance of the H and OH ions is stressed. The dilute solutions were most satisfactory.

224. **CHODAT, FERNAND. Importance de la nature des tampons protidiques dans l'activité des ferments solubles.** *Compt. Rend. Séances Soc. Phys. Hist. Nat. Genève* 47(1): 35-40. 1930.—Hitherto, various salt mixtures (phthalates, borates, phosphates, etc.) have been used invariably in in vitro experiments with controlled pH. To reproduce more closely the state of affairs in tissue, the use of protein buffers is suggested. The effect of pH on O evolution from H_2O_2 by catalase was followed in experiments in which (1) 1% gelatin, and (2) 1% commercial peptone (Siegfried) was present in the 1½% H_2O_2 solutions [500 cc. 2% gelatin was mixed with 500 cc. of 3% H_2O_2 at pH 7]. With peptone, the O evolution curve (cc. of O evolved in 8 min. per 25 cc. H_2O_2 substrate at varying pH values) was of the same type as when salt buffers are used; with gelatin buffer, the curves were anomalous, a sharp depression of apparent catalase activity being found around pH 4.4-4.5. This is thought to be due to adsorption of the catalase by the gelatine at the isoelectric point (pH 4.7) of the latter.

225. **COMEL, M. Variazione del pH delle soluzioni equilibrattici per azione del potere regolatore dei tessuti. [Variations of the pH values of buffer solutions as determined by the buffer power of tissues.]** *Atti R. Accad. Naz. Lincei Cl. Sci. Fis. Mat. e Nat.* 7(9): 772-778. 4 fig. 1928.—Tissue broth obtained by hashing muscles or liver of frogs, suspended in phosphate buffer solutions at different pH values exerted on them a considerable buffer action, changing the pH of the phosphate solutions (increasing it if the solutions were more acid than the tissue broth, decreasing it if the pH of the solutions was higher than that of tissues). The buffer action of the tissues is greater than that of M/30 phosphate buffer solutions and is different at different pH values.—*M. Comel.*

226. **COMEL, M. Sul potere equilibratore reciproco di due soluzioni regolatrici di fosfati. [The reciprocal buffer action of two phosphate buffer solutions.]** *Atti R. Accad. Naz. Lincei Cl. Sci. Fis. Mat. e Nat.* 7(11): 947-951. The buffer power of a M/30 phosphate solution at pH = 7.4 is higher than that of M/30 phosphate solutions with lower pH values, the difference of buffer power varying as the difference of pH values of the 2 solutions. These results as compared with similar ones obtained with tissue broth instead of the solution at pH = 7.4, lead to a discussion of the means by which the tissues exert their buffer action; systems of carbonates-carbonic acid, phosphates-phosphoric acid, and proteinate-acid protein come probably into play.—*M. Comel.*

227. **CURTIS, GEORGE M., and G. A. PACHECO. Experimental hypochloremia.** *Proc. Soc. Exp. Biol. & Med.* 26(9): 874-876. 1929.—Perfusion of distilled water through the peritoneal cavity at the rate of 500 cc. per hr. resulted in a pronounced lowering of blood chlorides. During perfusion there was continuous secretion of urine even to a moderate diuresis. CO_2 combining power of the plasma changed but little; non-protein N and urea of the blood decreased slightly. Muscular twitchings and convulsions developed; spasmodic contractions of the diaphragm took place. Death often occurred after prolonged perfusion.—*N. M. Payne.*

228. **DRZEWINA, ANNA, et GEORGES BOHN. Action de l'étain sur les oeufs et les larves d'oursin.** *Arch. Anat. Microsc.* 25: 576-586. 4 fig. 1929.—Sn was antagonistic to Ag. Eggs in Sn-Ag mixtures lived longer than in either metal alone. Sn in water caused sea urchin eggs (*Strongylocentrotus lividus*) to segment and exovate within 20-30 min. Eggs were divided farther than the 4 cell stage. Gastrulae could live a long time in Sn water, but never developed into normal plutei. Plutei placed in Sn water lost their arms, but when placed in normal sea water were able to regenerate new ones.—*N. M. Payne.*

229. **EPHRUSSI, BORIS, et LOUIS RAPKINE. Action des différents sels sur le Spirostomum.** *Protoplasma* 5: 35-40. 1928-1929.—*S. ambiguum* exists in 2 forms. One is exteremely rare and is characterized by a filamentous structure similar to that of *Stentor;* the other is alveolar. The filamentous structure is very unstable and is readily transformed into the alveolar form by a number of agents (pressure, temp., etc.). $CaCl_2$ greatly augments the instability of the system. $MgCl_2$ does not alter the condition apparently. KCl increases stability. $MnCl_2$ has the same effect as $CaCl_2$ but to a greater degree. When injected, $CaCl_2$, $BaCl_2$, and $MgCl_2$ cause severe disruption;

NaCl and KCl produce little change except slight liquefaction. Injected HCl causes local coagulation. Ether produces liquefaction.—*W. Seifriz.*

230. FINLEY, HAROLD EUGENE. Toleration of fresh water protozoa to increased salinity. *Ecology* 11(2): 337-347. 1 pl., 1 fig. 1930.—Fifty spp. of protozoa, in mixed cultures, were studied for toleration of natural and artificial sea water in various concentrations. Three methods were used: direct transfer, recovery from cysts, and gradually increased salinity. There was marked variation in toleration even in closely related forms. The % tolerated was usually greater when gradually increased than in direct transfers. Four sp. lived when transferred directly to sea water: *Bodo uncinatus* (Kent) Klebs, *Colpoda aspera* Kahl, *Pleuromonas jaculans* Perty, and *Uronema marina* Duj. The first 2 were also recovered from 100% artificial sea water inoculated with unsterilized hay. Excystment did not take place in greater salinity than that tolerated in direct transfer of active individuals. Presence of debris and scum in transfers increased % of salt tolerated. *Amoeba verrucosa* Ehrbg. was the only form which lost its contractile vacuole in high salinity. The rate of pulsations became slower in other forms as the salinity increased. Visibility of motor organelles increased with higher salinities. A method of chloride determination adapted to the experiments is also described.—*G. Alexander.*

231. GELLHORN, E. SCN-contracture in skeletal muscle. Further studies in permeability of muscle. *Amer. Jour. Physiol.* 96(1): 203-213. 1931.—If a Ringer's solution, containing NaSCN in a concentration which is below the threshold for direct contracture, is allowed to bathe the frog sartorius muscle for a definite time, and is then replaced by Ringer's solution, a contracture takes place which is called indirect contracture because of its occurrence in pure Ringer's solution. This indirect contracture can be obtained also by application of other SCN salts such as $Ca(SCN)_2$ and NH_4SCN. This and the observed low value of the isometric tension show that the indirect contracture is a SCN-contracture. The strength of the indirect SCN-contracture depends chiefly upon the composition of the 2nd solution which is substituted for SCN-Ringer's solution. It is much greater in NaCl than in Ringer's solution, and by the addition of small amounts of Ca, Sr, or Mg or still lower concentrations of heavy metals such as Cu, Co, and Fe, indirect contracture can be suppressed completely. It increases with decreasing osmotic pressure and increasing pH. It is favored by stimulation of the muscle with condensor discharges. The assumption that the strength of indirect contracture is determined by the velocity with which NaSCN leaves the muscle cell and therefore by the permeability of the muscle easily explains these facts because ions increase and decrease indirect contracture in the same sense as they influence permeability. There is but 1 exception: $BaCl_2$ if added to the 2nd solution increases the strength of indirect contracture.—*Author's summary.*

232. GELLHORN, E. Further experiments on direct and indirect SCN-contracture. The dependence of ion antagonism on permeability. *Amer. Jour. Physiol.* 96 (2): 477-483. 1931.—The strength of the indirect SCN-contracture depends very much upon the time during which the solution containing NaSCN is in contact with the muscle. The indirect contracture is also influenced by changing the composition of the solution containing NaSCN. But in general alterations in the 2nd solution for which the NaSCN solution is exchanged influence the muscle more profoundly. There is a remarkable quantitative difference in the susceptibility of muscle to the same ions which seems to be the expression of a more general rule: Ion effects depend to great extent upon the permeability of the cell. There is a close parallelism between KCl-contracture and direct SCN-contracture with respect to the influence of ions, but with the exception that Ba acts upon the KCl-contracture as the other alkali earths do, while it has just the opposite effect upon both direct and indirect NaSCN-contracture. The direct and the indirect SCN-contracture in the tissues of vertebrates can be used to demonstrate the laws of permeability.—*Author's summary.*

233. GOYENA, JUAN RAÚL. El cloro en la regulación del equilibrio ácido-base. [Chloride and acid base equilibrium.] *Semana Med.* 35(1816): 1162-1165. 1928.—Intravenous injection of NaCl solution (50 parts per 1000) produce a marked diminution of the reserve alkalinity in the blood of dogs and hyperchloruremia, while its administration through the mouth (5 parts per 50 parts H_2O) produces a slight increase in the reserve alkalinity of the blood and hypochloruremia.—*V. G. Lava.*

234. HAYASHI, TEIJIRO. The changes in sea water and their influences upon marine animals. II. The influences of natural salts upon the germ cells of sea-urchin. [With Japanese summary.] *Trans. Sapporo Nat. Hist. Soc.* 11(2): 101-113. 2 fig. 1930.—The influence of chlorides of Na, K, Ca, and Mg upon germ cells of *Strongylocentrotus nudus* was examined. The unfertilized sea-urchin eggs did not form the parthenogenetic membrane in the isotonic solutions of these neutral salts. In the isotonic solutions of chlorides of Na, K, and Mg the unfertilized eggs kept their susceptibility to fertilization more than 12 hrs. The toxic order of these salts for the unfertilized sea-urchin eggs is as follows; Ca, Mg, K, Na. The fertilization membrane is permeable to the cations and accordingly the fertilized eggs are more susceptible to these cations than the unfertilized eggs. There is an antagonism among neutral salts against the toxic actions upon the eggs.—*Author's summary.*

235. HEINSHEIMER, S. Über den Einfluss der Azidose und der Alkalose auf das weisse Blutbild. *Frankfurter Zeitschr. Path.* 40(1/3): 277-287. 1930.—Experiments on 17 rabbits and 2 human subjects are tabulated. Marked acidosis of the blood could be produced by inhalation of CO_2, and intravenous injection of weak HCl, and glutamic and fumaric acids. Marked alkalosis was also produced by intravenous injection of soda. Inhalation of CO_2 reduced the pH of the blood in human subjects from 7.37 to 7.25-7.29; in the rabbit, from 7.32 to 7.06, and acid injection from 7.28 to 6.07-6.42. Soda injection raised it from 7.32 to 8.52. These disturbances of the acid-base equilibrium produced changes in the peripheral blood picture, acidosis producing an increase in myelocytes, alkalosis in lymphocytes. These changes are attributed to effects of different kinds on the sympathetic and parasympathetic systems, respectively. The absolute leukocyte values were not affected by disturbance of the acid-base equilibrium of the blood.—*Author summary (transl.).*

236. HELFF, O. M. Toxic and antagonistic properties of Na, K, Mg and Ca ions on duration of life of Cambarus clarkii. *Proc. Soc. Exp. Biol. & Med.* 26(9): 797-798. 1929.—Preliminary paper.

237. HENSAY, JOSEFINE. Der Einfluss verschiedener Puffergemische auf die Löslichkeit von Eiweisskörpern des lebensfrischen, ermüdeten, absterbenden und starren Muskels. *Pflüger's Arch. Ges. Physiol.* 224(1): 44-61. 1930.—Solubility of muscle proteins was greater in K than in Na solutions. It was greater in phosphate than in acetate. In all buffer mixtures the point of least solubility was pH 5. Increase in concentration in both phosphate and acetate mixtures was proportional to the absolute amount of muscle protein going into solution. Denaturation of protein occurs in extraction. In acetate mixture at pH 4 there was a sudden increase in protein solubility; in phosphate solution a decrease. This same point of change in solubility holds also for fatigued muscle. In muscle after death rigor and chloroform rigor the proteins show the same decrease in solubility in phosphate solutions, but do not show a change in solubility or show a decrease in acetate mixtures. Muscle after treatment with liquid air showed no point of solubility at pH 4 in acetate mixtures, but showed a decrease in buffer mixtures.—*From author summary (transl.).*

238. HESS, OLGA T. The effects of pure solutions of sodium, potassium, and calcium chlorides on the oxygen

consumption of Planaria dorotocephala. *Physiol. Zool.* 3(1): 9-47. 2 fig. 1930.—Changes of O consumption of *P. dorotocephala* were determined by the Winkler method and with Barcroft differential manometer in distilled water and in pure salt solutions of varying concentrations. Temp. and pH were kept constant. Respiration in distilled water remains normal until death changes begin, and shows a slight tendency toward depression during the first few hrs. of exposure; duration of life is dependent on how frequently the medium is renewed. In 0.1 M, 0.04 M, and 0.02 M NaCl the respiration after a period of muscular activity approaches the normal level and rises again with beginning disintegration. In KCl solutions (0.04 M-0.004 M) O consumption rises and continues to increase during paralysis. *P. dorotocephala* can live over a mo. in 0.02 M-0.002 M $CaCl_2$, in high concentrations a decrease in respiration was followed by a return to normal with every renewal of the medium. A slight difference in the rate of body wt. loss was observed in $CaCl_2$ as compared to well water. The high tolerance to $CaCl_2$ may be due to a high proportion of this salt in natural environment of the worms. The upper limit of the osmotic range for the 3 salts used decreases in the order $CaCl_2$, NaCl, KCl, which corresponds to the ratio of these cations in natural waters: 49: 3: 1.—*Author (courtesy Wistar Bibl. Serv.)*.

239. **HÖBER, RUDOLPH. Über die Bindung des Kaliums im Muskel. Erwiderung auf die VII. Mitteilung von Neuschlosz: Über die Bedeutung der Kaliumionen für den Muskeltonus.** *Pflüger's Arch. Ges. Physiol.* 221(4): 478-485. 1929.—A repetition of Neuschlosz's latest experiments on the leaching of K ion from frog muscles failed to confirm his view that the repeated use of small quantities of solvent (Raab's technique) leads to erroneous results. Agitation aids extraction from [*Rana*] *temporia* muscles, but lessens it in the case of more active *esculenta*, which produces more acid. Increase of acid diffusion lessens the destructive effect of acid accumulation on the membranes retarding diffusion of K^+. Increased alkalinity of the medium decreases the K^+ extraction, which at pH 8.2-8.57 is increased by agitation and fine division of (*esculenta*) muscle. There is no evidence for the binding of K in non-diffusible form by muscle proteins.—*F. F. Heyroth.*

240. **JENDRASSIK, L., und A. CZIKE. Zum Chemismus der vegetativen Reizung. Weitere Versuche über die angebliche Rolle von Ionen.** *Biochem. Zeitschr.* 193(4/6): 285-299. 1928.—The authors compared the actions of (1) pilocarpine and K and (2) adrenaline and Ca on a variety of isolated plain muscles. The change from Tyrode's fluid lacking KCl to normal Tyrode's fluid always inhibits plain muscle, whereas pilocarpine causes excitation. In many cases Ca excess and adrenaline produce opposing effects. These results are contrary to the theory of Zondek that there is a regular parallel between the actions of pilocarpine and K, and between those of adrenaline and Ca.—*A. J. Clark.*

241. **JOHNSON, WILLIS HUGH. The reactions of Paramecium to solutions of known hydrogen ion concentration.** *Biol. Bull. Marine Biol. Lab.* [*Woods Hole*] 57(4): 199-224. 1929.—The pH was determined by the colorimetric method but checked with a Youden's potentiometer. Both organic and inorganic acids were used to acidify water from several sources. Only paramecia (*P. caudatum*) from alkaline cultures responded positively to acidified solutions in these experiments. Such paramecia react positively at all pH values lower than their culture to pH 5.0 inclusive when the H-ion concentration is produced by inorganic acids, in all waters used except one. The organic acids elicit similar responses except that tannic and pyrogallic acids are toxic in the lower ranges studied. Paramecia react to acidified water from which all carbonates have been removed indicating that they react to the H ions and not to CO_2. The nature of their reaction is the same upon coming into contact with strong acids (more acid than pH 5.0) and upon coming into contact with culture medium after they are already in the acid solution (less acid than pH 5.0). Paramecia are not able to live in concentrations lower than pH 5.0. This indicates that their behavior in reacting to acids is protective.—*W. H. Johnson.*

242. **JUNKER, HERMANN. Die Wirkung extremer Potenzverdünnungen auf Organismen.** *Pflüger's Arch. Ges. Physiol.* 219(5/6): 647-672. 21 fig. 1928.—Renewed investigations were made of the effects of dilutions ranging from $1:10^1$ to $1:10^{27}$ of the most varied substances viz., cocaine, Na-desoxycholate, nonylic acid, octyl alcohol, K-oleate, HCl, acetic acid, urea, $MgSO_4$, $CuSO_4$, and rubio (a vitamin preparation) on the rate of multiplication of *Paramecium* and other biological objects. No limiting value was found within the series of dilutions studied and it is almost certain that biological effects occur even in higher dilutions than $1:10^{27}$. Expressed graphically the results give curves of a very definite and uniform type for all the substances investigated (a deep, broad minimum at about $1:10^{13}$, a rather less marked minimum at about $1:10^{24}$, and a downward kink at $1:10^{27}$). Up to a concentration of about $1:10^{27}$ irregularities appear in the curves owing to the specific effects of the substances within this part of the range, but in the higher dilutions these irregularities cease and the curves for all the substances tested are similar, i.e., non-specific. Two or more such series working simultaneously act independently of one another. This result can also be deduced from Kolisko's data for wheat.—*H. Junker (transl. by H. Sandon).*

243. **KOLTHOFF, I. M. The confusion in the expression of the so-called "hydrogen ion concentration" of a solution and a review of Brönsted's conception of acidity and basicity.** *Rec. Trav. Chim. Pays-Bas et Belgique* 49(4): 401-414. 1930.—The terminology of the expression of the acidity of a solution should be rationalized. It is proposed to define (H^+) and pH by their actual significance and to express the corresponding values of the activity and activity exponent by (aH^+) and *pa*H. Values derived on the basis of Sörensen's original work should be indicated by the Sörensen value (sH^+) and the Sörensen exponent *ps*H. The acidity of an aqueous solution should be expressed by the hydronium ion and not by the H ion concentration, because no free protons occur to any measurable extent. Some consequences of Brönsted's conception of acidity and basicity have been given.—*I. M. Kolthoff.*

244. **KOLTHOFF, I. M., und J. J. VLEESCHOEWER. Eine Vervollständigung der Reihe Pufferlösungen im alkalischen Gebiet.** *Biochem. Zeitschr.* 189(1/3): 191-193. 1927.—Measurements of buffer solutions were made with the quinhydrone electrode standardized against an H^+ electrode. Proportions of a buffer of 0.1 M Na_2HPO_4 and 0.1 N NaOH are given for making buffer solutions of pH 11-12 in steps of a 0.2 pH. Proportions of 0.05 M Na_2CO_3 and $Na_2B_4O_7$ to make solutions of pH 9.2-11 are given, and also directions for making buffer solutions from 0.1 M KH_2PO_4 and .05 M $Na_2B_4O_7$ to produce solutions of pH 6.0-9.2.—*N. M. Payne.*

245. **KONDO, KINSUKE, and TSUNETOMO HYASHI. The influence of salts on the iso-electric behavior of the protein.** *Bull. Chem. Soc. Japan* 3(6): 146-151. 1928.—Metallic chlorides added to solutions of rice glutelin in an acetate buffer, shift in the direction of increased acidity the pH at which the protein shows its minimum degree of ionisation. On account of their ionising effect small concentrations of metallic cations diminish the amount of protein precipitated at its true iso-electric point; in larger concentration the cation increases the amount of protein precipitated by forming an insoluble complex; while in the highest concentration precipitation is again diminished owing to the formation of soluble complexes. The magnitude of these effects is determined by both the valency and the nature of the cation employed.—*T. R. Parsons.*

Gleichgewichte zwischen CO_2 und Phosphatlosungen. (Ein Beitrag zur Theorie der CO_2-Bindungskurve.) *Biochem. Zeitschr.* 215(1/3): 137-151. 1929.—In studying the equilibrium between CO_2 and solutions of phosphates, a comparison was made between phosphate solutions of equal concentration under conditions of varied pH, as well as between solutions in which the relationship between primary and secondary phosphates was constant but which had a varied phosphate concentration. A variable change of volume % CO_2 at different CO_2 tensions is found with a variable pH. The change with phosphate concentration is less pronounced. The results obtained are comparable to those obtained earlier when the CO_2 binding capacity of urine was investigated. The effect which the dilution of blood, or the addition of strong and weak acids, has upon its CO_2 binding capacity and the relationship of hydremia to acidosis is discussed.—*J. M. Johlin.*

248. MANKIN, WINIFRED R. Estimation of total chloride in tissue. *Med. Jour. Australia* 2(11): 358-367. 1 fig. 1929.—About 1 gm. of tissue is weighed by difference in a corked glass test tube. It is digested with 5 cc. of HNO_3 in the presence of excess 0.01 N $AgNO_3$ on a water bath. When digestion is complete and the volume of solution has been evaporated to about 3 cc., 6 cc. of distilled water and 3 drops of ferric alum are added. The excess $AgNO_3$ is then titrated with 0.01 N thiocyanate. A duplicate which is not titrated to completion is stood beside the above to facilitate observation of the end point. The chloride content of egg white is usually higher than that of egg yolk from the same egg. The content varies considerably in whites of eggs laid by different hens. The same applied in the case of yolks. Using the figures obtained for chloride concentration, it has been calculated that it is possible for 4.03% of the intensity of a beam of homogeneous x-rays to be absorbed while travelling through an egg.—*W. R. Mankin.*

249. MANKIN, WINIFRED R. Concerning the source of calcium required by the developing chick embryo. *Med. Jour. Australia* 2(26): 916-919. 1929.—A method dealing with the accurate estimation of Ca in tissue is described. The Ca content of the yolks of unincubated eggs is about 0.10% and that of egg white about 0.01%, so that the total Ca content of an unincubated egg approximates 23 mgm. The Ca content of a newly hatched chick is about 105 mgm. The average water content of yolk is 49%. The average water content of white is 89%. The average water content of a 4-day embryo is 95%. The average water content of a newly hatched chick is 69%. The presence of Ca in the yolk of the incubated and developing egg in concentration similar to and greater than that of the non-incubating egg is indicated, as is also the presence of Ca and P in the allantoic fluid.—*Author's summary.*

250. MAST, S. O. Effect of salts, hydrogen-ion concentration, and pure water on length of life in Amoeba proteus. *Physiol. Zool.* 4(1): 58-71. 1931.—*Amoeba proteus* functions normally in chemically pure water, and some specimens live in it 16 days without food. If salt is added, length of life is prolonged a few days. The relative effect of different salts depends upon the concentration. In N/1000 solutions the order of the length of life is $Na > Mg > Ca > K > NH_4$, but in stronger solutions it is greater for Ca than for Na salts. There is very little difference in the effect on the length of life of the following anions: SO_4, NO_3, Cl, PO_4. The anion $C_2H_3O_2$ is relatively more toxic than the others mentioned. Length of life in strong solutions is much greater for mixed salts than for single salts. *A. proteus* lives several days in solutions in which the pH ranges from 4 to 8, and there is no marked difference in the length of life over this range. There is probably a double optimum, one at about pH 6.8 and another at about pH 4.8. Beyond pH 4 and 8 the length of life decreases very rapidly. The effect of pH depends upon the salt concentration. The stronger the salt solution, the more acid the optimum and the less the effect of the H ions. Fission is not specifically dependent upon the composition of the solution in which the amoebae live. It occurs in pure water and in solutions of various chemicals.—*Author (courtesy Wistar Bibl. Serv.).*

251. MAUME, L., et J. DULAC. Variation du pouvoir antitoxique en fonction de l'ionisation. *Compt. Rend. Acad. Sci. [Paris]* 184(20): 1194-1196. 1927.—Previous studies have shown that the minimum toxicity of a mixture of 2 salts (NaCl and $CaCl_2$) is, within certain limits, dependent on their proportions and not affected by concordant change in concentration. In this new series of experiments, it is shown that as the value of K (the concentration constant) increases from 1, toxicity becomes manifest; as K becomes less than 1, toxicity decreases. The effect seems due to ionization changes.

252. MERKER, E. Birgt die Gebundenheit von gewissen Seetieren an eine bestimmte Salzdichte des Wohnwassers ein Atmungsproblem? *Zool. Jahrb. Abt. Allgem. Zool. u. Physiol.* 44(4): 483-522. 1 fig. 1928.—*Neomysis vulgaris* can live only a few days in fresh water. During the survival period the animals make violent movements of the gills that suggest that death is due to an interference with respiration. Aeration of the fresh water with pure O does not prolong the survival period, so that the respiratory difficulty appears to be concerned with the elimination of CO_2. When in fresh water the animals are killed by a smaller rise of temp. than when in their natural habitat of brackish water of 0.5% salt concentration. In 1 unconfirmed experiment the animals failed to survive in a solution of common salt of this concentration. In 10% salt solution they become opaque and immobile in 15 min., but many of them recover on being replaced in brackish water. The temporary changes of salt concentration occurring in a tidal estuary probably do not harm the animals, but the need of a certain concentration of salt for the normal respiratory process is a factor that limits their migration into fresh water.—*T. R. Parsons.*

253. MICHAELIS, L. Diethylbarbiturate buffer. *Jour. Biol. Chem.* 87(1): 33-35. 1930.—Veronal is recommended as a buffer covering a range from pH 6.8 to pH 9.6. It replaces not only the borate buffer which is undesirable in many cases but also duplicates a part of the phosphate buffer range, especially around the physiologically important pH 7.4.—*Author's summary.*

254. MILLER, EDGAR GRIM, JR. The effect of bicarbonate ions on the swelling of gelatin. *Biochem. Jour.* 23(5): 876-879. 1 fig. 1929.—The effect of varying bicarbonate concentration and pH on gelatin swelling was studied over a limited range and found to be of the same order of magnitude as the corresponding effect of the chloride ion.—*E. B. Carmichael.*

255. MISSKE, BRUNO. Über die Wirkung der Kationenverschiebung in der Ringerlösung auf den peripheren Nerven. *Biochem. Zeitschr.* 219(4/6): 320-329. 1930.—The author devised a coördinate system of three axes, on which he plotted varying concentrations of KCl, $CaCl_2$, and NaCl. In all cases the resulting solution was isotonic, but in some cases lacked or was low in Ca, in others was low in Na or K. Paralysis of a nerve was brought about more quickly by high KCl values than by corresponding increases in $CaCl_2$, which were unable to reverse the effects of high KCl completely. High NaCl produced a characteristic sudden change in the nerve. There is both synergy and antagonism between the 3 ions. The total effect of the solution is due to all 3. There is antagonism not only between K and Ca, but also between Na and K and between Na and Ca.—*N. M. Payne.*

256. MISSKE, BRUNO. Über die Wirkung der Kationenverschiebung in der Ringerlösung auf die quergestreifte Muskulatur. *Biochem. Zeitschr.* 219(4/6): 330-334. 1930.—The author devised a diagram with coordinates in 3 axes. From this diagram he calculated varying concentrations of $CaCl_2$ and NaCl that would keep the solution isotonic but unbalanced. On striated muscle K and Ca are not as much antagonistic as synergic. Na may act as a synergist to K and Ca, and also an antagonist. High K did not increase muscle contraction; in fact, a solution of 75% NaCl and 25% $CaCl_2$ produced

a muscle contraction like that attributed to high K.—*N. M. Payne.*

Lettere Arti* 88(7): 715-724. 1928-1929.—The pH of the sap of silk-worm eggs as measured with a quinhydrone electrode increases in the 1st period of the experiment depending on the reactions between the sap and the quinhydrone. After a few min. the pH is stabilized. During the incubation of the eggs the pH increases from 6.70 to 6.86.—*M. Tirelli.*

258. **PAGE, IRVINE H. The toxicity of monovalent and divalent cations for sea urchin eggs.** *Biol. Bull. Marine Biol. Lab.* [*Woods Hole*] 57(6): 449-457. 5 fig. 1929.—The toxicity of the following cations, used as chlorides, for the *Arbacia* egg was: $Li > Na > Ca$, $Mg > K > Rb > Cs$. It has been suggested that the term "toxicity" is applied to a miscellany of the most heterogeneous reactants in protoplasm; hence as an entity its prediction and formulation in our present state of knowledge are not probable.—*I. H. Page.*

259. **PASTEELS, J. Essai d'analyse de la physiologie de l'oeuf de pholade (Barnea candida). Effets des solutions salines non balancées. Note préliminaire.** *Acad. Roy. Belgique Bull. Cl. Sci.* 15(5): 421-448. 1 pl., 6 fig. 1929.—The use of unbalanced saline solutions is an efficient method of analysis of the physiology of the fertilized egg. Not only does the unfertilized egg, except for rare monasters, refuse to undergo parthenogenesis, but the fertilized egg shows no acceleration in any process, neither in karyokinesis, nor in cytokinesis. All that one is successful in doing is to impede one or another mechanism, and thus institute an abnormal situation favorable for analysis. The fertilization of the egg of *Pholas* is accompanied by no perceptible cortical alterations or transitory contraction. An artificial swelling of the membrane can be produced by Ca^{++} and Na^{+} ions, depending upon the stage. This is due to a cortical cytolysis, for which Ca^{++} and Na^{+} are synergetic, while K^{+} and especially Mg^{++} are antagonistic. The properties of the cortex appear slightly different than those of the endoplasm: The permeability and the resistance of the cortex are variable with the stage. The sensitivity of the cytolytic ions increases with the entrance of the unfertilized egg upon maturation, and still more with fertilization. Before segmentation, the constitution of the cortex is further altered. Fertilization is largely tributary to the saline constitution of the center. Na^{+} and Ca^{++} ions are indispensable. Centers rich in Ca^{++} and Mg^{++} and diluted sea water produce a depolarization of the movements of maturation in slightly different degrees in unfertilized and fertilized eggs. Unbalanced solutions impede the migration of the pronuclei and thus permit the verification that the center producing the diplosome rests in the ♂ pronucleus. Under the same conditions, a sufficient delay produces a ♀ oocenter, incapable of becoming dicentric. The more precocious arrest of cytokinesis in certain blastomeres in relation to their cellular volume is small; the hindrance of the mitotic mechanism by ionic unbalance is more rapid.—*Author's summary (transl. by P. L. Risley).*

260. **PETERS, JOHN P. Acid-base equilibrium and salt and water exchange.** *Yale Jour. Biol. & Med.* 2(3): 183-221. 8 fig. 1930.—A comprehensive discussion of theory.

261. **POPOW, N. A., und A. A. KUDRJAWZEW. Zur Frage der Lebensdauer der einzelnen Teile des Froschherzens in Flüssigkeiten von verschiedener Ionenzusammensetzung.** *Arch. Exp. Pathol. u. Pharmakol.* 147(4/6): 331-338. 1 fig. 1930.—In normal Ringer's fluid the bulbus arteriosus had the longest life, i.e., it maintained its characteristic rhythm for the greatest length of time after removal from the frog. In fluids without Ca the sinus venosus remained alive the longest. Ca appeared to have more effect on the heterotropic automatism of the heart than on the nomotropic automatism.—*N. M. Payne.*

262. **SALVESEN, H. A. Die Serumchloride und die Neutralitätsregulierung.** *Zeitschr. Klin. Med.* 109(3/4): 102-311. 1928. *Also in: Norsk. Mag. Laegevidensk.* 88 (11/12): 1124-1130. 1927.—In clinical cases of uremic acidosis organic acids are retained in the blood. Chloride ion disappears from the serum and the corresponding amount of base is available for neutralizing this additional acid. The same is true in diabetic acidosis. Greatly reduced chloride is considered a bad symptom in nephritis.—*R. S. Anderson.*

263. **SATO, JUNITI. Nouvelles recherches biologiques sur le manganèse.** *Arch. Internat. Pharmacodyn. et Thérap.* 36(1): 49-72. 1929.—A comparative study of the toxicity of bi- and tri-valent Mn compounds was made by determining the effects of intravenous dosages in rabbits. The compounds were injected as 1% solutions in isotonic NaCl. Bivalent Mn produces symptoms in dosages of 3 mgm. per kgm.; 7-10 mgm. per kgm. is fatal. Trivalent Mn produces symptoms in dosages of 7 mgm. per kgm., intoxication with 15-20 mgm. per kgm., and death occurs 10 or more hrs. after dosages of 25 mgm. per kgm. The depressant effect of bivalent Mn on the blood pressure is 6 times greater than that of trivalent compounds. The respiration is stimulated with small dosages up to a maximum. Beyond this maximum depression occurs. Mn probably acts as a catalyser of oxidations. The gas exchange following the subcutaneous injection of $MnCl_2$ is altered in proportion to the dosage administered. The O_2 utilized and CO_2 output is increased with dosages of 2 mgm. per kgm. The increase in O_2 intake increased 3.9% at the ½ hr. and 7.6% after 5 hrs. The CO_2 output increased 21.8% at the ½ hr. and 2.5% after 5 hrs. Dosages of 10 mgm. per kgm. decrease both the O_2 intake and CO_2 output. The degree of change was approximately 30%. The depressant effect was evident after 30 min., became maximal at the 5th hr., but was evident at the 8th hr. The toxic effect of Mn on metabolism is comparable to that of Fe.—*O. W. Barlow.*

264. **SCHILOW, NIKOLAI. Notiz über den vermutlichen Chemismus der physiologischen Wirkung hypertonischer Lösungen.** *Biochem. Zeitschr.* 200(1/6): 145-148. 1928.—Arterio-sclerosis, antagonism between mono- and di-valent cations, effects of hypertonic solutions not containing Ca^{++} or Mg^{++} ions, and vaso-motor activity, are ultimately due to changes in capillary-electric potential between the inner surface of the blood vessels and the circulating blood. In combating acidosis by the injection of extra buffer salts attention should be paid to possible effects of the accompanying changes in the concentration of the various anions. Adsorption of HCO_3' to the surface of the blood vessels after excessive injection of $NaHCO_3$ may lead to deposition of $CaCO_3$ and so constitute the primary chemical change in sclerosis. Injection of hypertonic solutions causes great variations in the cholesterol content of the blood, which may rise to 1.5 times its normal value.—*T. R. Parsons.*

265. **SEN, KSHITISH CHANDRA. Electrolyte antagonism with inorganic suspensions and the equilibrium between sodium and calcium ions in biological systems.** *Allahabad Univ. Studies* 3: 101-118. 1927.—By choosing suitable mixtures, antagonism in certain salts can be shown in nearly all colloids. The contention of Clowes (that the physical structure of protoplasm which regulates the intake of foodstuffs and the output of waste products is analogous to that of the reversible emulsion systems) is therefore justified from a consideration of the physical factors operating in the growth and activity of cell life.—*H. I. Corey.*

266. **[SCHRÖDER, V. N.] ШРЕДЕР, В. Н. Влияние электролитов на пограничную разность потенциалов у Euglena ehrenbergii. [Influence of electrolytes upon the difference of potential of the cell wall in Euglena ehrenbergii.]** Труды Второго Съезда Зоологов, Анатомов и Гистологов СССР. (Proc. 2nd Congr. Zool. Anat. and Histol. of USSR.): 167-168. 1927.—Reactions to stimulation as well as to electrolytes of various concentrations were studied. Normal cells move

to the anode in the electric field. Overcharging is deleterious. Acids slow down the movement, which reaches a maximum in a basic medium. NaCl and $CaCl_2$ lower the charge in high concentrations and decrease motility. The cataphoretic speed of movement of a living cell in the electric field is believed to be the function of the difference in potential.—*O. Gankin.*

267. **SIMON, I. Sulla proprietà che hanno alcuni anioni di abbassare la viscosità dell'acqua e del siero di sangue in vitro, e del sangue nell'animale vivente. [Lowering of the viscosity of water and blood serum by anions.]** *Arch. di Farmacol. Sper. e Sci.* 50(3): 64-66. 1929.—Cl′, Br′, and I′ lower the viscosity of distilled water, and depress in vitro and in vivo the viscosity of blood. The salicylic anion has the same power.—*A. Jappelli.*

Biol. & Med.* 26(9): 811-813. 1929.—Although there are individual differences in segments, as a rule those immersed in Locke's solution maintained at a higher level and for a longer period of time than do those in Tyrode's solution.

269. **WERNICKE, RAÚL, und FERDINAND MODERN. Die oligodynamische Wirkung des Silbers.** *Biochem. Zeitschr.* 214(1/3): 187-197. 2 fig. 1929.—From 9 experiments it is concluded that distilled water which has taken on oligodynamic activity through direct contact with metallic Ag contains 0.000,05 mgm. of this metal per cc. in solution, in the ionic state. This activated water loses its activity completely if subjected to long-continued electrolysis, during which deposit of the dissolved silver may be observed at the cathode. From this, with researches earlier reported, it is concluded that the activation of distilled water results from the formation of an ionized solution. The germicidal property of Ag and Cu solutions also are observed in an atmosphere of H_2 without O_2, which indicates a poisonous effect from the metallic ion. The presence of O is necessary only for the oligodynamic activation through contact with metals, since it permits solution of the latter.

270. **BACHEM, A. The ultra-violet transparency of the various layers of human skin.** *Amer. Jour. Physiol.* 91(1): 58-64. 1 pl., 1 fig. 1929.—The exponential law of absorption does not hold accurately for various thicknesses of sections on account of reflection, scattering, and fluorescence (under certain conditions). The skin cannot be considered as consisting of a series of layers with identical absorption. The various layers show pronounced absorption differences. A comparison of the absorption curves of the various skin layers suggests that the antirachitic effect is produced in the stratum corneum or granulosum and that the erythema originates in the stratum germinativum or corium.—*Author's summary.*

271. **BARKER, W. F. Some effects of light.** *S. African Jour. Sci.* 27: 23-38. 1930.—An address reviewing the principles of photochemistry, with application to photography, vision, and photosynthesis.

272. **BODENHEIMER, F. S. Über die Temperaturabhängigkeiten von Insekten. III. Die Beziehungen der Vorzugstemperatur zur Luftfeuchtigkeit der Umgebung.** *Zeitschr. Wiss. Biol. Abt. C, Zeitschr. Vergleich. Physiol.* 13(4): 740-747. 1931.—Varying humidities of the air (0-100%) in the temp. cage did not influence the preferred temp. of *Calathus fuscipes, Adesmia clathrata,* and *Zophosis punctata.* Maintenance for a long preliminary period in various humidities called forth a distinct shift in the preferred temp. which occurred in various directions according to the extreme degrees of moisture. Since with increasing age the preferred temp. shifted, it seems reasonable to attribute the phenomena of a preferred temp. in cold-blooded animals to the viscosity of the plasma or the water equilibrium of the tissue or of the whole body.

273. **BROUWER, E. Harmonische analyse van temperatuurcurven. [Analysis of time-temperature curves by means of harmonic functions.]** *Nederlandsch Tijdschr. Geneesk.* 72(43): 5319-5342. 5 fig. 1928.—It is proposed to represent the daily fluctuations of the body temp. by means of a trigonometric series:

$$\eta = A_0 + R_1 \operatorname{Sin}(S_1 + 15\chi) + R_2 \operatorname{Sin}(S_2 + 30\chi) + R_3 \operatorname{Sin}(S_3 + 45\chi).$$

In this equation η is the temp., χ the time reckoned in hrs., and A_0, R, S, are constants. The analysis of several time-temp. curves of normal persons, published by Jürgens, Jaeger, and Völker, shows that the time-temp. curve is composed of 2 components, each of which has approximately the form of a sinusoide. The fluctuation represented by one of the components depends upon well known influences: eating, sleep, muscular exercise, intellectual work, etc. The fluctuation represented by the other component curve seems to depend upon factors as yet unknown. The amount of the fluctuation is probably of the order of magnitude of 0.5°C. The maximum of the fluctuation lies approximately at 16 hr.—*J. W. Langelaan.*

Syphilis* 14(3): 346-365. 7 pl. 1930.—An apparatus and method for heating animals with short radio waves are described. Of 25 rabbits infected intratesticularly with *Treponema pallidum* and heated as described, 21 failed to develop chancres when treatments were begun 4, 5, and 7 days after injection. Of these 21, 5 developed nodules in their testes during the treatments, but by intensifying the exposures the lesions disappeared. One treated rabbit developed a chancre, while the testes of a 2nd became enlarged, edematous, and indurated. By increasing the duration and number of heatings they became normal. One rabbit died from overheating and 1 from an intercurrent infection. Of 20 control rabbits, 18 similarly infected developed the typical lesions of experimental syphilis; 2 died 3 days after injection from peritonitis.—*Authors' conclusions.*

275. **CRINIS, MAX de. Über die Photoaktivität des nervösen Gewebes.** *Jour. Psychol. u. Neurol.* 37(1/3): 450-457. 4 fig. 1928.—If removed from the cadaver as quickly as possible, the human brain has the ability, after 8 hrs. irradiation with sunlight, to blacken a photographic plate which is exposed to it for 40 hrs. The same result is obtained after 1½ hrs. irradiation with the Kromayer or quartzlamp. The white matter is more active than the cortex. Medullated peripheral nerve may be distinguished from non-medullated sympathetic nerve by its greater photoactivity, which is dependent upon the presence of definite substances (doubtless lipoids) which may be extracted with ether and chloroform. After extraction with ether and chloroform the brain loses its photoactivity. Lecithin is one of the most photoactive substances of the brain lipoids; before irradiation it will blacken the photographic plate and is particularly active after irradiation with sunlight or the quartzlamp. Cholesterin is not rendered photoactive by the same

period of irradiation which renders the brain so. The photoactivity of the brain is destroyed by fixing in formol. The ability of the sun's rays to render organic matter photoactive differs at different times of the yr. In autumn a decrease in the photoactivity of brain tissue was observed. The photoactive effect is not conditioned by a particular wave length, but is probably brought about by a particular form of active O which is formed by oxidation processes through the disintegration of inactive (passive) O molecules.—*Author's summary (transl. by H. F. Blum).*

276. **GENTNER, WOLFGANG, und KURT SCHWERIN. Über den Zeitfaktor der Strahlungsreaktion des Eiweisses.** *Strahlentherapie* 37(4): 788-794. 5 fig. 1930.—Fractionated albumin solutions were irradiated with ultraviolet light from a quartz Hg vapor lamp. The course of the resulting reaction was followed by counting the number of albumin particles in Brownian motion. For an intensity range of 1 to 1400, a single time factor smaller than 1 was found, i.e., the course of the reaction is given by the equation: $I\,T^{0.904}$ = const. The relation of this albumin reaction to biological effects of irradiation is discussed.—*W. Gentner (transl. by W. C. Boyd).*

277. **GESENIUS, HEINRICH. Über die Gurwitschstrahlung menschlichen Blutes und ihre Bedeutung für die Carcinomdiagnostik.** *Biochem. Zeitschr.* 226(4/6): 257-272. 2 fig. 1930.—The method of Gurwitsch and Salkind, using yeast cells as detectors, was applied to the bloods of 145 persons, healthy and diseased. The blood of 30 healthy persons invariably restricted respiration (radiation effect) by 14.3-100%. Of 33 carcinomatous bloods, only 1 restricted respiration by more than 4%; a slight acceleration up to 4% (limits of error ± 2.5%) was apparent in some cases. Results similar to those obtained in carcinoma were reached in 14 cases of disease characterized by severe anemia (pernicious anemia, leukemia, sepsis, lymphogranulomatosis). In 68 miscellaneous cases various radiation effects were obtained, % of inhibition of respiration, on the whole, running lower than those in health. In 52 experiments, using as indicator the fermentation of the juice of macerated yeast cells, results were obtained comparable with but less constant than those obtained from the respiration of whole yeast cells.

278. **HAUSSER, K. W. Einfluss der Wellenlänge in der Strahlenbiologie.** *Strahlentherapie* 28(1): 25-39. 1928.—With a special apparatus to produce homogeneous rays, it was found that erythema production begins in the ultraviolet region near 300mμ, rises suddenly to a maximum at about 297mμ, then falls sharply to a minimum at about 280mμ, again rises to a 2nd maximum at about 250mμ, after which it seems to fall, although this could not be determined. A qualitative difference in erythema exists according to exciting wavelengths; the shorter the waves the faster the rise and fall in time of erythema and pigmentation. With shorter wavelength, much larger doses can be given without bleb formation. The absorption maximum of light by the skin is at about 280mμ and a 2nd maximum of permeability occurs at about 250mμ. The relative intensity for lines 297mμ and 366mμ were 45: 248. The absorption coefficient between 297mμ and 366mμ is at 4: 1, while the difference in erythema action is 1000: 1, for which no explanation can be offered.—*P. M. Suski.*

279. **KOLLATH, W. Gewebsatmung und strahlende Energie. Über eine Methode, an vitalangefärbten überlebenden Zellen antagonistische Wirkungen kurz- und langwelliger Strahlen auf die Oxydations-Reduktions-Potentiale der Zellen zu demonstrieren.** *Strahlentherapie* 35(3): 444-488. 9 fig. 1930.—When fresh epithelial cells from pigeons stained with methylene blue are exposed to light of long wave lengths, the methylene blue is reduced, and will remain reduced unless the cells are exposed to blue or ultra-violet light. In pigeons suffering from beri-beri the methylene blue is not reduced by the long wave lengths. Cells from starved pigeons show a greater reducing power.—*W. Kollath (transl. by F. Bernheim).*

280. **KUČERA, CYRILL. O vlivu ozařování rtuťovou lampou (ultrafialovými paprsky) na vývoi mladých zvířat a jeho posouzení z hlediska zootechnického. [The influence of ultra violet radiation from a quartz mercury lamp upon the growth of young animals and its zootechnical significance.]** *Biol. Spisy Vysoké Školy Zvěrolékařské Brno. (Publ. Biol. Ecole Vétérinaire Brno)* 7: (195-225). 1928.—The radiation of eggs by means of the Hg quartz lamp (unfiltered lights) has usually a favorable influence upon the number of chickens. Radiation of young rabbits sometimes favored the increase in wt. of individuals and sometimes hindered it. Radiation of guinea pigs showed the largest increase in wt. for the lightest animals. Overdosage with u. v. radiation only had a relative bearing, that is, in regard to the stage of development and the wt. of the chicken in the 2nd period (30-60 day old), which was later improved by the further growth of the animals. Radiation does not change the blood picture. It is concluded that the radiation of young animals cannot be properly judged from the point of view of their development, since the favorable influence which was observed is mostly on weak individuals and is directly injurious from the breeder's point of view. Therefore, radiation seems to influence the development of the skeleton and regulates general development.—*O. Glasser.*

281. **KUNTZEN, H., und W. VOGEL. Histologische Untersuchungen über die Wirkung chirurgischer Diathermieströme.** *Arch. Klin. Chir.* 164: 39-57. 8 fig. (1 col.) 1931.—The action of the diathermy current on the liver of rabbits and dogs was comparable to its action elsewhere in the body. A section of the liver was excised from 1 lobe with the coagulation current and at a considerable distance an incision made with the "Schmelzschnitt." Some animals were killed 0, 3, 6, 12, 24, 48, 72 hrs., 7, 12 days, 5 wks., or 4 or 7½ mo. thereafter; others were injected with 10 cc. colloidal India ink by way of the portal vein, then killed. A broad area of the surrounding tissue undergoes immediate heat necrosis. After a few days' attempt at demarcation, a further area undergoes necrobiosis. This area initiated connective tissue proliferation at the periphery which binds it to the healthy tissue; the sequester is thus encapsulated but not sloughed, and resorption within the connective tissue capsule occurs in the course of months. Hemostasis occurs by shriveling and occlusion of the vessel walls; thrombi occurred only in the necrotic area. There was no selective deep action of the current on the blood vessels beyond the area of necrotic tissue. Secondary hemorrhages did not occur because the sequester acts as a tampon. The difference between the coagulation and the "Schmelzschnitt" current lies in the fact that the latter incision does not char and form a scab and the primary necrosis is minimal. The immediate changes and the reaction of the tissue are similar to the coagulation current. The secondary zone of necrosis in the "Schmelzschnitt" incision is surprisingly large and the primary union with sutures therefore appears unreliable.

282. **LEPESCHKIN, W. W. The thermic effect of death and hemolysis.** *Amer. Jour. Physiol.* 95(2): 473-480. 1930.—Experiments made on red blood corpuscles confirmed former experiments on the thermic effect of death, determined on yeast cells. The hemolysis or the coagulation of protoplasm of red corpuscles is accompanied by the production of heat to the amount of 2.1-2.4 calories per gm. of dry substance of corpuscles. The death of red corpuscles as well as that of yeast cells is therefore an exothermic process. This confirms the supposition that death is accompanied by the decomposition of some very unstable chemical compounds. In the case of red corpuscles, they are probably the compounds of hemoglobin with sterins and phosphatids. As the molecular wt. of hemoglobin is not less than 16,600, the decomposition of the molecule of its unstable chemical compounds forming the protoplasm of red corpuscles is accompanied by the production of at least $2 \times 16{,}600 = 33{,}200$ calories. This thermic effect is greater than that

produced by the destruction of the molecule of some explosive substances.—*Author's summary.*

283. **LIPPAY, FRANZ. Über Wirkungen des Lichtes auf den quergestreiften Muskel. IV. Versuche mit ultraviolettem Licht an nichtsensibilisierten Kaltblütermuskeln.** *Pflüger's Arch. Ges. Physiol.* 226(4/5): 473-480. 5 fig. 1931.—Frog muscle was exposed to ultraviolet light (250-400 mμ) from a quartz lamp. Heating effects were prevented by using flowing saline 3 cm. thick above the muscle. Exposure for 30 min. produced a contracture. The effects became evident in 1-2 min., and some after-effects were observed even after the light was removed. Contractures could be induced in denervated muscle, in muscle paralysed by immersion in 0.2% KCl or in 6% cane sugar solutions but not in dead muscle. The contracture is irreversible and is accompanied by diminution of excitability, which is completely lost when the degree of contraction is much below that of maximal tetanus. The condition is similar to the contracture induced by visible light rays on sensitised muscle.—*H. C. Bazett.*

284. **MEINERI, PIER-ANGELO. Contributo allo studio delle differenze reazionali e fisiologiche della cute umana normale nei suoi vari territori. [The reactional and physiological differences of the normal human skin in its different regions.]** *Arch. Ital. Dermatol., Sifilogr. e Venereol.* 3(1): 15-24. 1927.—Histological examination of strips of skin from the back and legs irradiated with ultra-violet rays has shown, 24 hrs. after irradiation, a reactivity of various degrees manifested chiefly by a lymphocytic infiltration on the back while the infiltration on the legs consists of polynuclear neutrophils. The leucocyte count of the blood taken from the zone of the skin irradiated by u.-v. rays, 24 hrs. after irradiation, shows an augmentation of the lymphocytes in the skin of the back and, on the other hand, an augmentation of the polynuclear neutrophils in the skin of the legs. The serum extracted from the skin of the back by means of plaster of cantharides contains a larger quantity of albumin than the serum extracted in the same way from the skin of one of the legs (in average a difference of 1%). This indicates that the skin in its different parts has different properties and tendencies, probably related to the needs of each region.—*Author's summary (transl. by B. J. Luyet).*

285. **MILLER, D. F. Determining the effects of change in temperature upon the locomotor movements of fly larvae.** *Jour. Exp. Zool.* 52(2): 293-313. 3 fig. 1928.—Temperature is an important factor in the behavior of insects. Apparatus was devised and constructed to control all important factors and to measure their effects. The material used was a pure culture of the blowfly, *Lucilia sericata* Meigen, reared from a single original ♀ and inbred for a number of generations before tests were made. The experimental work was divided into 2 divisions: observational, with results based upon averages obtained from data collected by timing with a stop-watch the movements of the larvae through the apparatus at different temp.; and graphic, made by the operation of a kymograph drum by individual maggots. The results obtained from the 1st method are expressed by curves and tables and those of the 2nd are self-recorded. The 2nd method fully substantiates and explains the 1st. There is a very intimate relation between temp. and rate of locomotion; change of temp. does not affect the height of contractions, except at very high and very low temp.; at all degrees the rate of contraction varied directly as the temp.; and within normal limits, the rate of locomotion depends upon the temp.—*Author (courtesy Wistar Bibl. Serv.).*

286. **MIURA, UNICHI. The effect of variations in relative humidity upon skin temperature and sense of comfort.** *Amer. Jour. Hyg.* 13(2): 432-459. 1931.—Studies on 5 subjects (including the investigator) show that the skin temp. of the forehead and over the carotid of a man, normally clothed and sitting in still air, tends to vary directly with the relative humidity of the air at 60°-80° F., although the variation is small. The rate of variation is larger at 70° and 80° F. than at 61-62° F. The variation for a difference of 50% in relative humidity observed with the 5 subjects averages 0.3° C. on the forehead and 0.2° C. over the carotid at 70° F. dry bulb temp., 0.2° C. on the forehead and 0.1° C. over the carotid at 61-62° F. dry bulb temp. The sense of warmth tends to vary with the relative humidity at dry bulb temp. at 60-80° F.; and the rate of variation increases with a rise in the dry bulb temp. This relationship coincides with the effect of humidity upon skin temp. A difference of 50% in relative humidity is evidently perceptible for ordinary persons at dry bulb temp. of 70-80° F. under conditions stated above. A difference of 20% in relative humidity at 70° F. and a difference of 50% at 61-62° F. are probably beyond the power of perception. The effect of relative humidity upon the sense of warmth is in accordance with the effective temp. concept for dry bulb temp. at 60-80° F. The magnitude of the effect obtained on the average for the 5 subjects was somewhat less than would have been expected from Yaglou's thermometric chart. A difference of 50% relative humidity corresponded in its effect upon the sense of warmth with a difference of 1.7° F. in dry bulb temp. at 61-62° F. at a constant relative humidity, and to a difference of 4.0° F. at 70° F. The rates calculated from Yaglou's thermometric chart are 2.5° F. at 61° F., and 4.6° F. at 70° F. on the average for different humidities. Relative humidities of 70% and above cause an uncomfortable feeling of wetness at 70° F.

Bot.* 24(1): (5-13). 3 fig. 1930.—The mitogenetic rays cannot be the immediate cause of mitosis, since mitosis takes place in a specialized and localized manner in tissue presumably uniformly exposed to the rays. Examples are given. The hormone theory of Haberlandt is favored.—*W. G. Boyd.*

288. **SCHALL, LUTZ. Untersuchungen über den Ablauf des Lichterythems.** *Strahlentherapie* 28(1): 164-167. 3 fig. 1929.—The course of the erythema reaction produced by ultra-violet light upon the skin of 300 persons was investigated by means of an "erythemameter," which consists of various scales of reddening and takes into account the natural color of the skin. In spite of precautions taken in the determination of the course of the erythema reaction, wide variations existed in different individuals under the application of identical doses, and the qualitative and quantitative course of the reaction was different in each individual, but certain types of reaction could be collected in groups. There is usually a rapid increase of the skin reaction to a maximum, which occurs in 60% of the cases between the 5th and 9th hr. after treatment. In most cases a definite wave form of the reaction could be observed. The latent period was 1-7 hrs. with an average of 2 hrs. Investigations of the threshold value of the dose, of the effect of subdivided doses, of the increase of reddening with increasing the dosage, etc., complete the report.—*O. Glasser.*

289. **SCHMIDT-LABAUME, F., und E. UHLMANN. Über den Einfluss des Luftdrucks auf die Erythem- und Pigmentbildung der Haut.** *Strahlentherapie* 38(1): 54-57. 1 fig. 1930.—With a Kromyer quartz lamp and a chamber constructed to give 20 cm. Hg negative pressure and 8 cm. Hg positive pressure, the exposure of skin of a number of persons shows that the erythema and pigmentation under positive pressure is weaker and that under negative pressure is stronger than under normal pressure.—*P. M. Suski.*

290. **SCHMUTZLER, ERICH. Der Temperaturkoeffizient des Sauerstoffverbrauchs überlebender Organe.** *Pflüger's Arch. Ges. Physiol.* 226(2): 294-304. 2 fig. 1930.—The hind limb of a dog was perfused with defibrinated blood and the O consumption was determined by gas analysis. The limb was cooled or warmed by varying the temp. of the inflowing blood and by local cooling

of the limb. Temp. was measured in the muscle of the limb with a fine Hg thermometer (Zondek's pattern) and also in the rectum. O consumption was unchanged even after several hrs. if the temp. was constant. O usage showed a linear relationship to temp., a fall of 1° decreasing the amount used by 3%. Studies of the O usage of nucleated red cells (goose) gave similar results; in this case the O consumption was reduced 4% by a fall of 1°.—*H. C. Bazett.*

291. SEIWELL, H. R. Influence of temperature on the rate of beating of the heart of cladocerans. *Jour. Exp. Zool.* 57(2): 331-346. 1930.—Various specimens of the fresh-water cladoceran, *Simocephalus exspinosus*, were subjected to a wide range of controlled temp. to study the influence of temp. on the rate of heart beat. A very definite general correlation between temp. and heart beat prevailed: the higher the temp., the faster the heart. The rule of correlation is not simple; in many of the experiments there were breaks in the continuity of change of rate, these breaks for the different animals not appearing at any particular point on the temp. scale. For the group of animals examined, the diversity in rate of heart beat is widest at high temp. The heart-frequency temp. coefficients for 10° intervals steadily decrease toward the higher scale of temp. Straight-line fittings to the individual log-frequency temp. graphs indicate one or more changes in the rate of acceleration of heart beat over the temp. scale. These changes, or "critical points," were not very narrowly localized. The log-frequency temp. plotting of the average frequencies for all animals showing greatest regularity of response could be fitted by 2 straight lines, the break or "critical temp." occurring in the neighborhood of 13°. From the above plotted data a tentative computation of the critical thermal increment, μ, of the Arrhenius equation, for each line gave a value of 19,700 calories for the temp. range of 4° to 13° and 7289 calories for the temp. range above 13° C.—*Author (courtesy Wistar Bibl. Serv.).*

292. SHEARD, CHARLES, and GEORGE M. HIGGINS. The influence of irradiation by air-cooled quartz-mercury arcs on the incubation of eggs. *Jour. Exp. Zool.* 57(2): 205-222. 5 fig. 1930.—The average daily loss of wt. for each hen's egg without irradiation by quartz-Hg arcs is about 0.35 gm. under normal incubation and about 0.20 gm. under conditions of abnormal incubation caused by excessive humidity. The average daily loss of wt. is increased by irradiation. The period of incubation is shortened in about 25% of irradiated eggs under normal incubation. Incomplete closure of the body cavity is the general rule in unphysiological incubation without irradiation. The use of quartz-Hg arcs tends to produce more nearly normal development in this respect. The shell and its membrane transmit ultraviolet to about 300 mμ; the membrane of the eggshell, to about 270 mμ. The stimulating action of irradiation by quartz-Hg arcs may be due to absorption of u.-v. energy or the absorption of ionized gases produced by such arcs. With the eggshell removed, but with membrane intact, the aperture being closed with quartz or glass, irradiation occurring daily for 30 sec., normal development of embryos occurred under glass cover-slips, whereas marked modifications were produced by such irradiation through quartz. In general, irradiation of eggs with air-cooled quartz-Hg arcs tends to increase the rate of metabolism of incubating eggs, and u.-v. irradiation is an accessory in maintaining normal metabolism and development of incubating embryos.—*Authors (courtesy Wistar Bibl. Serv.).*

293. SIEBERT, WERNER W. Die mitogenetische Strahlung des Blutes und des Harns gesunder und kranker Menschen. *Biochem. Zeitschr.* 226(4-6): 253-256. 1930.—Mitogenetic studies were made of the blood and urine of 130 persons, both normal and diseased. In both classes the behavior of the blood and urine was, in the main, parallel. Both blood and urine of healthy persons emitted mitogenetic rays. The suspension of radiation from the blood of patients with certain diseases (malignant tumors, severe anemias, leukemias, and febrile diseases), previously described by Gurwitsch and Salkind, was confirmed.

294. TAKAHASHI, TOKUE. The transmission of ultra-violet rays through animal tissues. I. II. *Brit. Jour. Actinotherapy* 5(3): 69-72. 4 fig.; (4): 101-103. 4 fig. 1930.—Spectral photographs show that the living skins of rabbits, thicker than 0.1 mm., practically do not transmit rays of wavelengths shorter than 2,900 A.U.; when thicker than 1 mm. little is transmitted shorter than 3,650 A.U. Fascia transmit relatively more u. v. rays than skin. The ratio of intensities of transmitted and incident u. v. rays is generally very minute; in the living skins of rabbits thicker than 0.25 mm. it is less than 1/1900-1/48000, depending on the wave-lengths of the incident u. v. rays. The transmission through living skins of rabbits is as meagre as when they are removed from the animal bodies. Removed white human skins transmit more u. v. rays, compared with those of rabbits. When, however, they are thicker than 1 mm. they hardly transmit more than ratios 1/1000-1/20000, depending on the wave-lengths of the incident light. The shortest wave-length transmitted in the experiments was 3,130 A.U. Changes of transmission of the rays during the course of experiments were traced to variations of blood circulation. One of the factors controlling the transmission of the rays through living skins is the condition of blood circulation. Evidence shows u. v. rays incident on skin can reach circulating blood in rabbits. A comparison of the transmission of u. v. rays through skins in the bloodless and the congested states leads to an estimation of absorption of the rays within circulating blood of rabbits. With skin 0.25 mm. thick, the absorption of the rays in circulating blood was not more than 1/1900-1/50,000 parts of the incident rays as the wave-length decreases from 3650-3025 A.U. The amount of the rays which reach circulating blood decreases markedly as the wave-lengths become shorter.—*Author's summary.*

ANIMAL PHYSIOLOGY

ELECTRICITY, X-RAY, RADIUM

(See also in this issue Entries 248, 323, 331, 346, 352, 365, 408, 979, 1078, 1134, 1140, 1403, 2340)

295. BACHEM, A. The resistance of various tissues for various electric currents. *Arch. Phys. Therapy, X-Ray, Rad.* 11(8): 391-394. 1930.—Experiments under 3 different conditions (in vivo; with organs left in position, immediately after the dog had been killed; with organs removed, kept on ice 1 night, then brought back to nearly room temp.) were made on liver, spleen, muscle, shaved skin, subdermal fat, inflated and collapsed lungs, bone, and blood of a dog, the organs being exposed to direct current (0-6V, 0-1 MA), alternating current (0-6V, 0-1 MA, produced by an automatic commutator, about 20 periods per sec.), and high frequency current (0-200 MA, 20-40 V. eff., 1000-2000 V. peak). The same organs were taken from fresh bodies and exposed to the same 3 kinds of currents. Resistance depended very strongly on the current used; it was smallest for high frequency, medium for low frequency, and greatest for direct current. In the case of direct current it increased rapidly in the beginning and slowly later on. In most cases there was a tendency toward an increase of resistance from life to death; the resistance was still higher after the tissue was kept on ice for a day, an exception being the skin. From these experiments one notes that skin resistance was comparatively low for high frequency, and very high toward direct current; the resistance of high frequency current was the same for dry and moistened skin. Bone resistance depended very pronouncedly upon the specimens observed; it was small for the porous bone

of the skull (calvarium) and high for the solid bone of the tibia.

296. BAGG, HALSEY J., and C. ROBERT HALTER. Experimental studies on tissue reaction to radiation using a segment of a growing mouse tail as a biological indicator. *Amer. Jour. Roentgenol.* 24(6): 640-647. 5 fig. 1930.—A 5-7 mm. segment of the tail of a young mouse (9-12 cu. mm. of tissue) can be used to advantage as a measure of the biological effects of irradiation. The degree of irradiation effect may be measured in terms of epilation disturbance, in retardation in the growth of the tail, or in the spontaneous amputation reaction.—*Authors' conclusions.*

297. CRILE, GEORGE W., MARIA TELKES, and AMY F. ROWLAND. An experimental investigation of the physical nature of death. *Proc. Amer. Philosoph. Soc.* 68(2): 69-81; 8 fig. 1929.—Experimental evidence is cited to show that (1) in animals and plants, an electric potential exists which disappears on death. Increased potential, brought about by inserting an electrode into a living amoeba, made it more active; lowering the potential rendered it less active, until it finally died and broke up. It is inferred that the organic molecules bound together in the animal organism are maintained thus by electric force. Also a living apple showed a definite potential. (2) Insomnia produces a progressive loss of potential, ending in death. (3) At death the p. d. drops to zero. It is concluded that it is the charge on the films of cells which gives the organism its adaptive property. Life is a potential maintained and varied adaptively with environmental conditions, the p. d. being maintained by chemical activity, mainly oxidation. In unicellular organisms, life is an adaptively changing p. d. between the cytoplasm, nucleus and medium, in higher organisms between the brain and other tissues, especially the liver. Death is the absence of difference of potential—final equilibrium.—*A. J. M. Honeyman.*

298. DUBOST, JEAN. Les bases physiques de la radiothérapie. 104p. 50 fig. Gauthier-Villars: Paris, 1928. Pr. 10 fr.—The progress made in electrical apparatus during the last 10 yrs., permitting the therapeutic utilization of more and more penetrating x-rays, with voltages up to 200,000, has made it necessary to reconsider the physical side of the problem, and, along several lines, to develop new technique. This the author has attempted to do. After reviewing some ideas of electricity and general physics, he investigates those properties of x-rays, hard and soft, which have a direct bearing on radiotherapy, omitting everything which has no direct connection with therapy. He pays particular attention to filtration and of ionometric measurements.—*J. Dubost (transl. by E. H. Quimby).*

299. ELLINGER, PH., und E. GRUHN. Über biologische Röntgenstrahlenwirkung. IV. Über die Verstärkung der Röntgenstrahlenwirkung durch Sekundärstrahlung. *Strahlentherapie* 38(1): 58-97. 3 fig. 1930.—The blackening of a photographic emulsion by secondary rays increases with the hardness of the primary rays and with the atom number of secondary rays. This latter increase is not linear, maxima occur, which are displaced with decreasing wave-length toward elements of lesser atom number. In filtration experiment with Al foil it was shown that the effect of secondary rays on photographic plates is due to secondary rays of high penetrability, and indeed probably to fluorescent rays of various series. *Bacillus prodigiosus* cultures begin to be injured by dose of over 500 r, and are killed relatively faster as the dose increases at between 1000 and 3000 r, although a certain % survives doses of over 15,000 r. By using secondary rays with higher atom number, cultures may be rapidly killed with smaller doses of primary rays; in fact, complete sterilization may be made with about 300 r. With primary rays of various wave-lengths, medium wave-length (100 KV) have the greatest lethal efficiency. With the use of secondary rays, the killing effect increases with increase in wave-length of primary rays (the dose of the primary remaining the same). Bactericidal action of pure primary radiation depends to a slight degree on the ray density; with the same dosage, greater effect is obtained by rays of lesser than of greater density. When using the secondary rays the density of the primary rays is of no importance. The bactericidal action of secondary rays increases with the atom number of the secondary rays, forming characteristic maxima and minima, the positions of which depend on wave-lengths of primary radiation. Bactericidally active rays have very little penetrability, and are almost entirely absorbed by a layer of air 4-5 mm. thick. The more active the rays, the less their penetrability. Bactericidally active secondary rays which are produced by hard primary rays have higher penetrability than those which are produced by softer primary rays. It is concluded that the bactericidal activity of röntgen rays is primarily due to photo-electrons of 1st and 2nd order, and is distinctly retained even when the secondary rays are thinned down to 1%.—*Authors' summary (transl. by P. M. Suski).*

300. FUKASE, SHUICHI. Experimentelle Untersuchungen über die Wirkung der Röntgenstrahlen auf die Callusbildung. *Virchow's Arch. Path. Anat. u. Physiol.* 277(1): 69-92. 19 fig. 1930.—Both fibulae were subcutaneously broken in 84 young rabbits, and the lesions on one side in each case irradiated with heavy, medium or light x-ray doses on 4 successive days. The subjects were examined microscopically, roentgenologically, and with the naked eye, at 8-hr. intervals up to 48 hrs., then at various daily intervals up to 7 wks. In the heavy dose series (10 rabbits, dose 32 H—1600 r) up to 3 wks. bone-formation was completely suspended, its place being taken by a compact, peculiarly shaped connective tissue with cells resembling bone cells. After 3 wks., in the previously poorly vascularized connective tissue, vessels began to form, around which new bone formation proceeded vigorously. Healing was more rapid on the non-irradiated than on the irradiated side of the same animal. Irradiation with moderate x-ray doses (60 rabbits, dose 8 H—400 r) also decreased the amount of callus formation; yet it produced earlier healing on the irradiated than on the non-irradiated side, recognizable in x-ray pictures by earlier onset of calcification and earlier replacement of the previous callus. Macroscopically the results of medium irradiation were recognizable through the lower vasculanity and greater calcification of the bony cicatrix on the irradiated side. Microscopically it was evident that the original traumatic inflammation during wound healing was less, the granulation cells assuming spindle forms earlier under irradiation and fibrilla formation beginning earlier. Vascular new formation was more limited on the irradiated side, the mass of the preliminary bony trabeculae lessened in extent, though the structure of the individual trabeculae is not altered. The bony cicatrix produced after the destruction of the superfluous bony trabeculae was earlier completed. The new-formed bone had a broader periosteal covering on the irradiated than on the non-irradiated side. The periosteum did not present the ordinary bundle appearance, but formed an irregular fibrous fabric composed of interlacing connective tissue fibrillae with infrequent nuclei. This change was characteristic for the irradiated lesions. Since after x-ray irradiation the cells concerned in ossification are transformed into connective tissue cells, which after a latent period of several weeks may again become ossified, the conclusion seems justified that the capacity for bone-formation is present in all connective-tissue cells. The roentgenologic findings are described in an earlier paper.—*Author's summary (transl.).*

301. GLOCKER, R., H. LANGENDORFF, und M. LANGENDORFF. Zur Frage der "spezifischen" Wirkung der Kathodenstrahlen auf die Zelle. *Naturwissenschaften* 19(11): 251. 1931.—Axolotl larvae, irradiated with a dose of 100,000 r, using a high tension tube which yields a dose of 500,000 r in 12 min., showed the same abnormal mitoses as were reported by Politzer and Pauli (see this issue Entry 309) as resulting from cathode rays. This

is not in accord with Politzer and Pauli's views as to the specificity of the effects of cathode rays.

302. **HUBERT, R. Der Einfluss der Röntgenstrahlen auf die energieliefernden Reaktionen des wachsenden Gewebes.** *Pflüger's Arch. Ges. Physiol.* 223(3): 333-350. 1929.—The glycolysis of growing and not-growing tissue of chicken embryos was determined by Warburg's manometric method in order to study the effect of previous roentgen irradiation upon it. The glycolysis was by far more radiosensitive than other energy-providing reactions which were examined. The radiosensitivity of glycolysis was compared with that of growth itself, finding that the ability to grow is damaged earlier by x-rays than glycolysis. Glycolysis retardation can, therefore, not be the cause of damage to the growth.—*O. Glasser.*

303. **LANGENDORF, H., und M. [LANGENDORF]. Strahlenbiologische Untersuchungen an den Keimzellen des Seeigels.** *Strahlentherapie* 40(1): 97-110. 9 fig. 1931.—The action of 50, 100, 200, 300, and 400 r units of x-rays on the sperm and eggs of *Psammechinus miliaris* was tested in 4 series: (1) sperm was irradiated and allowed to fertilize normal eggs; (2) eggs were irradiated and fertilized by normal sperm; (3) eggs and sperm irradiated before fertilization; (4) eggs were irradiated after fertilization. The number of injured larvae increased with increase in the dose, the curve in each series resembling the exponential. Comparison of 1, 2, and 3 showed that the sperm was more sensitive than the egg. The curve in 4 was dependent on the time between fertilization and irradiation, for the phase of nuclear division influenced the degree of injury decidedly. By irradiating at 5-min. intervals after fertilization, the sensitivity of the stages of mitosis was found to be greatest shortly after fertilization, decreasing to a minimum during the metaphase, and beginning to increase again with the anaphase.

304. **MAISIN, J., et E. PICARD. Essai de radiosensibilisation des tissus normaux et des tumeurs. Etude expérimentale.** *Rev. Belge Sci. Méd.* 2(4): 328-335. 3 fig. 1930.—Of 2 groups each of 5 tumor-bearing mice, 1 was intravenously injected twice a wk. for 6 wks. with a colloidal uranium-thorium-ionium mixture; both groups received during the 2nd wk. of injections 3 irradiations of 1500 r. each, or 4500 r. in all. In the uninjected mice the development of the tumor was temporarily checked by irradiation, but afterward resumed, generally increasing then until death. In the injected mice the tumors were generally resorbed inside of 3 wks. without prejudice to the health of the animal.

305. **MARTENSTEIN, H., und M. JUON. Ist die "Grenzstrahlentherapie" nach Bucky vollkommen ungefährlich?** *Strahlentherapie* 26(1): 177-188. 1 fig. 1927.—Small areas of human skin were irradiated with Grenz rays at 5, 6, 7, 8, 9 and 10 K. V. eff., 10 M.A. and 8 cm. focal skin distance with the dose of 10 X (skin unit dose according to Kienboeck). 24 hrs. afterwards, a weak erythema reaction was observed, which became more intense in the next 24 hrs. Formation of pigment was observed after 1 week. The latent period of the erythema was considerably shortened when higher doses (up to 60 X) were used. Histological examination of the radiated skin areas showed considerable damage, even to the deeper parts of the cutis. An erythema dose applied through a filter of epidermis of a mouse produced similar reactions to the application of the unfiltered radiation, with a difference only in the latent period of the erythema.—*O. Glasser.*

306. **MEYER, HEINZ-THEODOR. Über Härtung von Grenzstrahlen durch Luft.** *Strahlentherapie* 38(4): 778-784. 1930.—When grenz ray tubes with Lindemann glass windows are used, the hardening of the rays by increasing the focal distance is greater for higher voltages than for lower. For the latter this air-hardening is so insignificant that in practice one can count on quality remaining the same as long as the voltage is constant. Since the quality of the rays is very dependent on the thickness of the Lindemann glass window, every tube must be calibrated at different voltages by determining the half value thickness for the rays in Al or cellophane. The same holds for the determination of dosage curves in relation to the focal distance. On account of the coating of the Lindemann window with tungsten and the resulting change in transmission of radiation, it is desirable in practice to repeat this standardization from time to time (perhaps every 100 hrs. of operating time) in order to avoid errors in dosage.—*Author's summary (transl. by E. H. Quimby).*

307. **MEYER, J., et J. SAIDMAN. Les rayons X ultramous.** *Bull. Soc. Française Dermatol. et Syphiligr.* 1929 (9): 1251-1254. 1929.—The limit of the x-rays ordinarily used in therapeutics is a little below 1 Å, the longer waves being stopped by the glass. To obtain softer rays it was necessary, while lowering the tension of the tube, to provide it with a window of lower atomic weight. Until recently the softest rays available were the grenz rays (so called because the limit of 3 Å was regarded as the ultimate in therapeutics) of the Bucky tube. About 2 yrs. ago a still softer ray, 4-8 Å in length, was obtained by the use of a tube with a cellophane window devised by Dauvillier and Saidman. Bucky had at first believed that his Grenz rays did not reach the vascular tissue of the corium, and hence could be used without danger of dermatitis; but the investigations of Saidman and R. Cahen showed that half the energy penetrates to a depth of 2 mm. and that the cutaneous vessels are affected. The new 4-8 Å rays are almost entirely absorbed by the epidermis; a layer 34μ deep absorbs half the energy, and the authors estimate that below 1/3 mm. depth hardly 1/100 of the energy remains. The cutaneous vessels, therefore, are not affected, and there is no resultant x-ray dermatitis. A heavy dose may provoke an erythema comparable to that produced by u. v. rays, but slower in progress. These ultra-soft 4-8 Å rays have given "interesting results" in eczema, in varicose ulcer, and dermatites produced by trichophyta, streptococci, and staphylococci. The authors give a schematized comparative summary of the biologic properties and therapeutic results of ultra-soft rays, Grenz rays, ordinary x-rays, and ultraviolet.

308. **MUTSCHELLER, A. Quantum energy of x-rays: a new method of measuring it.** *Radiology* 15(4): 460-470. 2 fig. 1930.—A new method is given for measuring the quantum energy in ergs of x-ray radiation produced at various voltages, and a method of testing dosimeters, i.e., ionization chambers used for intensity measurement, for their dependence or non-dependence on wave lengths. It is pointed out how the clinical aspect of radiation therapy can be simplified by the application of the quantum principle, and that in all probability the clinical effects of x-ray radiation parallel the quantum energy and the total number of the quanta, rather than the total ionization effect. It is suggested that clinical radiation data, and especially quality measurements, be made and recorded in terms of quanta energy or ergs.—*From author's summary.*

309. **PAULI, W. E., und G. POLITZER. Über die Wirkung von Kathodenstrahlen auf die Ruhezellen und auf Karyokinesen von Salamandra maculosa.** *Zeitschr. Wiss. Biol. Abt. B. Zeitschr. Zellforsch. u. Mikrosk. Anat.* 8(3): 404-424. 17 fig. 1929.—Shortly after radiation of the cornea of larvae of *S. maculosa* with cathode rays, 3 groups of changes appear: necrotic changes of the resting cells, similar to the effect of other agents which act only on the superficial layers, and therefore not characteristic for the cathode rays; karyokinetic changes produced by the x-rays, when the cathode rays are stopped by the window and within the tissue; and karyokinetic changes characteristic for the cathode rays, i.e., cells in which the chromosomes are clumped together, and in which there are fine threads stainable with hematoxylin. The authors conclude that cathode rays, recently used therapeutically, need to be investigated further. Differences in the effects of weakly filtered radium preparations and of x-rays are due to the effect of the β rays, which are similar to the cathode rays, and like them probably produce characteristic effects. The common opinion that x-rays act on the tissue by the

secondary β or electron rays released in the tissue is untrue, since the cell changes which are characteristic of cathode rays do not appear in the x-rayed cornea.—*O. Glasser* (*from abstr. by W. E. Pauli*).

310. **PAUSDORF, HANS, und W. NELL. Die Blutdruckschwankungen nach Röntgenbestrahlungen und ihre klinische Bedeutung.** *Strahlentherapie* 38(1): 40-53. 1930.—The blood pressure fluctuation directly following x-ray exposure is to be distinguished from the blood pressure fall which appears after 24-48 hrs.: while the former takes place entirely without regularity, the latter shows a distinctly undulating course, and on intensive exposure repeats itself between the 25th and the 35th day and again between the 50th and the 70th day after irradiation. This fall in blood pressure is not caused by the influence of x-rays on the adrenals, but is an expression of general reaction caused by cell decay and the increase of irritability of vasomotor apparatus evoked by x-rays, as pointed out by Lazarews. It takes an undulatory course exactly like that of x-ray erythema. As an expression of general reaction it is important for prognosis, giving of general therapy and for determining time for re-irradiation.—*Authors' summary* (*transl. by P. M. Suski*).

311. **POHLE, ERNST A., GORTON RITCHIE, and CECIL S. WRIGHT. Studies of the effect of roentgen rays on the healing of wounds. I. The behavior of skin wounds in rats under pre- or post-operative irradiation.** *Radiology* 16(4): 445-460. 20 fig. 1931.—White rats (80) were exposed to 2 qualities of x-rays (100 K. V., 2.0 mm. Al; 140 K. V., 0.25 mm. Cu.+1 mm. Al) preceding or following incisions in the skin. In the 1st group, half of each wound extended into previously irradiated skin; the other half remained in unexposed tissue. In the 2nd group, half of each incision was irradiated following the cutting and the other half was protected. Seven days following the cutting and also after complete healing, the animals were killed and the skin prepared for examination. Irradiation with 1,000 r given in one sitting, of either quality of x-rays, as defined above, from 1 to 30 days before the incision, did not influence the healing process perceptibly. Irradiation with 1,000 r in 1 sitting, with either quality of x-rays, as defined above, immediately, 24 hrs. and 48 hrs. respectively after the incisions, retarded the healing process, particularly in the 24 hr. group, but did not interfere with the final formation of a smooth scar.—*Authors' summary.*

312. **POLITZER, G. Ueber den Einfluss der Roentgenstrahlen auf die embryonale Linse.** *Wien. Med. Wochenschr.* 79(17): 551-555. 2 fig. 1929.—The larvae of urodela were given doses higher than 8 H of x-rays filtered through 1 mm. of Al. After 3 months the lens swelled and burst its capsule, and the swollen lens fibers entered the eye chamber. The remaining portion was absorbed in the 4th month. Abnormal karyokinesis appeared in the lens epithelium shortly after radiation; these cell divisions lead to the destruction of all the dividing cells. Greater defects in the lens epithelium appear later. Only after large sections of the lens epithelium have been destroyed is the lens capsule torn and the lens destroyed. Evidently the lens epithelium plays the important rôle of protecting the lens from swelling. Other causes of lens swelling (increase of permeability of radiated membranes—in this case the lens epithelium—) are discussed, as is the present status of the effect of radiation on the human lens.—*G. Politzer* (*transl. by. Otto Glasser*).

313. **RAJEWSKY, BORIS, und GERHARD GABRIEL. Untersuchungen an sehr weichen Röentgenstrahlen (sogenannten Grenzstrahlen).** *Strahlentherapie* 30(2): 308-333. 11 fig. 1928.—This paper upholds the thesis that Bucky's soft x-rays have no special properties not explainable by absorption coefficients. From 8 KV. to 12 KV. the rays have a continuous increase in transmission through biological specimens. Observations on erythema show that the very soft rays which are absorbed in the surface layers chiefly affect the capillaries.—*H. Kahler.*

314. **SAITO, K. On the influence of radium upon the blood.** [In Japanese with English summary, p. 45.] *Jour. Oriental Med.* 14(5): 1931.—Rabbits (no. not stated) were irradiated for 1 hr. each with 100, 50, 20 and 10 mgm. Ra and examined 24, 48, 72 and 120 hrs. afterward. Weight and general condition showed no change. Erythrocytes and blood pigment were markedly decreased, in proportion to the quantity of irradiation, at 24 and 48 hrs. but began to increase at 72 hrs. and returned to normal in 120 hrs. Leucocytes increased at 24-48 hrs., then suddenly fell below average, generally returning to normal in 120 hrs., the changes bearing no fixed relation to quantity of irradiation.

315. **SCHAAL, G., M. A. GRUSCHETZKAJA, und E. J. ZWILICHOWSKAJA. Beitrag zur biologischen Wirkung der Röntgenstrahlen. (Wirkung der Röntgenstrahlen auf die Elektrolyte Kalium und Kalzium im Blutserum des Menschen.)** *Strahlentherapie* 40(1): 111-124. 1931.—K-Ca determinations (54) were made on 20 patients before and 24 hrs. after irradiation with varying doses of x-rays and, in some, before and after each series of irradiations. A shift in the K/Ca quotient occurred which appeared to be dependent on the interval between irradiation and examination; during the first few days after irradiation it favored K, later Ca. Apparently clinical phenomena (x-ray intoxication, early reaction, variations in leucocyte count, analgesic action) might be explained by this shift in the K/Ca quotient.

316. **SCHLIEPHAKE, ERWIN. Über die Möglichkeit gesundheitlicher Schädigungen durch elektrische Wellen.** *Gesundheits-Ingenieur* 52(46): 798-800. 1929.—In a receiving circuit inductively coupled to a short wave transmitter small animals are rapidly killed in the intense electric field between the plates of the receiving circuit condenser. Contact with the plates of the condenser results in sparking which causes a cutaneous burn. This is less injurious than a deep burn due to excessive radiation which may result in internal necrosis. Due to the large heat capacity of the human body there is small danger of overheating near a short wave transmitter of 100 watts since only a small fraction of the radiant energy is received by the body and converted into heat.—*A. Hemingway.*

317. **SICILIANO, L., e C. BANCI-BUONAMICI. Studi sul midollo osseo sotto l'azione dei raggi X. [The bone marrow under the action of x-rays.]** *Arch. Radiol.* 6(6): 1108-1136. 2 pl. (col.) 1930.—Of 19 rabbits a single limb or only the ears were irradiated in some, the rest of the body being protected; in others a single limb was protected, the rest of the body being irradiated. Doses of 5, 9, or 19 H, were given once or repeatedly with intervals of several days. Besides the modifications produced in the bone marrow under the direct influence of the x-rays, the bone marrow not irradiated showed degenerative modifications in histologic structure and in the medullary elements. The megacaryocytes showed important nuclear alterations; the % of immature erythrocytes was perceptibly increased, and the reds were increased in comparison to the whites; the polymorphonuclears were in general reduced in number except when the doses were very small. When the circulation of the irradiated limb was interrupted during irradiation, the results both to the irradiated bone marrow and that at a distance were reduced, probably because of the smaller quantity of toxic products put into circulation.

318. **SPEAR, F. G. The delayed lethal effect of radium on tissue cultures in vitro. Comparison of continuous and spaced radiation.** *Proc. Roy. Soc.* [*London*] *B* 108(756): 190-195. 1931.—Cultures of the 8-9 day choroid or sclerotic of fowl embryos were subjected to continuous (6 hr.) or to discontinuous (1 hr. per day on 6 consecutive days) irradiation (γ rays) from 300 mgm. radium (as sulphate) at 0.5 cm. distance. To test effects, sub-cultures were made every 48 hrs. after irradiation. In both cases, manifestation of the lethal effect was delayed. The 18 cultures given continuous irradiation survived to the 4th-8th explantation after irradiation, the average being 6.1 subcultivations; those given discontinuous irradiation (20

cultures) also survived to the 4th-8th, the average being 6.0; the difference seems not significant.

319. **VECCHI, GIUSEPPE.** Esperimenti di iniezioni endovenose di polvere di carbone e di bleu trypan carichi di Radon in ratti con tumori. [Intravenous administration of coal dust and trypan blue loaded with radon to rats with tumors.] *Arch. Sci. Med.* 54(12): 844-850. 1 fig. 1930.—In the majority of cases the tumor did not develop or regressed when developed.—*M. Comel.*

320. **VECCHI, GIUSEPPE, e SERGIO TENEFF.** Alterazioni morfologiche del sangue di ratti trattati con iniezioni endovenose di Radon. [Morphological alterations of blood in rats treated with intravenous administration of radon.] *Arch. Sci. Med.* 54(12): 851-860. 3 fig. 1930.—A noticeable diminution of erythrocytes and leucocytes was observed.—*M. Comel.*

321. **WALTERS, O. M., B. J. ANSON, and A. C. IVY.** The effect of x-rays on the thyroid and parathyroid glands. *Radiology* 16(1): 52-58. 7 fig. 1931.—Four experiments each using 2 dogs were made: (1) 3 series of irradiations (a series consisted of 4 doses of 385 r units at 7-14 day intervals) with 4 mos. between the 1st two and 1 mo. between 2nd two, the animals observed 9 mos.; (2) 1 series, thyroid examined 4 mos. later; (3) 2 series, 3 mos. apart, one thyroid removed 2 mos. later, the other 4 mos. later; (4) 3 series, 1 mo. between first two, 3 mos. between second two; 1 thyroid removed between 2nd and 3rd series. The thyroid was hyperplastic in 4 dogs in experiments 1, 2, and 4 and the capsule somewhat thickened in 2 dogs in which the skin was burned. Definite hyperplasia occurred in the parathyroids; in those dogs in which some mos. elapsed after treatment an increase in connective tissue was found. In spite of the hyperplasia a gradual, slight decrease occurred in blood Ca.

322. **WINTZ, HERMANN.** Strahlenschäden an Hoden, Eierstock und Frucht. *Monatsschr. Geburtsh. u. Gynäkol.* 78(6): 428-449. 1928.—A review of the effects of x-rays on the testes, ovary and embryo. Effects on the testes comprise 3 groups: (1) degeneration of spermatogonia; (2) depopulation of seminal canal; and (3) destruction of interstitial cells. Groups 1 and 2 are capable of repair. The clinical result in group 3 is the same as in operative castration. Radiosensitivity of the interstitial cells is not safely known. Accumulations of small doses play an important rôle. A 34% erythema completely destroys ovulation and internal secretions of the ovary, and a condition similar to menopause develops. Temporary sterilization can be produced by 28% erythema. More reliable data are necessary to show definitely the effects of direct or especially indirect radiation on the human embryo. Malformations have been observed in several cases.—*K. W. Buchwald.*

Sperim.* 5(5): 697-700. 1930.—The esters of glycerol and cholesterol give negative results with Ciaccio's method after treatment with $K_2Cr_2O_7$. Lecithin and linoleic acids give positive result only if freshly prepared.—*M. Comel.*

329. **CIACCIO, C.** Azione della cromizzazione sui lipidi. II. Ricerche chimiche. [Chemical studies on the effects of $K_2Cr_2O_7$ on lipids.] *Boll. Soc. Ital. Biol. Sperim.* 5(5): 701-704. 1930.—With Ciaccio's method olein is completely removed by solvents after treatment with $K_2Cr_2O_7$. The phospholipids are rendered completely or almost completely insoluble; no evidence of splitting was noted following $K_2Cr_2O_7$ treatment.—*M. Comel.*

330. **FØLLING, A.** Methods for the determination of total fixed base, sodium and potassium in urine. *Skand. Arch. Physiol.* 61(1/3): 27-31. 1931.—Micromethods for the determination of total base and for Na and K in urine are described. The total base and the combined Na and K are determined by a benzidine method; the Na is determined separately through an urano-zinc-sodium compound, and the K found by difference.—*Author's summary.*

331. **FOSBINDER, RUSSELL J.** A vacuum tube potentiometer for the determination of the true E.M.F. of a high resistance cell. *Jour. Cancer Res.* 14(4): 523. 1930.—Abstract.

332. **FOSBINDER, RUSSELL J., and JANETTA SCHOONOVER.** An improved method of measuring glass electrode potentials. *Jour. Biol. Chem.* 88(2) 605-614. 5 fig. 1930.—A single tube (UX-222 screen grid) direct current amplifier, capable of measuring the true e.m.f. of a high resistance cell with an accuracy of 0.0001 V. is described. The grid has a precision variable bias, which may be so adjusted that at "balance" no current flows through the cell. Results obtained with a series of phosphate buffers indicate that the glass and

hydrogen electrodes are comparable in accuracy. A description is given of a constant temperature cell with which the pH of 0.05 cc. of fluid may be accurately determined.—*R. J. Fosbinder.*

333. FUJITA, AKIJI, und KOTARO OKAMOTO. Manometrische Messungsmethode des Blutzuckers. *Biochem. Zeitschr.* 225(4/6): 368-385. 2 fig. 1930.—First the total reduction is determined, and then the residual reduction after yeast fermentation. The true fermentable sugar is the difference between the two results. This method depends upon the quantitative formation of N from K-ferricyanide. Added glucose was quantitatively recovered. The values secured corresponded well with those obtained by the Hagedorn-Jensen method. The influence of other reducing substances than glucose is somewhat less by our method. Anticoagulants such as citrates and oxalates when used in ordinary quantities cause no trouble. A fresh pure culture of yeast is used for the determination of the residual reduction. By the addition of yeast (50 mgm. of dry substance to 1 cc. of blood at 30° C. for 30 min.) the blood sugar was completely removed. Thorough washing of the yeast is emphasized, and it is well to shake the yeast 1 hr. in a thermostat at 30° C. to avoid the production of reducing substances from the yeast itself. When the largest quantity of creatin, creatinine and uric acid which can be found in pathological blood is added and the true fermentable sugar is determined, the results are not vitiated.—*Authors' summary (transl. by E. G. Schmidt).*

334. GANASSINI, DOMENICO. Reazione cromatica della glicerina coi tiosolfati alcalini. [Chromatic reaction of glycerol with alkaline thiosulphates.] *Arch. Ist. Biochim. Ital.* 2(2): 239-242. 1930.—$Na_2S_2O_3$ added (as powder) to glycerol is dissolved with small heat production and gives a perfectly clear and colorless solution. If this solution is heated to boiling, it develops a sky-blue color which deepens to indigo-blue. The coloration is very unstable, and quickly disappears if the solution is cooled, giving a green and then a reddish color. When the boiling is prolonged the color becomes reddish brown. By the blue color reaction it is possible to detect the presence of glycerol as well as of thiosulphate.—*M. Comel.*

Med.* 114(4/5): 456-465. 1930.—The Hunt acetonitrile reaction is characteristic, but not specific, for thyroxin, thyreoglobulin, and the blood of hyperthyroid cases. In healthy individuals the results are negative. The reaction is brought about not directly by the thyroid substances but indirectly by secondary changes in the composition of the blood. The reaction is negative with urine, cerebrospinal fluid, and exudates.—*Author's summary (transl. by P. A. Katzman).*

336. HADEN, RUSSELL L. The technic of determination of the relative mass, the individual cell volume, and the volume index of the erythrocytes of man. *Jour. Lab. & Clin. Med.* 15(8): 736-746. 1930.—Experiments are reported to determine the best method of estimating the volume relationship between the red corpuscles and plasma of men. An accurate determination of this relationship necessitates the employment of an isotonic anticoagulant and sufficient power and time of centrifugation to completely separate the cells from the plasma. A 1.4% solution of Na oxalate is isotonic with human blood. Centrifugation for 1 hr. at 2500 r.p.m. with radius of 10 cm. will completely separate erythrocytes from plasma. The relative mass of the erythrocytes is best determined by centrifuging in such a way, 10 c.c. of blood to which 2 c.c. of 1.4% Na oxalate has been added. The average red cell content of the blood of young men is 46 c.c. per 100 c.c. of blood, and of young women 41 c.c. Illustrative examples are given for the calculation of the volume index and the average individual cell volume.

[Determination of the phosphatid P_2O_5 for small amounts of serum by the gravimetric strychnin-molybdenum method.] *Biochem. Zeitschr.* 227(4/6): 334-339. 1930.

342. KOHLRAUSCH, W. Methodik zur quantitativen Bestimmung der Körperstoffe in vivo. *Arbeitsphysiologie* 2(1): 23-45. 1 fig. 1929.—The basal metabolism of 4 dogs was measured by the Douglas method, using either a mask or a canula. The protein content of the bodies was determined after killing. A constant relationship between the 2/3 power of the protein content and the basal metabolism was found, viz., 2.3 calories per min. per 1000 sq. cm. The glycogen was assumed as 0.5% of the body weight, and water as 67.5%, confirmed by analysis. The volumes of the animals both living and dead were determined by a pneumatic chamber. The soluble salts were assumed to be 0.8% of the body fluids. The weight of the fat and ash (insoluble salts of bone) together equals the difference between the whole body weight and the sum of the weights of protein, water, glycogen, and soluble salts. The volume of fat and ash together equals the difference between the total volume of the body and the sum of the volumes of protein, glycogen, water, and soluble salts. The specific gravities of fat and ash are known. From the weight of fat and ash, the volume of fat and ash, and their specific gravities, 4 equations with 4 unknowns are derivable, and the solutions of these give the weights of fat and ash respectively. A set of values for 4 dogs derived by calculation from the basal metabolism, the volumes, the body weights, and assumed percentages for water, glycogen, and soluble salts agree well with values derived by analysis of the cadavers.—*T. M. Carpenter.*

344. MAZZA, F. P., e A. ROSSI. Un micrometodo per la determinazione del potassio con particolare riguardo ai liquidi biologici. [A micro method for determination of potassium.] *Arch. Sci. Biol.* 13(3/4): 466-472. 1929.—From the serum or other organic liquid (1 cc.), placed in a centrifuge tube, K is precipitated with sodium cobalt-nitrite, and the tube centrifuged. The supernatant fluid is removed, the precipitate is washed with $NaNO_3$ and again centrifuged three times. Now $NaHCO_3$ is added, the mixture heated under gentle agitation, then cooled, mixed with permanganate and titrated with ferrous sulphate. The method is simple, rapid, and easy, not even micro-burettes being required.—*A. Jappelli.*

345. MICHAELIS, OSCAR. Die Brauchbarkeit der histochemischen Methoden des Goldnachweises. *Biochem. Zeitschr.* 225(4/6): 478-488. 1930.—Organs of 2 rabbits treated with organic or inorganic Au preparations were fixed in various ways and examined according to

the methods of Christeller and Borchardt.—Fixation in a mixture of $SnCl_2$ and formalin (Christeller) offers no advantage over ordinary formalin fixation. In the modification herein presented, alcohol fixation gives the same result. The Christeller $SnCl_2$ test does not give good Au ppts. with the org. Au preparation (Lopion). The Christeller modification (acidification with HNO_3) gives better results but is technically deficient (brittleness, sediments). Likewise the Borchardt $AgNO_3$ method is not always satisfactory. Both methods are modified: In the Christeller procedure HCl is substituted for HNO_3 to acidify the $SnCl_2$. Thus interfering sediments are avoided and with any material or fixation, black ppts. are obtained, insol. in conc. acids, readily sol. in aqua regia. The same results are obtained with the Borchardt method modified by use of higher temp. for Au pptn. and high concn. of HNO_3 to dissolve interfering Ag ppts. The modified methods are equivalent and certain. —*Author's summary (transl. by W. A. Peabody).*

350. OKEY, RUTH. A micro method for the estimation of cholesterol by oxidation of the digitonide. *Jour. Biol. Chem.* 88(1): 367-379. 1930.—A micro procedure for the determination of free and total cholesterol by oxidation of the digitonide with silver chromate-sulfuric acid and subsequent titration of the excess dichromate with thiosulfate is described. Cholesterol is altered by the ordinary saponification procedures in such a way that it is no longer quantitatively precipitated by digitonin. A study of the conditions under which a synthetically prepared ester of cholesterol may be saponified with minimal alteration in the cholesterol has been made and a special procedure for saponification of blood and tissue extracts which conforms to these conditions has been evolved. Attention is called to the fact that, because of this decomposition of cholesterol during saponification, many estimations of cholesterol by precipitation as digitonide from unsaponifiable matter have given inaccurate results.—*Author's summary.*

351. ORIAS, O. Dosaje de la hemoglobina sanguínea. Exámen de los métodos de Sahli-Leitz, Hellige, Newcomer y Bürker. [Estimation of hemoglobin in blood.] *Rev. Soc. Argentina Biol.* 6(5/6): 363-384. 1930.—Critical study of methods using Van Slyke's gasometric as standard. The Sahli-Leitz and the Hellige methods give accurate values after calibrating the pipettes when Hb concentration is within the usual limits; when low Hb values are found 2 or 3 times the usual quantity of blood should be used as the error increases with low Hb concentration.—Newcomer's method is practical and accurate, with Hb values between 9 and 15% the mean probable error lies between 0.39 and 1.69%, rarely as much as 3%. Bürker's method gave figures in close agreement with Van Slyke's. It would be convenient to give figures always in gm. of Hb, if an arbitrary standard is used the value of 100% should be given in gm. Hb.—*J. T. Lewis.*

367. **BINET, LÉON, et HENRY CARDOT. Sur la survie de la tête isolée des poissons, avec ou sans perfusion.** *Jour. Physiol. et Pathol. Gén.* 27(2): 250-256. 1 fig. 1929.—The authors extended the study carried out by Kouliabko on fresh water ganoids, teleosts, and lampreys to the marine teleost, *Gobius*, with modifications in technic. The body was cut off directly behind a tight ligature encircling it just behind the pectoral fins. These fins were removed, the branchiae laid bare, and the aorta cannulated. Perfusion was started, the ligature cut, and the preparation bathed in running sea water. Isolated heads not perfused did not survive. Those perfused with sea water or half sea water did not survive. Perfusion with Ringers pH 7.4 containing $MgCl_2$ and NaH_2PO_4 survived 20 min. Adding glucose to this lengthened survival to 30 min. Urea in place of glucose had no favorable effect, but adding urea to the glucose-Ringer's gave the longest survivals, 1½ hrs. in 1 case. During glucose-Ringer or urea-glucose-Ringer perfusions respiration had considerable amplitude and showed normal phases and normal movements of the structures involved. The authors conclude that they were able to confirm Kouliabko's finding that perfusion methods are applicable to fish, and that glucose and probably urea have favorable effects.—*A. L. Hintze.*

371. **DEMUTH, FRITZ. Praktikum der Züchtung von Warmblütergewebe in vitro.** 116p. 49 fig. R. Müller & Steinicke: Munchen, 1929. Pr. 6M.—The technique of this laboratory book is based for the most part on the work of Carrel and A. Fischer, and covers the usual methods of obtaining blood plasma from the chicken and mammals together with the usual procedures of preparing plasma and various saline media. The technique of ordinary coverglass preparations and the Carrel flask method are taken up in considerable detail. There are short sections devoted to photo-micrography, to the measurements of growth, to chemical determinations, micro-manipulations, and so forth. There are many useful suggestions regarding instruments, solutions, and histological methods.—*W. H. Lewis.*

372. **FIROR, W. M. Experiments in cross circulation.** *Amer. Jour. Physiol.* 96(1): 146-152. 2 pl. 1931.—This paper describes the technic for crossing the circulating bloods of dogs by means of carotid-jugular anastomoses. The results of 40 experiments are given. In 2 instances the exchange of blood was maintained for 6½ days. The effects of cross-circulation upon the pulse rate, respiratory rate, temp., blood pressure, blood chemistry, and red blood cells were studied. Three sets of experiments closely related to the crossed carotid-jugular anastomoses are reported.—*Author's summary.*

373. **FLEISCH, ALFRED. Der Pulszeitschreiber; ein Apparat zur Aufzeichnung der zeitlichen Pulsintervalle als Ordinate. [The sphygmograph, an instrument for recording the time-pulse intervals as ordinates.]** *Zeitschr. Ges. Exp. Med.* 72(3/4): 384-400. 8 fig. 1930.—The mechanical principles of the new mechanism are described. It is reported accurate, measuring time intervals with an error of $\pm$ 0.004 second.

374. **FUCHS, HANS J. Einfaches Tierbrett.** *Zeitschr. f. Immunitätsforsch. u. Exp. Therap.* 65(5/6): 515-516. 1930.—A simple animal board is described.—*N. W. Larkum.*

375. **GIBBS, O. S. An artificial heart.** *Jour. Pharmacol. & Exp. Therapeut.* 38(2): 197-215. 5 fig. 1930.—Two rubber bellows with suitable inlet and outlet valves are inclosed in a brass box which contains warm water. The filling of the bellows with blood activates switches which cause the opening of an electric valve connected to a source of water pressure. The pressure squeezes and thus empties the bellows, when this occurs the valve is released and the water surrounding the bellows allowed to drain away. The slight suction thus obtained is utilized to fill the bellows which are connected with suitable cannulae to the auricles, to the pulmonary artery and to the systemic aorta. Owing to the small capacity of the instrument (20 cc.) it can be used directly without extra blood. Cats so treated may live for two to three hours. Drug reactions are shown and attention is drawn to the fact that the instrument is another step in the analysis of circulatory problems including that of shock.—*O. S. Gibbs.*

Med.* 72(3/4): 522-536. 46 fig. 1930.—Description of procedure in the 3-canula operation on the portal, hepatic and renal veins, angiostomy of the venae pancreatico-duodenalis, of the V. lumbalo-suprarenalis and of the vena lienalis.

386. RANKER, EMERY R. Apparatus and method for obtaining sterile filtrates of biological fluids. *Phytopathology* 20(7): 569-573. 2 fig. 1930.—This apparatus consists of a Chamberland-Pasteur B filter connected to the T-shape side arm of the glass tube enclosing a W Berkefeld filter through which a second filtration is accomplished. The sterile filtrate thus continues through the system and is collected in a flask of convenient size. Details of the construction are given.—*W. A. Whitney.*

387. ROESE, H. F. Methoden zum Studien der Physiologie und Pharmakologie des künstlich durchbluteten Säugetierdarmes. *Pflüger's Arch. Ges. Physiol.* 226(2): 171-183. 2 fig. 1930.—Four methods are described for use in dogs, using dog's blood as perfusion fluid. (1) Simple perfusion, using hydrostatic pressure, of an excised strip of intestine causing marked fluctuations in vascular tonus, severe damage to intestinal epithelium, and massive transudation into lumen of bowel, prevent any useful application. (2) Using a denervated heart-lung-intestine preparation with perfusion the flow remains constant and transudation is avoided if perfusion pressure is kept low but intestinal epithelium is damaged severely. (3) By transplantation of the intestine into carotid-jugular circulation of another dog, using Payr's tubes so as to render defibrination unnecessary, intestinal epithelium is also damaged, showing that the toxic agency is not absence of a hormone from blood or a product of defibrination. (4) An innervated heart-lung-intestine preparation damaged the epithelium less than any of the other methods, indicating that the celiac plexus exerts a tonic influence upon intestinal capillaries. The applicability and limitations of each method are discussed.—*C. F. Schmidt.*

NUTRITION AND DIET

395. **SIHVONEN, KERTTU.** Zur Kenntnis des Nährwertes von Abfällen bei der Konservenfabrikation von Schweinefleisch. *Skand. Arch. Physiol.* 59(5/6): 231-242. 1930.—Skin and bones of pork were first analyzed. The skin gave 60.2% dry substance, 29.1% protein, 25% fat, 6.1% ash and 3518 calories per kgm. In 3 lots of bones the dry substance varied from 5.9% to 16.4%, the protein from 1.6% to 2.6%, the fat from 3.4% to 13.5%, the ash from 0.3% to 0.6%, and the calories from 406 to 1362. Next the skin, in soup and separately, was fed to 2 human subjects, and the feces analyzed, both after a pork-skin meal and after a meal without the pork-skin. The average total resorption for the 2 subjects was 97.5%, dry substance 96.6%, protein 94.9%, fat 98.7% and ash 96.6%, indicating that pork-skin is very suitable for human consumption.

396. **SUPPLEE, G. C., O. D. DOW, G. E. FLANIGAN, and O. J. KAHLENBERG.** A comparative study of liquid and dry milk as anemia-producing diets. *Jour. Nutrition* 2(5): 451-469. 1 pl., 14 fig. 1930.—Nutritional anemia in rats was produced by feeding natural fluid milk, milk boiled 2 min., and reconstituted spray process milk powder. Reconstituted dry milk, having the same Cu content as the milk from which it was prepared but with increased Fe content resulting from contact with drying cylinders, prevented the development of "milk anemia." It also improved anemic conditions resulting from a natural milk diet, as shown by physical condition, blood count, and hemoglobin content. Where the Fe content of the reconstituted milk was 4 times that of normal milk, a normal hemoglobin and blood count was maintained. Milk dried on iron cylinders apparently acquires measurable anti-anemic properties.—*E. L. Batchelder.*

397. **SUZUKI, BUNSUKE, and UZO NISHIMOTO.** The kephalins of soy bean. *Proc. Imp. Acad.* [*Tokyo*] 6(7): 262-265. 1930.—Details of a chemical investigation are given. Two β kephalins, linoleo-stearo-β-kephalin and linoleno-stearo-β-kephalin, were isolated.

398. **VISCO, S.** Osservazioni sullo sviluppo di ratti alimentati con frumenti duri e di ratti alimentati con frumenti teneri. Relazione tra peso iniziale dell'animale e valore nutritivo dell'alimento. I e II. [Influence of various kinds of wheat upon growth of rats. Relation between initial weight of the animals and nutritive value of food. I and II.] *Boll. Soc. Ital. Biol. Sperim.* 5(2): 198-204. 3 fig.; 204-209. 1930.—No difference in the nutritive value was observed between the hard and the soft wheat. During development of the animal the nutritive value of a given food may be greater or less, according to the degree of development of the animal itself.—*M. Comel.*

399. **WETZEL, GEORG.** Wachstum und Widerstandsfähigkeit der Ratte bei pflanzlicher und bei tierischer Nahrung. *Zeitschr. Ges. Anat. Abt. I.* 92(6): 802-826. 5 fig. 1930.—Studies on rats (apparently about 100) lead to the conclusion that flesh food produces a more rapid growth, a livelier condition, an earlier sexual development, greater resistance to certain noxious influences, and a stronger development of the lymphoid tissue in the intestine, than does vegetable food.

400. **WILLI, HEINRICH.** Vegetabile Rohkost und animalische Kost im Selbstversuch. *Deutsches Arch. Klin. Med.* 168(3/4): 156-175. 1930.—A raw vegetable diet, rich in calories and very poor in NaCl, which was used rigorously for 10 weeks proved unsatisfactory. A diet rich in protein which was mainly animal, taken for 14 days, was equally poor. The body weight fell during the raw diet 2750 gm., rose during the animal diet 1600 gm. The blood-pressure fell during the raw diet from 122/65 mm. Hg to 90/45 mm. Hg. On the animal diet it showed no great variations. During raw diet there was a temporary hypochromic anemia, leucocytes increased somewhat and a monocytosis of 15% appeared. During protein diet no important hematological changes were noticed. Balance experiments showed that the absorption from the intestine was incomparably better with the protein-rich diet than with the raw diet: but at the same time the intermediary metabolism rose, the formation and renal-excretion of waste increased. Basal metabolism showed no abnormal variations. The mineral balance was positive during the diet low in salt, despite considerable loss in the stools. The Cl requirement was met with a very small allowance, avoiding hypochloremic symptoms. When a large amount of NaCl was fed, it was not excreted at once, as it is by the child, but in 4 days. K fed in large amounts was not stored, but excreted. Acid-base studies showed a relation between the pH and the excretion of organic acids. With the raw diet the urine was strongly alkaline, the excretion of organic acids rose notably, especially when the system was overloaded with K acetate. Fanconi's conception, that the increased excretion of organic acids under great excess of bases is a reserve mechanism similar to that of NH_3 under acid conditions, is supported by these observations. The excretion of organic acids follows the N excretion, as Brock observed, only with a mixed diet, when pH varies between 6 and 7. As soon as pH becomes alkaline, the N curve and the organic acid curve separate widely. The NH_3 and acid coefficients then behave reciprocally. The chemical composition of the blood shows a remarkable constancy with each kind of diet.—*Author's summary (transl. by M. H. Keith).*

ENERGY METABOLISM

401. **ALWALL, NILS, and AXEL HÖJER.** The influence of lemon juice on the tissue respiration of normal and scorbutic guinea-pigs. II. *Skand. Arch. Physiol.* 59(3/4): 89-91. 1930.—The retarding effect of inactivated lemon juice on the tissue respiration by experiments with Thunberg's methylene-blue method (Höjer) is due to a precipitate formed during the autoclaving. The fact that the intensifying effect of the raw juice remains even after its inactivation, if only the precipitate is removed, makes it probable that this intensifying effect is not an antiscorbutic one. Instead it is probably to be regarded as a "donator" effect.—*Authors' summary.*

402. **APPEL, K. E., and C. B. FARR.** The specific dynamic action of protein in relation to mental disease. *Jour. Nervous and Ment. Dis.* 70(1): 43-50. 1929.—In 28 cases—26 with miscellaneous psychoses and neuroses—basal metabolism tests and estimations of the specific dynamic action of protein were made. A subnormal specific dynamic action was found in 5 patients, 1 of early uncomplicated dementia precox, the rest with toxic or nutritional factors. Other cases of dementia

precox and of nutritional disturbance showed normal reactions. Fischer has reported characteristic disturbances of metabolism (specific dynamic action) in schizophrenia; others have found similar changes in endocrine and nutritional disorders. Our findings, while inconclusive, do not stress nutritional disorders.—*From authors' summary and conclusions.*

403. BENNET-CLARK, T. A. A method of investigating gas exchanges of living tissues. *Nature [London]* 125(3152): 492-493. 1 fig. 1930.—The principle of the method is as follows: a gas mixture circulates in a closed system over the material under investigation, and through a solution of $Ba(OH)_2$. Since CO_2 is absorbed, there is a reduction in volume of the gas mixture due to the absorption of O by the tissue. This causes the level of liquid to rise in a manometer placed between the closed respiration system and another closed volume of air (the compensator). The liquid is an electrolyte, and when it rises a short distance (about 1 mm.), it makes contact with an electrode from which O begins to be evolved; further decrease in volume of the system due to absorption of O is thus prevented by this automatic electrolytic addition of O which takes place at the same rate as that at which O is absorbed by the tissue. This rate is measured by measuring the current used in the course of the electrolysis by either finding the volume of H or weight of Ag simultaneously set free. The rate of CO_2 emission of the tissue is found by observing the change in electrical resistance of the Ba $(OH)_2$ solution, which rapidly increases owing to the conversion of the hydroxide into insoluble $BaCO_3$.

405. CHAMBERS, WILLIAM H., and GRAHAM LUSK. Animal calorimetry. Thirty-ninth paper. Specific dynamic action in the normal and phlorhizinized dog. *Jour. Biol. Chem.* 85(2). 611-626. 1930.—In the dog the specific dynamic action of glycine, as measured by its calorigenic action, is dependent on the amount administered and is independent of the size of the animal which has received the glycine. Glutamic acid given to the normal or diabetic dog exerts no specific dynamic action. Fat given in small quantity to the normal dog shows a slight specific dynamic effect and may show none in the diabetic dog. The specific dynamic action of meat appears to be the same in the normal as in the diabetic dog. Just as in the case of a fasting dog, which in running maintains the reaction glycogen-lactic acid-glycogen at the expense of fat which is oxidized, so the fuel which is necessary to drive certain of the cleavage products of protein into glucose in diabetes may be fat. The fuel needed for this purpose wholly or in part constitutes the extra heat of the specific dynamic action of protein. This analysis accords with the ideas of Aubel, of Meyerhof, and of Adams.—*Authors' summary.*

406. CHIATELLINO, A. Il ricambio gassoso della ghiandola tiroide. [Gaseous exchange of the thyroid.] *Arch. di Sci. Biol.* 14(1): 11-25. 1 fig. 1929.—During morphine-chloral narcosis, blood supply to the thyroid is smaller than in curarised dogs, the consumption of O by the gland is lowered, but the CO_2 output is raised. Among all organs, of which O consumption by blood gas analysis was determined, thyroid appears to have a more active gaseous exchange and a much greater blood supply.—*A. Jappelli.*

407. COBET, R., und T. v. HAEBLER. Über den Einfluss der Kohlensäuregasbäder auf den Menschen. *Zeitschr. Klin. Med.* 112(1/2): 134-149. 1 fig. 1929.—In cold CO_2 baths the blood flow through the skin was increased. There was not enough CO_2 absorbed by the dry skin to influence the gas metabolism significantly. In gas baths at 38-50° C. there was hyperemia of the skin, and a remarkable increase in sweat secretion. The internal temperature of the body could therefore either rise or fall, depending on the length of time the body was immersed in CO_2. The O consumption was increased only a little, and sometimes even decreased. A warm CO_2 gas bath was really a special form of sweat bath. Damp, sweating skin could absorb more CO_2 than dry skin. The respiratory quotient rose during the bath; after the bath it gradually fell to normal. Alveolar CO_2 tension was generally increased; it never decreased. The CO_2 absorbed by the skin of the whole body surface was about 100-150 cc. per min. CO_2 stimulated the respiratory center, thus increasing respiratory rate and total volume.

408. COMEL, M. Azione dell'acqua termale sul ricambio gassoso dei tessuti. [Action of thermal water on gaseous metabolism of the tissues.] *Biochim. e Terap. Sperim.* 16(12): 621-627. 1929.—The author used reduction of m-dinitrobenzene as an indicator of tissue metabolism. The thermal water he used was slightly radioactive and had a pH of 7.5. Frog muscle was used as the experimental material. Thermal water decreased tissue metabolism.

409. CONKLIN, CLAIRE J., and J. F. McCLENDON. The basal metabolic rate in relation to the menstrual cycle. *Arch. Internal Med.* 45(1): 125-135. 1930.—About 1000 determinations of basal metabolic rates of women were made and then a selection was made of 10 individuals who showed a very regular respiratory rhythm. On each of these a basal metabolic rate was done once a day for a month or more. The daily variations are plotted together with the menstrual history, and then the determinations are divided into those during the menstrual period and the intermenstrual period, which was divided into 3 equal parts, post-menstrual, inter-menstrual and pre-menstrual. The rates were averaged for each period and the probable errors calculated. There is considerable variation in individual cases but averages of the 4 groups were made and there was a rise from the post-menstrual to the pre-menstrual of 1.28 cal. per sq. m. per hr. The probable error was 0.199—in other words, the rise in metabolic rate was more than 6 times the probable error. It was shown by Frank that the ovarian hormone in the blood rises during this period of rise in basal metabolic rate.—*J. F. McClendon.*

410. EISMAYER, G., und H. QUINCKE. Sauerstoffverbrauch, Kohlensäure- und Milchsäureabgabe des Herzens bei verschiedener Arbeit. III. Mitteilung (Stoffwechseluntersuchungen am Kaltblüterherzen). *Zeitschr. Biol.* 89(6): 523-535. 4 fig. 1930.—Strongly auxotonic work increases the O consumption of the frog's heart. A more rapid rate increases it proportionally to the work of a single beat. In protracted experiments the O consumption sharply decreases before the heart becomes hypodynamic. The addition of sugar restores it to the former level. With slight variations the CO_2 liberation runs parallel, with a respiratory quotient of 0.5 to 0.9. During aerobic work lactic acid appears in the fluid. More lactic acid appears during work with low pressures than with higher pressures of filling. More lactic acid appears under anaerobic conditions. Oxygen consumption furnishes no indication of the efficiency of work of the heart.—*G. Eismayer (transl. by R. C. Corley).*

411. EISMAYER, GOTTFRIED, und HERMANN QUINCKE. Ueber den Einfluss des Sauerstoffangebotes und des Insulins auf den Gaswechsel des Herzens. (Stoffwechseluntersuchungen am Kaltblüterherzen. IV. Mitteilung). *Zeitschr. Biol.* 90(1): 57-62. 1 fig. 1930.—By previously described methods the O-consumption of the frog heart was found to be the same whether the nutrient solution contained 8 or 16 vol. % of O. Below 8 vol. % it falls at first slowly, then always more rapidly, without the mechanical work of the heart being impaired. Addition of insulin in small amounts to the nutrient solution does not affect the working-power and the O-consumption. Larger amounts of insulin lead to a reduction of O-consumption, and to an increase of the respiratory quotient. The working-power of the heart was reduced. The change in metabolism precedes the injury of the working-power.—*G. Eismayer (transl. by R. H. M'Gonigle).*

412. FLEISCHMANN, WALTER. Beiträge zur Physiologie der Gewebsatmung nach Untersuchungen an Win-

terschläfern. *Pflüger's Arch. Ges. Physiol.* 222(4): 541-547. 1 fig. 1929.—The study of liver tissues from hibernating animals, according to the method of Warburg, shows that O-consumption is entirely dependent upon temperature and equally whether the tissue is from a hibernating or a waking animal. This dependence on temperature obtains for tissues of hibernating and also other mammals. The brown fat tissue, in contrast to the white, shows pronounced O-consumption. *W. Fleischmann (transl. by H. S. Hopkins).*

413. FRAPS, M. Studies on respiration and glycolysis in Planaria. I. Methods and certain basic factors in respiration. *Physiol. Zool.* 3(2): 242-270. 10 fig. 1930.—The manometric method of Warburg has been modified for the measurement of respiratory and glycolytic metabolism in Planaria. Improvements and modifications of apparatus include the use of sloping manometer gauges, complete immersion of entire gas volumes in the constant-temperature bath, the elimination of barometric fluctuations, and the use of readily interchangeable chambers. Concentrations of artificial media based on the salt content of spring waters are given for Planaria sp. The Ca : K ratio is relatively high. Relatively high concentrations of $NaHCO_3$ exert an initial depression on the rate of O consumption. This effect is of short duration (ca. two hours for 0.01M $NaHCO_3$), and is followed by an increase in the rate of O consumption slightly above that found in bicarbonate-free solutions. The rate of O consumption in atmospheres containing from 0.9 to 97 vols. % O has been measured. Oxygen tensions below ca. 15 vols. % act to limit the rate of O consumption. The present paper is considered preliminary to others which will follow on the quantitative measurement of energy exchange reactions in several forms of lower organisms.—*Author (courtesy Wistar Bibl. Serv.).*

414. FRASER, A. C., and B. P. WIESNER. Variations of the rest metabolism of the rat in relation to the sex cycle. *Proc. Roy. Soc. Edinburgh* 50(1): 1-7. 1929-30.—The CO_2 output of resting female rats at 37°C. varied from 9 to 24 mgm. per min. per kgm. The highest output nearly always occurred from 12 to 24 hrs. after full estrus, as indicated by complete cornification, while low points fell between the estrous stages. CO_2 output for ovariectomized rats ranged from 6 to 8 mgm. and was raised only slightly by injection of ovarian or placental extracts which produced full cornification. The increase in metabolism is therefore not ascribed to a delayed effect of estrin, but may be due to some other substance produced at the time of rupture of the follicles.—*M. Dann.*

415. FREW, J. G. H. Studies in the metabolism of insect metamorphosis. *British Jour. Exp. Biol.* 6(3): 205-218. 7 fig. 1929.—Respiratory quotient is very low (frequently below 0.6) during the pupal period. It is probable therefore that all glucose is not used up in respiration but is used in the building-up of imaginal tissue substance. Synthesis of glucose continues throughout the pupal period, but while during the earlier part glucose is derived from protein, in latter part it may be derived from fat. The respiration curve shows a gradual fall during the early pupal stage and a gradual rise during the latter. No sex difference could be detected.—*F. A. E. Crew.*

416. GIAJA, J. Les substitutions alimentaires dans le métabolisme de sommet. [French résumé] Глас (*Glas Srpska Kraljevska Akademija.*) 1926(122): 57-60. 1926.—The question of the influence of the food on summit metabolism is submitted. Will this be proportional to the value of the food, or the available reserve which the organism disposes of, or will its value vary as the basal metabolism? Some experiments favor this second possibility. Particularly in starvation one sees the summit metabolism increase at the moment the fats have disappeared, and the protein consumption increases. The specific dynamic action therefore makes itself felt equally in the summit metabolism.—*J. Giaja (transl. by R. H. M'Gonigle).*

417. GIAJA, J., et S. GELINEO. L'hypothermie et la thermogenèse. *Arch. Internat. Physiol.* 32(3): 237-250. 1930.—Rats were placed in metal boxes, which were chilled by a freezing mixture, and, at the temperature desired, were placed in a respiratory chamber; 5 experiments are reported. As long as the body temperature of the rat, reduced by external cold, is above 20°, O consumption is raised, comparably with its maximum consumption defined by peak metabolism. It is only when the temperature has fallen below about 20° that consumption decreases and thermic accommodation is overcome. While the temperature of the rat is falling under the influence of external cold, its O consumption does not noticeably vary, so long as hypothermia does not reach the limit which has been indicated. When the rat in hypothermia "a frigore" is suddenly placed at its ordinary thermic neutrality (about 30°), its O consumption diminishes during the re-warming, i.e., its consumption is higher by the degree that its hypothermia is lower than the indicated limit. Its temperature having again become normal, consumption in general still remains higher than it was before the exposure of the animal to cold. Hypothermia alone, without the influence of external cold, while augmenting calorification, cannot make it reach the maximal value which is attained in peak metabolism. These facts, with others already known, argue in favor of a stimulating action of hypothermia on heat production. Lowering of the temperature of the homeothermic animal, while stimulating thermogenesis, at the same time, according to biologic law, depresses its heat-producing apparatus. Thus thermogenesis of the homeothermic animal in hypothermia at any given moment is the result of the conflict of 3 factors, which are: external cold, internal cold and the lowered temperature of the heat-producing apparatus, the first 2 having a stimulating action, the last a depressing action on heat-production.—*Authors' summary (transl.).*

418. HILL, A. V. The rôle of oxidation in maintaining the dynamic equilibria of life. 24p. Oxford University Press: New York, 1929. Pr. 35c.—All changes associated with life involve a decrease in the free energy and an increase in the entropy of the physico-chemical system in which they occur. The free energy of the combination of O with foodstuffs renders the activities of life possible. While the above statements seem certain in the case of the animal cell, a more precise description of the rôle of oxidation is not known except in the case of the muscle cell; here the anaerobic breakdown supplies the energy of contraction, while oxidation provides the means by which the chemical reactions of contraction are reversed. The extra oxidation which follows muscular activity is the oxidation of some carbohydrate in the muscle which supplies the heat necessary for the recovery reaction: lactate + heat $\rightleftarrows$ glycogen. This is prevented by O-want, or even if O is present, by a trace of cyanide. With other organs and cells, this carbohydrate-lactic acid mechanism does not generally obtain. In the case of the non-medullated nerve of the Maia, measurements of the action potentials and injury potentials in presence of O and N show that oxidation is concerned in the maintenance of the potential difference across the boundary of the cell, i.e., in the recharging of the battery without which the nerve cannot transmit its impulses. This conclusion is verified by observations on the heat production or O consumed after nerve activity. H. finds a linear relation between the "resting heat rate" after any stage of stimulation and the total amount of heat liberated by stimuli applied to the muscle, and since the amount of energy liberated in an anaerobic stimulation measures the amount of lactic acid produced, which, in turn, is proportional to the degree of O-lack of the tissue involved, he concludes that there is a linear relation between this O-lack and the rate of some chemical breakdown or disintegration and that, in some way, O inhibits chemical disintegration. The process of lactic acid formation or of increasing O-want leads ultimately to the same state of chemical disintegration as does activity induced by stimulation.—*V. G. Lava.*

419. **HITCHCOCK, F. A., and FRANCES R. WARDWELL.** Cyclic variations in the basal metabolic rate of women. *Jour. Nutrition* 2(2): 203-215. 1 fig. 1929.—Experiments on 20 women, using the Benedict-Roth-Collins apparatus with kymograph attached, showed a strong tendency toward lower metabolic rate during the menstrual period and a 2nd low point about the middle of the intermenstrual period. A seasonal variation was observed showing the lowest metabolic rate in winter or spring and the highest in summer or autumn.—*E. L. Batchelder.*

420. **JORES, A.** Perspiratio insensibilis. I. *Zeitschr. Ges. Exp. Med.* 71(1/2): 170-185. 2 fig. 1930.—The bed-balance apparatus and method of estimating insensible perspiration described by Benedict were used in these studies. The parallelism between basal metabolism and insensible perspiration was complete, during rise and fall of basal metabolism, in exercise and in fever. The average absolute value of loss of water through the skin is about 200 gm. in 24 hrs. per square meter of body surface. In the night an increase of insensible perspiration took place, apparently paralleling depth of sleep.

421. **KLEIBER, M.** Wie und mit welcher Genauigkeit kann man die Schwankungen der Respirationsintensität ohne Tracheotomie oder Mundstück bestimmen. *Pflüger's Arch. Ges. Physiol.* 220(1/6): 599-605. 1 fig. 1928.—A formula is given allowing the calculation of the intensity of the respiratory exchange from the analysis of gas samples taken from an open-air circuit respiration apparatus.—*M. Kleiber.*

422. **KOMMERELL, BURKHARD.** Über den Einfluss von Schilddrüsendarreichung auf den Eiweiss und Fettstoffwechsel. *Biochem. Zeitschr.* 208(1/3): 112-126. 8 fig. 1929.—Experiments were made on fasting dogs with and without thyroid feeding. The gaseous metabolism was determined by the Douglas bag method. A modification of the Haldane gas analysis apparatus is presented. The N balance showed that the N loss in starvation was increased twofold under thyroid administration. The increase in basal metabolism amounted to 30%. Of this increase 31.3% was due to protein combustion and 68.7% to fat combustion.—*B. Kommerell (transl. by W. S. Root).*

423. **LEVINE, S. Z., and ELEANOR MARPLES.** The insensible perspiration in infancy and in childhood. III. Basal metabolism and basal insensible perspiration of the normal infant: a statistical study of reliability and of correlation. *Amer. Jour. Dis. Children* 40(2): 269-284. 1930.—A statistical study was made of the published data responsible for the standards at present available for the basal metabolism and basal insensible perspiration of normal infants. A similar statistical and experimental study was also made of the correlation between the 2 variables in simultaneous calorimetric measurements as well as in independent measurements with the respiration chamber and balance, respectively. The results verify, by statistical methods, the validity of the tentative standards recently proposed for the basal insensible perspiration of normal infants and indicate that they compare favorably in reliability with the generally accepted standards for the basal metabolism of these subjects. The evidence, statistical and experimental, also establishes a high positive correlation between the physiologic mechanisms of heat production and insensible perspiration in the human subject, whether measured simultaneously in the respiration chamber or independently with the balance and respiration chamber. Evidence of correlation between the 2 variables in independent measurements is thus far limited to infants and adults. The demonstration of causal relationship in infants between the 2 mechanisms was utilized to extend to these subjects the method proposed by Benedict and Root for predicting the probable metabolism of adults from their insensible perspiration measured with a balance. This method gave satisfactory results in the small number of infants thus far studied. The latter included several subjects with an abnormal respiratory exchange. The proposed method of prediction is at present limited to infants studied under basal conditions, but it is probably applicable to other than basal conditions so long as visible perspiration is not present and in the absence of derangement of the water metabolism. In the authors' clinic [Dept. of Pediatrics, Cornell University Medical College, N. Y.] this method is now being used for estimating the basal metabolism of infants, and it is recommended for clinical purposes.—*Authors' summary and conclusions.*

424. **MEYER, FRITZ.** Die spezifisch-dynamische Wirkung des Fleisches beim mit Schilddrüse behandelten Tier. (Zugleich ein Beitrag zur Theorie der spezifisch-dynamischen Wirkung.) *Biochem. Zeitschr.* 208(1/3): 127-150. 4 fig. 1929.—The specific dynamic action of a determined amount of meat before and after thyroidin administration was determined on dogs. After one thyroidin dose, which alone raised the metabolism 47%, the specific dynamic production of heat from 500 gms. of meat fell from 67 to 24 calories. After 70% effect from thyroidin the S.D.A. was only 10 cal. It is assumed that the transformation of the food material, of which the S.D.A. is an expression, gives way under thyroid action to direct combustion of the food fed. With this view, the findings of Pahon and Abelin, who report a diminution of glycogen especially in the liver, are in good agreement.—*F. Meyer (transl. by R. G. Turner).*

425. **MITCHELL, H. H.** The significance of surface area determination. *Jour. Nutrition* 2(5): 437-442. 1930.—The surface areas of chickens and rats are found to vary considerably with changes in the position of the body trunk and its appendages. The author believes that the heat produced per sq. m. of body surface possesses no absolute meaning but may still be highly useful for comparative purposes, especially between animals of the same species, if the measurement is made by exactly the same method in all cases.—*E. L. Batchelder.*

426. **MITCHELL, H. H.** The surface area of single comb white Leghorn chickens. *Jour. Nutrition* 2(5): 443-449. 1930.—A detailed description of the method used in determining surface area is given and the following prediction formula calculated from the data is presented: $S = 8.19\ W^{.705}$. This is a distinct improvement over the Meeh formula and was not improved by introducing a factor defining nutritive condition. Separate equations for males and females could not be derived from the present data but there are indications that sex is a determining factor.—*E. L. Batchelder.*

427. **MONTMOLLIN, CLAUDE DE.** Contribution à l'étude du métabolisme de base et de l'action dynamique spécifique des protéines. *Schweiz. Med. Wochenschr.* 59(36): 917-920; (38): 961-964. 1929.—Increased B.M.R. was found in hyperthyroidism, diabetes, hypophyseal cases; organo-vegetative cases, no definite conclusion; nephritis, mostly normal; lymphogranuloma, increase; cutaneous affections, normal. Specific dynamic action was normal in 16 cases of colloid goiter, 2 cases after thyroidectomy, 3 mild diabetics, 2 convalescent nephritics, 7 cutaneous affections; it was low in 7 toxic goiters, 1 thyroidectomy (toxic), 4 severe diabetics, 1 mild diabetic, 1 convalescent nephritic, 1 case of adiposity, 1 of acromegaly, 1 lymphogranuloma, 1 uremia, 1 lymphogranuloma treated by x-ray; it was increased in 1 colloid goiter under the influence of synthetic thyroxin, 2 thyroid ligations, 6 nephritic cases; it was without any regularity in 1 hypophyseal tumor case and 7 cases of organo-vegetative disturbances. In general, the specific dynamic action of proteins is increased in cases with low B.M.R. and lowered with high initial B.M.R.—*H. J. John.*

428. **OBRESHKOVE, VASIL.** Oxygen consumption in the developmental stages of a Cladoceran. *Physiol. Zool.* 3(2): 271-282. 1930.—This paper deals with the rate of O consumption of *Simocephalus exspinosus* in 5 stages of development. The rate of gaseous metabolism as determined by the rate of O consumption is compared with the 1st-instar young, size considered. If the rate of O consumption of the 1st-instar young, as determined by a modified Thunberg microrespirometer, be represented

by 100%, then for the 3rd-instar young the rate becomes 96.4%; for the 1st-brood mothers, 52.1%; for the 3rd-brood mothers, 50.8%; and for the 5th-brood mothers, 41.8%. In the 9th-brood mothers a further decrease in the gaseous metabolism of the individuals is indicated by their rate of CO_2 production, which was found to be 44.3% of that of the 5th-brood mothers, determined colorimetrically. It is concluded that senescence in this species is progressive and that it is primarily a decrease in the rate of dynamic processes of the individuals.—*Author (courtesy Wistar Bibl. Serv.).*

429. PERONI, ACHILLE. Ricerche sul metabolismo basale e sul valore energetico degli alimenti nelle regioni artiche. *Boll. Soc. Ital. Biol. Sperim.* 5(2): 225-226. 1930.—From 7 individuals whose basal metabolism was studied during a trip in the Arctic regions, in 6 a moderate decrease was observed. The value remained however in physiologic limits. When fat diet was consumed, an increase of basal metabolism was observed together with an increase of the respiratory quotient to 0.86: an explanation of this rise is wanting.—*M. Comel.*

430. PLASS, E. D., and WAYNE A. YOAKAM. Basal metabolism studies in normal pregnant women with normal and pathologic thyroid glands. *Amer. Jour. Obstet. & Gynecol.* 18(4): 556-568. 2 fig. 1929.—Basal metabolic rates were determined at short intervals upon 72 women during pregnancy and after delivery. In 48 women showing normal thyroid activity (a maximum rate of not more than plus 20%), the metabolic rate increased approximately 10%, on the average, in the latter half of gestation, probably due to the added increment of fetal metabolism. When the thyroid was abnormal, 24 cases, the basal rate rose to higher levels, the pregnancy aggravating hyperthyroid tendencies. In patients with goiters, the prophylactic administration of small doses of I generally prevented further enlargement and occasionally led to a reduction in size. Such I administration to the pregnant woman effectively prevented enlargement of the fetal thyroid even when the mother had a considerable goiter.—*E. D. Plass.*

431. POMMERENKE, W. T., H. F. HANEY, and W. J. MEEK. The energy metabolism of pregnant rabbits. *Amer. Jour. Physiol.* 93(1): 249-257. 1930.—During pregnancy in the rabbit there is a progressive increase in energy metabolism; on a basis of weight, from a normal of 2.61 calories per Kgm. per hr. to 3.19 in the last 5 days of the gestation period; and on a basis of surface area, from 32.73 to 41.50 calories per sq. m. per hr. The total metabolism is not markedly changed at birth; that is, the total heat production of the mother just before parturition is about equal to that of the mother and young combined just after parturition. If the fetus be considered as a separate organism and its surface area plus that of the mother be used in computing the metabolism, no increase in rate is evident during pregnancy. During the early post-partum period the metabolism of the rabbit, both per unit of weight and per unit of surface area, is considerably above normal.—*Authors' summary.*

432. REINWEIN, HELMUTH. Studien über den Mechanismus der spez.-dynamischen Eiweisswirkung. *Deutsches Arch. Klin. Med.* 160(5/6): 278-299. 1928.—The Warburg method was employed to investigate the specific dynamic increase in metabolism in very thin sections of tissue saturated with O. Ammonia, ammonium salts, and amines increase oxidation in surviving hepatic tissue more than do OH ions alone. Increase of O consumption occurs. Deamination seems to be the primary process. However, increased O consumption depends upon the amino acid residue. Histidin splits off much ammonia in the surviving tissue, causing no increase of oxidation, though increasing metabolism in dogs.—*B. Bickel.*

433. SCHADOW, HERMANN. Grundumsatz und spezifisch-dynamische Wirkung bei gesunden Säuglingen im Vergleich mit den Befunden bei Erwachsenen und älteren Kindern. *Jahrb. Kinderheilk.* 126(1/2): 50-74. 1929.—A simple metabolic apparatus is described in detail. Its limits of error are between 3 and 5%. Basal metabolism is somewhat higher than for adults or older children. It may be that part of this difference is due to the movement of very young children even when they are at rest. Specific-dynamic action of protein given as buttermilk was 13.7 and 15.7% on children fed artificial diet and only 8.5% with children on human milk.

434. SCHAFERSTEIN, S. J. Zur Charakteristik der Oxydationsprozesse bei Säuglingen. *Arch. Kinderheilk.* 89(3): 191-201. 1930.—The respiratory quotient of normal infants during the course of a day varies between 0.8 and 1.0. In acute disturbances of digestion and intoxications the respiratory quotient rose. There was often a clear parallelism between rise in the O/N quotient and development of clinical symptoms. The quotient returns to normal faster than the symptoms abate. Acute disease increased the quotient. Compensated forms of glandular tuberculosis had the same values for the O/N quotient.

435. SCHENK, PAUL, und KARL CRAEMER. Der Einfluss schwerer körperlicher Arbeit auf den menschlichen Stoffwechsel. *Arbeitsphysiologie* 2(2): 163-186. 1929.—The blood and urine of contestants of the Amsterdam Olympic were investigated with respect to several organic and inorganic constituents. The largest lactic acid excretion in the urine was by a sprinter (400 m. in 47 3/5 sec.) and was higher even than after a Marathon race of 2 hours and 50 min. With weight lifting the excretion was slight and the level in the blood little affected. Considerably larger accumulation was found in the blood and urine of wrestlers and boxers. The phosphoric acid in the urine rose after 10 min. boxing from 0.1 to 0.27 mgms %. The sulphuric acid content was greatest after a Marathon run and after 5 hrs. street bicycling contest. The C: N quotient rose during a Marathon run from 1.25 to 1.905. The fat content of urines before contest was about 1 mgm. per 100 c.c. and rose after the contests 20 to 25 mgm. per 100 c.c. of urine.—*T. M. Carpenter.*

Med.* 71 (1/2): 298-302. 1 fig. 1930.—Criticism of the Knipping apparatus and suggestion of an improvement.

437. SCHLUMM, F., und H. J. BRECHMANN. Über die spezifisch-dynamische Wirkung der Leber. *Deutsches Arch. Klin. Med.* 166(5/6): 362-369. 1930.—The specific-dynamic effect of meat and liver (and in some cases, of other organs, such as thymus) was studied in 45 series of experiments on 15 metabolically normal persons. Meat gave values corresponding fairly well with those found by earlier investigators, calves' liver gave values 40% to 50% lower. Ox liver in only 2 cases gave a higher value than did meat (muscle) with like N values. Liver preparations gave values consistently corresponding to the N content. Thymus gave no consistent results. —*From authors' summary (transl.).*

438. SZARKA, A. Der Einfluss des Ovarialzyklus auf den Grundstoffwechsel der Ratte. *Pflüger's Arch. Ges. Physiol.* 222(5/6): 690-698. 1 fig. 1929.—The basal metabolism of rats during the proestrus and estrus was about 25% of that in the meta- and diestrus. There is a rhythm in metabolism which parallels changes in the ovary. The highest value obtained for ♀ rats was equal to the average ♂ value, which was 798.5 Cal. per 24 hr. and sq. m. of body surface.

439. TOPPER, ANNE, and HANNAH MULIER. Basal metabolism of children of abnormal body weight. I. Basal metabolism of overweight children. *Jour. Amer. Med. Assoc.* 92(23): 1903-1907. 1929.—The basal metabolism of overweight but otherwise normal children is usually normal, with a tendency to be high. There is an increased basal metabolic rate in a certain percentage of overweight children which may be partly accounted for on a basis of continued overfeeding. There may be some association between the prepuberty period and an increased basal metabolic rate. The increase in growth,

increased activity of the endocrine glands and awakening of sexual life, all may influence the basal metabolism of the child. There may be a temporary dysfunction of the thyroid gland at this period manifested by no other sign than an increased basal metabolic rate. If there is an association between prepuberty and an increased basal metabolic rate, the fact that this period occurs somewhat earlier in girls than in boys might account for the greater proportion of girls in this series who showed a marked increase in basal metabolism at this age period. Further studies in individual cases during this important age period are necessary.—*Authors' conclusions.*

440. WANG, CHI CHE, and JEAN E. HAWKS. Recent advancement in the study of basal metabolism in health and disease. *Jour. Amer. Dietetic Assoc.* 5(3): 184-197. 1929.—A review.

441. WANG, CHI CHE, JEAN E. HAWKS, BERNICE HUDDLESTUN, AGNES A. WOOD, and EDITH A. SMITH. The influence of high and low protein diet on the basal metabolism and the chemistry of blood and urine in normal women. *Jour. Nutrition* 3(1): 79-98. 1930.—Six normal women (17-36 years old) received for 5 weeks a diet of 2 gms. protein per Kgm. and sufficient carbohydrate and fat to make 40 calories per Kgm. body weight. The protein was then decreased until a level of 0.6 gm. per kgm. was reached at a constant caloric value of 40. This diet was maintained 4 wks. After a month's interval, a 2 wks. period was carried out on a freely chosen normal diet. No marked difference in the basal metabolic rate was observed during the 3 periods. Non-protein N, urea, and creatine of the blood increased in the high protein period. Uric acid, creatinine, and Ca did not change. Sugar increased slightly and blood lactic acid markedly in the low protein period. Creatinine remained constant throughout while total urinary N, urea, NH_3, uric acid, and creatine varied directly with the protein intake. Total urinary acidity varied with the protein intake while urinary lactic acid remained constant. No difference was found in blood pressure.—*E. L. Batchelder.*

Physiol.* 3(3): 315-324. 1929.—The basal metabolism of 95 vegetarian and 96 omnivorous rats between the age of 5 and 9 mos. have been determined. The basal metabolism of the vegetarian rats is slightly lower than that of the omnivorous rats.—*Authors' summary.*

WATER BALANCE

445. ADLERSBERG, D., und A. PERUTZ. Experimentelle Untersuchungen über den Wasserhaushalt der Haut mittelst der Quaddelprobe. 1. Resorptionsbedingungen der intrakutanen Kochsalzquaddel. *Arch. Exp. Path. u. Pharmakol.* 151(1/2): 101-105. 1930.—In rabbits the absorption of intradermal NaCl deposits depends on age and the condition of the skin. Also, the region of the injections had some effect, e.g., a drop placed in the skin of the forehead was more quickly absorbed than when placed in the back of the same animal. Before beginning experiments the animal and its body regions should be standardized. Food rich in salt accelerates absorption.—*H. Graf.*

446. BAAR, HEINRICH, und HANS BENEDICT. Über die Quaddelzeit im Kindesalter und ihre Beziehungen zum Wasserhaushalte. *Zeitschr. Kinderheilk.* 49(5): 551-571. 2 fig. 1930.—Study of the disappearance time (QuZ) in 72 healthy children and about 200 with various diseases shows that: The QuZ in the new-born is very short and subject to great individual variation; a rise, first rapid, then slow, follows the 2nd month of life. A shortened QuZ occurred, almost always in manifest and latent tetany, in severe cases of icterus, in 1 case of marked obesity, and in the pasty type of exudative diathesis (but normal QuZ in thin subjects with exudative diathesis). No regular changes in QuZ were observed in febrile diseases. Scarlatina showed a very marked shortening, serum and nirvanol exanthemata a distinct shortening, and measles a moderate shortening, of the QuZ. Oral administration of $NaHCO_3$ and NaCl produced a shortening, orally given NH_4Cl and Ca a lengthening, of the QuZ. Warm applications, but not mustard erythema, shortened the QuZ. The QuZ seems to be determined in the first place by the capacity of the connective tissue substance for swelling; the actual water content seems to be of decisive importance only in cases of high-grade edema in which the elevation disappears almost immediately.

447. BOSCH, OSKAR. Über Ursache und Verlauf kurzfristiger und tagesperiodischer Schwankungen im Wasserhaushalt des Säuglings. *Zeitschr. Kinderheilk.* 49(4): 361-374. 5 fig. 1930.—Several series of observations were made on 64 infants in the Berlin orphan asylum. The questions studied were whether the daily rhythm of excretion is caused by times of administering food, muscular movements, etc., or is a true endogenous periodicity, independent of external stimuli; and, if the latter, what factors are responsible for the usual rhythm of greatest urinary output in the afternoon, decrease in the night and increased flow in the morning. Experiments in feeding showed that each meal stimulates secretion, but that the degree of stimulation varies according to the phase of the daily rhythm in which the effects are felt: an additional meal is more stimulating to urinary secretion if the stimulus becomes effective within the regular daily period of high secretion; omission of a meal reduces secretion more if the inhibition becomes effective within the regular daily period of reduced excretion. Change in the hours of sleeping and waking had no material effect on the urinary rhythm. Increased bodily exercise produced an increase in total urine output, but no change in the daily rhythm. Comparison of highly concentrated and watery diets in their effects on urinary output showed that a relatively low metabolic activity favors water excretion, while heightened metabolism makes greater demands on the water economy and lowers excretion. All these external influences, while they have an effect on the water economy, are insufficient to explain the daily rhythm.

448. JANKOWSKY, W. Die Bedeutung des Pankreas für den Wasserhaushalt. *Fortschr. Med.* 44(11): 540-542. 1926.—The insular portion of the pancreas influences water retention whereas the non-insular part favors water excretion. The lessened insulogenic function in diabetes causes increase in water output which results at first in an increased water intake, later an emaciation if the water balance is negative for a longer time. The over-function of the insular portion through over-dosage of exogenous insulin leads to lowering of urine output and finally to edema. The author states that the increase of water output is not secondary to sugar excretion but depends on the lessened insulogenic function. The pancreas, therefore, even in the normal, is closely bound up with the intermediary water metabolism. In a depancreatized animal (experimental diabetes), we have lessened water output, because here not only the insulogenic but also the rest of the gland which stimulates excretion is removed. Insulin injection reduces

water output and causes also water retention up to the point of edema.—*H. J. John.*

449. ROSE, WILLIAM B., CHARLES J. STUCKY, LAFAYETTE B. MENDEL, and GEORGE R. COWGILL. The relation between anorexia, anhydremia and gastric atony in dogs deprived of water. *Amer. Jour. Physiol.* 96(1): 132-138. 1931.—Dogs in good nutritive state were fed an artificial ration complete in every known respect. Their appetite for this diet was excellent; repeated gastric tracings showed vigorous hunger contractions, good tonus variations and rhythm. Blood analyses revealed normal values for sugar, hemoglobin, total solids and chlorides. The animals were then deprived of water and the relationships between appetite, anhydremia and gastric motility studied. Five experiments were performed with 4 dogs. A moderate increase in blood concentration, an increase in hemoglobin value of less than 20%, was associated with a definite decrease in the motor activity of the empty stomach and partial or complete loss of appetite. A greater increase in blood concentration resulted in gastric atony in every case. In 1 instance, when characteristic hunger contractions were absent but some tonus changes persisted, the animal ate all food offered; in the other cases, however, where atony of the stomach was recorded, there was a complete loss of appetite. Since anhydremia is a systemic disturbance it is suggested that other organs, particularly muscles, may fail to function with optimum efficiency in the presence of a moderate degree of anhydremia.

450. WÖHLBIER, WERNER. Die Bedeutung des Wassers für das Wachstum der Tiere. *Tierernährung* 2(6): 530-542. 1931.—The animal begins its development after fertilization of the egg with a considerable relative increment of water, possibly amounting to 97%. This quantity is chiefly bound colloidally to protein, which may aid intensive cell-division. Now the percentage increment of substance is higher than is reached again during the whole life; for soon the rate of growth decreases; this may be caused by a diminishing ability of the protein to swell. Gradually growth becomes more and more insignificant, finally coming to a stop when the protein contains about 77% of water, the usual content of the adult animal. The high rate of fixation of water in the growing animal, in connection with the high total metabolism, requires nutriment very abundant in water for the young animal. On the other hand, an influence is exercised upon the formation of the organs by the high rates of their water metabolism.—*Author's summary.*

PROTEIN METABOLISM

451. [BACH, A., and D. MIKHLIN.] БАХ, А., и Д. МИХЛИН. Ферментативное превращение ксантина и гипоксантина в мочевую кислоту без участия посторонних акцепторов водорода. [Enzymic transformation of xanthine and hypoxanthine into uric acid without the cooperation of foreign H-acceptors.] [German summary.] *Jour. Biol. et Méd. Exp.* [*Moscow*] 7(18): 385-392. 1927.—Using the milk enzyme purified by Sbarsky and Michlin (identical with the Schardinger enzyme), the authors succeeded in transforming xanthine and hypoxanthine into uric acid without the cooperation of a foreign hydrogen acceptor. The presence of free O is thus entirely unnecessary, since the reaction can be carried out under strictly anaerobic conditions. The nature and the nomenclature of the oxidizing-reducing enzyme is discussed.—*Authors' summary (transl.).*

452. BERGMANN, MAX. Zur Kenntnis der Eiweissbausteine und ihrer enzymatischen Umwandlungen. *Naturwissenschaften* 18(20/21): 465-468. 1930.—Acyl amino acids are easily racemized under the catalytic influence of acetic anhydride. This is explained by the enolization of the α carbon atom. By means of substitution (acylating, chloracetylating) and other structural changes (converting the open chain amino acids into 5-atom hydantoin or azlactone rings) the amino acids are catalyzed for dehydration, that is for conversion into amino-acryl acids and subsequently into α ketoacids, for which process it has been possible to determine the intermediate steps. Conversely, the amino acids may again be built up from α ketoacids and ammonia derivatives followed by hydration. As hydrogen donators saturated amino acids may function by giving up their hydrogen to the unsaturated. The described model experiments give a picture of fundamental mechanism of the activating processes which enzymes effect in their substrate in protein synthesis and hydrolysis.—*M. Bergmann (transl. by W. E. Thrun).*

453. BONATI, G. Il comportamento del glutatione nei cani prima e dopo la tonsillectomia. [Behavior of glutathione in dogs before and after tonsillectomy.] *Ateneo Parmense* 2(5): 435-444. 1930.—The glutathione content of the tonsils (69-112 mgm. per 100 gm. tissue) and of the blood before and after tonsillectomy was determined for 7 dogs. After tonsillectomy there was a diminution of the blood glutathione by about 1/5, lasting 3-5 days; then an increase above normal, lasting 10-15 days; finally a return to stability at the preoperative level. Bonati attributes the various perturbations in glutathione content to the operative hemorrhage. The results, he believes, deny to the tonsil any important function in glutathione metabolism.

454. BORNSTEIN, A., und R. PANKTE. Cyansäure als Zwischenprodukt des Aminosäurestoffwechsels. *Biochem. Zeitschr.* 225(4/6): 330-335. 1930.—In 10 experiments dogs injected continuously with intravenous doses of Na cyanide showed slightly toxic symptoms. The ammonia content of the blood remained unchanged. After similar injections of amino acids (glycocoll, alanin, asparagine) there occurred a greater rise in the blood ammonia, which proves that the above mentioned amino acids form no cyanic acid as intermediate products in their deamination. After very great doses of cyanide there occurs, as a result of violent convulsions, ammonia formation in the blood.—*Authors' conclusions (transl. by O. D. Abbott).*

455. BÜTTNER, H. E. Untersuchungen über den Schwefelstoffwechsel. *Zeitschr. Ges. Exp. Med.* 72(3/4): 337-364. 1930.—This study is an inquiry into the soundness of the commonly accepted principles of S metabolism, namely: 1. There is an endogenous and an exogenous S metabolism. The amount of the inorganic sulphate excreted is determined chiefly by protein intake. 2. Neutral S is independent of diet, for it is somewhat diminished on a high-protein regimen; hence it appears to originate from endogenous metabolism. 3. The esters of sulphuric acid are formed largely by the intestinal putrefaction of aromatic protein bodies. Experiments with egg and asparagus diet on 37 healthy persons (54 experimental days) showed that neutral S may be produced by increased protein in the diet. Hence, though neutral S is mainly endogenous, it may be influenced by food. The excretion of neutral S was found high in 29 diabetics (65 experimental days) as compared with the normal; but while in normal persons on increase of cystin in the diet the sulphate S: neutral S ratio remained about the same, in diabetics there was a relative and often an absolute decrease after increased cystin administration. Phlorhizin administration in 4 rats produced increased neutral S excretion. Cyanide intoxication in 2 rabbits increased the total S excretion, which continued after the day of poisoning, even though the animal ate less, and which must therefore be endogenous. The sulphate S as well as the neutral S was increased, showing that sulphate S may likewise be formed in endogenous metabolism. While endogenous and exogenous S metabolism are in the main distinct, these experiments show that in many cases what affects the one affects also the other. This implies considerable modification of the principles outlined above.

456. CHOLOPOFF, A. D. Herkunft und Verteilung des Blutammoniaks nach Untersuchungen an angiostomierten Hunden. *Pflüger's Arch. Ges. Physiol.* 218 (5/6): 670-676. 1928.—There are 3 places of ammonia

formation: the chief place is the cecum and appendix, where ammonia is produced by micro-organisms, the 2nd place of importance is the kidney and the 3rd the intestine during digestion. The liver retains ammonia that has been excreted into the portal vein, but the liver itself produces no export ammonia.

457. **DAMAS, L. Revue de chimie biologique. Le glutathion.** *Bull. Sci. Pharmacol.* 37(8/9): 501-507. 1930.—Review of the chemistry and physiology of glutathione, with bibliography.

458. **EDLBACHER, S. Die Strukturchemie der Aminosäuren und Eiweisskörper.** 188p. Franz Deuticke: Leipzig, 1927. Pr. 12 M.—This book is a brief compilation of information up to the date of publication, concerning the chemistry of amino acids and proteins. Because of rather limited size an exhaustive presentation is not attempted, discussion of physical characteristics and constants being largely omitted. The author emphasizes, rather, questions bearing on the determination of structure from the point of view of organic chemistry. The subject matter is divided into 3 sections treating respectively the free amino acids, anhydrides and polypeptids and, lastly, natural proteins. It furnishes a very satisfactory outline of the organic chemistry of these bodies.—*J. C. Andrews.*

459. **EDLBACHER, S., und J. KRAUS. (Mitwirkung von N. SCHEURICH.) Zur Kenntnis des intermediären Stoffwechsels des Histidins. II.** *Hoppe-Seyler's Zeitschr. Physiol. Chem.* 191(5/6): 225-242. 1 fig. 1930.—As yet histidinase has been found only in extracts of the liver. It is not the same as arginase. Histidine is broken down to 2 molecules of ammonia, one of glutamic acid and probably one of formic acid. The reaction proceeds by way of intermediates as yet unknown, possibly through pyrollidon carboxylic acid as a precursor of glutamic acid. The enzyme has decided specificity, attacking only the naturally occurring optical isomer, but not imidazole, imidazole-lactic acid, imidazole-ethylamine, methylhistidine, and probably not carnosine and the methyl ester of histidine. Since no reaction occurs on the optically active carbon atom, it seems evident that the naturally occurring l-histidine and d-glutamic acid belong to the same stereochemical group.—*R. C. Corley.*

460. **FRISCO, ANGELO di. Sur le métabolisme de l'azote. V. Sur l'élimination éventuelle de NH_3 par voie cutanée et pulmonaire chez les rats à jeun recevant des sels ammoniacaux. VI. Déterminations comparatives par les méthodes de Kjeldahl et de Dumas de l'azote total des tissus et des liquides organiques dans différentes conditions expérimentales.** *Arch. Internat. Physiol.* 33(1): 98-102; (2): 137-141. 1930.—V. Rats were placed each within an apparatus so constructed that urine and feces dropped through a wire net for collection, while the expired air was withdrawn across a titrated solution of H_2SO_4 for analysis; 2 rats were fed NH_4 salts, while 4 rats were starved to death. All showed considerable, though varying, N deficits in the organism at death, deficits not accounted for by the fecal and urinary N excretion. At the same time the amounts of NH_3 found in the expired air (to which urinary decomposition may have contributed) was insignificant. These results fail to sustain Tigerstedt's suggestion that the deficit of N in the urine and feces of animals fed NH_4 salts may be explained by pulmonary elimination of NH_3. VI. This study was undertaken to determine whether the N deficit unaccounted for by urine and feces might be merely N which cannot be determined by the Kjeldahl method. The Dumas method gave higher values than the Kjeldahl—2.78% and 10.1% more for the tissue pap of 2 rats dead of starvation, 8.62% and 12.5% higher for that of 2 rats with ligated bladder, 8.82% for that of a normal rat. The urines of 3 rats dead of starvation gave respectively 7.3%, 6.23% and 5.63% more N by the Dumas than by the Kjeldahl method. The differences between the 2 methods used on tissue pap, then, were practically the same in the rats dead of starvation as in those dying of ligated bladder, while the difference between the methods as used on urines was not sufficient to explain N deficit of 35-50%. The N deficit, therefore, cannot be explained by inadequacy of the Kjeldahl method.

461. **HOPKINS, F. GOWLAND. Denaturation of proteins by urea and related substances.** *Nature [London]* 126(3175): 383-384. 1930.

462. **KAUFFMANN, FR., und E. MISLOWITZER. Über den fermentativen Abbau des Histidins.** *Biochem. Zeitschr.* 226(4/6): 325-337. 1930.—The cleavage of ammonia from histidine by means of pulp and glycerin extracts of liver of guinea pigs, rabbits, dogs and cats was investigated. In 40 experiments the ammonia formation was explained by the action of a desamidase. In 3 experiments the ammonia N value was plainly higher than the 33.3%, namely 37.2, 38.3 and 38.7%. This excess is however so small that this anomaly can give no information as to the action of specific ferments. We are therefore not in a position, from our work, to decide as to the presence of the histidase of Edlbacher.—*Authors' summary (transl. by E. G. Schmidt).*

463. **KISCH, BRUNO. Harnstoffuntersuchungen bei Selachiern.** *Biochem. Zeitschr.* 225(1/3): 197-207. 1930.—The urea was determined in various species and a number of specimens of selachians, including 12 of *Torpedo ocellata* (6 ♂ and 6 ♀), 5 of *T. marmorata* (3 ♂, 2 ♀), 6 of *Scyllium canicula* (2 ♂, 4♀), 2 of *S. stellare* (1 ♂, 1 ♀), 6 of *Mustelus laevis* (4 ♂, 2 ♀), 2 of *Raja asterias* (1 ♂, 1 ♀), 2 species of *Trygon*, 1 specimen of each, 2 specimens of *Squatina angelus* and 1 of *Sphyrna zygaena*. Studies were made of blood, urine, cerebrospinal fluid, perilymph and endolymph from the organ of hearing, ventricular fluid, pericardial and perivisceral fluids, bile, cardiac muscle, body muscle, electric organ and spleen, under the influence of hunger, loss of blood, suffocation, removal of the liver and removal of the interrenal organ.

464. **KOPLOWITZ, E. Wechselbeziehungen zwischen Kreatin- und Kohlehydratstoffwechsel. IV. Einfluss subcutaner Insulininjektionen auf den Kreatinin- und Kreatinspiegel des Blutes.** *Zeitschr. Klin. Med.* 113 (5/6): 605-610. 3 fig. 1930.—In addition to the fall in blood sugar a decrease in the creatine level of venous whole blood occurs after subcutaneous injection of 40 units of insulin into diabetics. In most cases the subsequent rise in the bloodsugar curve was accompanied by a parallel increase in the creatine. Changes in the creatine level of the same type and magnitude occurred in normal subjects only when evident hypoglycemic symptoms were present. The observed variations in plasma creatine lie within the limits of experimental error. The same is true of creatinine in plasma and whole blood.—*E. Koplowitz (transl. by H. Zwarenstein).*

465. **KOTSCHNEFF, NINA. Weitere Untersuchungen über das Verhalten verschiedener Eiweissabbauprodukte im Intermediärgebiet nach Versuchen an angiostomierten Hunden.** *Pflüger's Arch. Ges. Physiol.* 218(5/6): 635-641. 1928.—The intestinal wall allows not only simple amino acids but also very complex amino acid compounds to pass through. In starvation the passage of amino acid N and polypeptid N from the blood into various organs and to the blood from organs can be accurately determined. Polypeptid N in fasting dogs comes chiefly from the spleen. During the period of digestion polypeptids are synthesized not only in the liver (.62 mgm. %), spleen (.5 mgm. %), intestine (.42 mgm. %), and muscle (.14 mgm. %), but also in the kidney.

466. **LOMBROSO, UGO, et SALVATOR di FRISCO. Sur le métabolisme de l'azote. IV. Sur le contenu total en azote de l'organisme des rats à écoulement urinaire empêché. III. Influence de la constitution chimique des protéines sur l'élimination de l'azote en forme non justifiée.** *Arch. Internat. Physiol.* 33(1): 92-97; (2): 109-136. 1930.—IV. In 22 rats urinary flow was blocked by ligature of the bladder or of the renal vessels or by nephrectomy; 16 survived 44-73 hrs. and 6 survived 96-240 hrs. The latter group presented diarrhea and incessant vomiting, which eliminated a large amount of N, thus resembling rats dead of hunger except that the N was elimi-

nated in smaller quantities. In the rats dead with the greatest loss of weight (up to 30%) and after a long survival, the percentage of N was higher than in those dying earlier and with less loss in weight, but never so high as in animals dead of starvation, and only slightly higher than in normal animals. The results indicate: (1) that it is not possible to modify greatly the N constant in albino rats; (2) that after arrest of urinary excretion the animals do not tend to accumulate all the N metabolized. This suggests that an important fraction of the total N may escape from the organism under some as yet undefined form. III. The fact that as much as 50% of the N of the NH_3 salts administered to rats may fail to appear in the urine and feces recalls the further fact that in fasting rats the urine and feces fail to account for all the N from the protein destroyed in the wasting tissues, this deficit also being sometimes as high as 50%. This raised the question whether the escape of N from the organism by unknown channels is dependent on the form of protein in which it occurs. Experiments on 12 rats showed that the N fed in casein, egg albumin, gelatin and meat was in various degree incompletely accounted for in the excreta. The authors conclude that the study of N metabolism cannot ignore the factor of possible elimination of large amounts of N under a form and by a route as yet not defined.

467. **LUCKE, HANS. Beiträge zur Physiologie und Pathologie des menschlichen Harnsäurestoffwechsels. VI. Mitteilung. Der Harnsäuregehalt der Galle in der Norm und bei Erkrankungen der Gallenwege.** *Zeitschr. Ges. Exp. Med.* 72(5/6): 753-759. 1930.—Colorimetrically determined according to the principle of Folin and Wu, uric acid was found in normal duodenal (number of cases not stated) bile in concentrations of about 2 mgm., but in values inferior to those of the blood. The bile of the gall-bladder is richer in uric acid, but, since it is a thickened secretion, these values cannot be averaged. In severe inflammatory diseases of the bile-ducts the uric acid content of the duodenal bile sometimes was observed to exceed the blood values, since an enterogenous is therein added to an enterotropic value.

468. **LYON, EDOUARD E. The effect of diet on the blood chemistry and the longevity of the double nephrectomized dog.** In: Northwestern Univ. Med. School Dedication Ward Memorial—Alexander McKinlock Memorial Campus, Chicago, June 15, 16, 17, 1927. 169-174pp. The Lakeside Press, R. R. Donnelley and Sons Co.: Chicago, 1927. $1.00.—Removal of both kidneys resulted in the development of a condition simulating that seen in patients with latent or asthenic uremia. There was a gradual loss of strength with anorexia, vomiting, diarrhea, and occasionally salivation, increasing stupor, coma and finally death. Edema and convulsions were not observed. The average length of life following the removal of both kidneys from dogs on a meat diet was 105.6 hrs. and from dogs on a bread, milk and lactose diet was 147.5 hrs. The latter diet, therefore, prolongs life after double nephrectomy. In the animals kept on this diet it was found that following removal of both kidneys the urea N and non-protein N content of the blood did not rise so rapidly.—*Author's summary.*

469. **MENDEL, LAFAYETTE B. [With T. B. OSBORNE.] The nutritive value of the wheat kernel and its milling products.** *Leopoldina* 4: 72-115. 1929.—The quantity of protein furnished by the entire wheat kernel which is necessary for continued maintenance of adult rats is greater than that required when proteins of milk or of various other food products are fed. For normal growth of the young this difference is much more pronounced. The "crude protein" of the commercial embryo is superior to that of the entire kernel or of the endosperm in maintaining adults. For satisfying the needs of growing rats the embryo proteins are somewhat more efficient than are those of the entire kernel and much more efficient than are those of the endosperm. The "crude protein" of commercial bran if eaten in sufficient quantity is somewhat superior to that of commercial embryo and decidedly superior to that of the endosperm in promoting the growth of young rats. For maintaining adults the proteins of the endosperm are adequate; they are inadequate for growth. Additions of meat, milk, or eggs to wheat flour so greatly enhance the value of the protein for growth that a great economy in consumption of protein results. Under the ordinary human dietary conditions the proteins of wheat are advantageously employed. Commercial wheat embryo is rich in the water-soluble vitamin. Commercial bran and flour contain much less of this important food factor. The pure embryo carefully separated from all the other parts of the seed and used as the sole source of vitamin suffices to maintain young rats, but fails to promote their growth, even when supplied in quantities equal to the amount of pure embryo contained in such quantities of the commercial embryo as were sufficient to promote full normal growth. Wheat kernels from which the embryo has been carefully removed are still rich in water-soluble vitamin. Rats fed for 1 year from the time of weaning on diets containing 92% of wheat or 50% of commercial wheat embryo reached full maturity without giving any evidence that wheat contains a toxic substance. The relation of these experiments to the problems raised by modern milling methods and the degree to which it is desirable to mill flour for general use have been discussed.—*Author's summary.*

470. **MOCHNATSCH, W. O. Bildungsstätte und Schicksal des Kreatins und Kreatinins nach der Angiostomiemethode.** *Pflüger's Arch. Ges. Physiol.* 218(5/6): 655-660. 1928.—During a fast period creatin is synthesized in the stomach, liver and kidneys, but during digestion it is formed only in the liver. The creatin formed passes into the general circulation and is taken out of the blood by various organs. The intestinal wall retains large quantities of creatin. Creatinin is produced from creatin.

471. **NEGRI, FERDINANDO. Nuovi contributi allo studio del problema delle vitamine. Le costanti chimico-fisiche del siero e del plasma sanguigno, il tasso glicemico, l'azoto, il carbonio, la creatina e la creatinina del siero di sangue e delle urine negli animali alimentati esclusivamente con carne autoclavata, od integrata con lievito di birra. [Physico-chemical constants of blood serum and plasma, the glucose, N, C, creatin and creatinine contents of blood serum and urine in animals fed exclusively on autoclaved meat or with addition of beer yeast.]** *Biochim. e Terapia Sperim.* 17(11): 445-460. 10 fig. 1930.—If dogs are fed an exclusive diet of autoclaved meat their survival does not exceed 2 mos. Rectal temperature decreases, and a remarkable hypothermy follows in the last week of life. An acidosis is produced, with decrease of pH of serum and alkali reserve. The refractive index of serum shows a constant and progressive diminution. A diminution of the C content of blood is accompanied by an increase of C in urine. The blood glucose content after an initial increase shows a rapid and remarkable diminution. The creatine and creatinine contents of urine are considerably increased. When to the meat diet beer yeast was added, a dog showed indefinite survival in good condition of health and body temperature. No acidosis followed, while the refractive index, C, and creatine contents of serum showed, after an initial stage, normal values. Hyperglycemia was observed. The creatinine content of urine was increased, but not so much as in dogs treated with meat alone. An abnormal production of organic acids is thought to develop in autoclaved meat, with acidosis following its administration. The yeast is thought to modify cellular oxidations.—*M. Comel.*

472. **NISHIMURA, KIKUGORO. Halogen benzene in animal bodies.** *Acta Scholae Med. Univ. Imp. Kioto* 12 (1): 73-78. 1929.—The influence of halogen benzene and cystine on the sulphur metabolism of rabbits was studied. Bromobenzene, chlorobenzene and iodobenzene were administered orally to different groups of rabbits (both fed and fasted), in dosages of 5 gm. daily for 5 successive days. The total urinary excretion of bromo-, chloro- and iodophenylmercapturic acid was subsequently determined quantitatively. The authors confirm other investigators who have shown that bromobenzene, chlorobenzene and

iodobenzene are excreted in the urine as p-bromophenyl-, p-chlorophenyl-, and p-iodophenylmercapturic acids respectively. The urinary excretion of mercapturic acid was significantly greater after the simultaneous administration of cystine and the halogen benzenes than after similar dosages of the benzenes alone.—*O. W. Barlow.*

473. PAPPALARDO, G. Sulla composizione chimica della caseina autoclavata in ambiente alcaline. [Chemical constitution of casein kept in autoclave in alkaline medium.] *Bol. Soc. Biol. Sperim.* 5(2): 29-32. 1930.—When casein is kept at 120° C. in alkaline medium changes are produced in its chemical constitution. One of the most remarkable is that the phosphoric acid, organically bound in the casein, is separated therefrom and changed to inorganic phosphoric acid. 20% of arginin and 30% of cystin are transformed into lower products. A fraction of NH_3 is set free, and the total N is therefore diminished.—*M. Comel.*

474. PARNAS, J. K. Über die Ammoniakbildung im Muskel und ihren Zusammenhang mit Funktion und Zustandsänderung. VI. Der Zusammenhang der Ammoniakbildung mit der Umwandlung des Adeninnucleotids zu Inosinsäure. *Biochem. Zeitschr.* 206(1/3): 16-38. 1929.—The author describes methods for the determination of amino purin and oxypurin as well as amino purin nucleotide and oxypurin nucleotide in small amounts of muscle tissue. By these methods he determined the amount of the nucleotides of adenine and hypoxanthine as well as adenine and hypoxanthine itself in frog muscle. In fresh muscle, in which traumatic ammonia formation was prevented, the purin bases were found for the most part as free nucleotide. Only about 4% of the amino purin N was present as pure nucleinic acid, free amino purin bases and nucleosides being practically absent because practically all the amino purin N was present as guanine nucleinic acid. Of the purin N present in fresh muscle of winter frogs 82% had adenine nuclei, 18% hypoxanthine nuclei. In summer frogs the corresponding values were 89 and 11%. The guanine nuclei represented only about 1.4% of the purin N. When the muscle was destroyed by mechanical means, a procedure which led to traumatic ammonia formation, the greater part of the adenine nucleotides were changed into inosinic acid. Within a few minutes after the muscle was triturated, the muscle brei contained only 23% of purin N in the form of adenine nuclei as against 77% as hypoxanthine nuclei of the nucleotides. In winter the deaminization of the adenine nucleotide is equivalent to the traumatic ammonia formation. In summer it is not possible to prove that this process is the only source of the ammonia formation. When frogs' muscle is fatigued under anaerobic conditions through stimulation of nerves the change of adenine into hypoxanthine is equivalent to the ammonia formation and appears to be the one source of this substance. When frogs' muscle works without fatigue, having an adequate supply of O, the conversion of adenine to hypoxanthine lags behind the amount of ammonia formed.—*B. Kramer.*

475. PARSONS, HELEN T. Urea concentrations in the blood of the rat in relation to pregnancy and lactation on diets containing varying concentrations of protein. *Jour. Biol. Chem.* 88(1): 311-330. 1930.—Striking fluctuations were observed in the urea concentration in the blood of rats subjected to varying conditions in respect to reduction of kidney tissue, concentration of dietary protein, and the burdens of reproduction. The highest concentration of urea, 191 mgm. per 100 cc. of blood, occurred in a lactating rat with one kidney, on a high casein ration. The increased food intake of the lactating females accounts only in part for the extreme values observed. A definite influence of the act of suckling itself on the concentration of urea during fasting has been demonstrated in the blood of intact rats as well as those with only one kidney, when the ration consumed previous to the fast was rich in casein, liver, or egg albumin, or contained only moderate amounts of protein. Inasmuch as the increases in the concentration of urea in the blood of the lactating rat following the suckling of the young seem not to be closely correlated with the amount of milk, it is possible that they result from an emotional response to the act of suckling itself rather than from the formation of milk in the mammary gland. An occasional slight increase in the urea concentration occurred following the taking of the blood sample without nursing, and may be related to the effect on blood urea shown by others to result from manipulation of the experimental animal. However, the increases in urea in the blood of rats following nursing were demonstrated to be of unmistakably greater magnitude than those resulting from the blood sampling itself.—*Author's summary.*

476. PASQUALINO, GUGLIELMO. Sur le métabolisme de l'azote. VII. Influence comparée des hydrates de carbone et des graisses sur l'utilisation de l'azote. *Arch. Internat. Physiol.* 33(2): 185-195. 1930.—Administration of different proteins (egg albumin, casein, gelatin) with either carbohydrates or fats to albino rats in 12 experiments resulted in no appreciable difference either in the utilization of the proteins or in the weight of the animal, except that once carbohydrate exercised a favorable influence on the utilization of gelatin; but it was impossible to obtain this result a 2nd time. In the case of gelatin also the use of carbohydrates produced a closer correlation between N administered and N excreted; this was not so in the case of the other proteins. The experiments as a whole showed neither a favorable action from carbohydrates on N metabolism (as the majority of authors maintain for different animals) nor a particularly favorable action from fats in the case of albino rats (as Maignon asserts).

477. PLATTNER, F., und H. HINTNER. Die Spaltung von Acetylcholin durch Organextrakte und Körperflüssigkeiten. *Pflüger's Arch. Ges. Physiol.* 225(1): 19-25. 1930.—In view of the importance of acetylcholin to the vegetative mechanism of the whole, and of the fact that it is rather rapidly hydrolyzed in the animal organism, the effect of various organic extracts on the stability of acetylcholin was studied. Extracts of liver, pancreas, brain, suprarenals, musculature of the small intestine, spleen, uterus, salivary glands, blood-vessels, thymus, iris, lungs, cardiac muscle, skeletal muscle, thyroid, peripheral nerve and kidneys saponified acetylcholin; so did cerebrospinal fluid, bile and aqueous humor. Saliva, cow's milk and human urine were inactive. The saponification is a fermentative process, which can be intensified by long-continued heating to 56°. The action of liver, pancreas, salivary gland, cardiac muscle, muscle of the small intestine, and thyroid was completely or strongly inhibited by quinin; atoxyl had a weakly inhibiting effect on all except thyroid. NaF suspended the action of hepatic, pancreatic and cardiac extracts; physostigmin suspended the action of these and also of aqueous humor and extracts of small intestine, iris, salivary glands, thyroid, brain, lungs, spleen, kidneys, suprarenals, skeletal muscle and thymus.

478. RABINOWITSCH, S. J. Der Ursprung und das Schicksal der Harnsäure und die Nucleinsäureresorption beim Hund nach der Angiostomiemethode. *Pflüger's Arch. Ges. Physiol.* 219(3/4): 402-406. 1928.—From the intestine nucleic acid is absorbed mainly in the form of nucleotides. After starvation, and normally, uric acid is produced in the various organs and therefore, with the exceptions of the blood of the hepatic and renal veins, venous blood contains more uric acid than arterial blood.—*S. J. Rabinowitsch (transl. by A. Spohn).*

479. SCHENCK, E. G. v. Über eine "Genealogie" der Eiweissstoffe. *Naturwissenschaften* 18(39): 824-828. 1 fig. 1930.—Biochemistry has devoted scarcely any attention to the dynamics of biological sequence in the cell, the phenomena of development, of senescence, of pathological degeneration, of nuclear distribution, etc. The investigation of this sequence would lead to a genealogy of the proteins in order to answer the question as to whether there was a transformation of individual structural substances (Baustoffe) during life corresponding to a transformation of form. The investigations on

the development of basic proteins in mature fish testicles (A. Kossel et al.) and the variations of globins in the aged and diseased have shown that alterations occur in the distribution of the amino acids and appear in orderly fashion in these proteins. The content of arginine rises during development and falls during senescence, inversely to the content of lysine and histidine probably; of the monoamino acids nothing is known as yet. As measured by their arginine content the proteins of young and immature cells possess a higher potential energy and a greater activity with reference to other amino acid complexes. Because the former draws the latter to itself, there follows during life a permanent loss of activity to the point of loss of solution-tension.—*E. G. v. Schenck (transl. by E. G. Young).*

480. SLONAKER, JAMES ROLLIN. Effect of different per cents of protein in the diet. I. Growth. II. Spontaneous activity. *Amer. Jour. Physiol.* 96(3): 547-556; 557-561. 1931.—I. Results of feeding 5 different percentages of protein (10-26%) in an otherwise well-balanced diet to 90 pairs of rats indicate that when best growth is considered the amount of protein in the diet should be slightly in excess of 14%. A deviation of 4% less or greater produced no serious results. In addition, as the per cents of protein increase beyond the optimum, there was a progressive retardation in growth. Indications are that similar results would obtain if the per cent of protein were reduced progressively below the optimum.—II. Groups of young ♀ rats (I, II, III, IV, V) were fed on diets containing 10, 14, 18, 22, and 24% protein respectively and the following results were found. (1) The number of days intervening from the time they were placed in revolving cages until spontaneous running began was least in the group receiving the lowest % and in general increased as the protein content became richer. (2) The order of magnitude of the different groups for the 1st few wks. of activity, from the highest to the lowest, was III, II, I, V, and IV. (3) The total distance run, from greatest to least, was group III, 2795 miles; II, 2735; V, 2683; I, 2622; and IV, 2546. (4) If allowance be made for activity lost incident to reproduction the order, from greatest to least, was group II, 4133 miles; III, 4097; I, 3803; IV, 3197; and V, 3110. (5) A diet containing between 14 and 18% protein is best suited to the albino rat for maximal spontaneous running.—*Author's summaries.*

481. STEPPUHN, O., und A. SMIRNOWA. Über die Beeinflussung des Eiweissumsatzes einzelner Organgewebe durch Schilddrüsenstoffe. *Biochem. Zeitschr.* 224 (1/3): 83-90. 1930.—The thyroid substance was either introduced dry into the alimentary canal by a feeding tube or injected subcutaneously into rabbits. The rabbits were bled and the liver, muscle, heart and brain examined for autolysis at pH 3.4, 7.4 and in water at 37°-38°; 4, with 5 controls, were studied after 48-hr. autolysis, and 3, with 2 controls, after 24 hrs. The conclusions are: In the determination of the autolytic intensity of individual tissue complexes in which thyroid has been removed or added in different ranges of acidity, it can be demonstrated how the increased or decreased nitrogen metabolism is distributed to the various organic tissues. The change in the nitrogen can be traced or followed in each separate organ. In a given case it could be shown that in the liver and cardiac muscle pulp especially, autolysis is diminished, while skeletal muscle protein is less affected and brain not at all. By these investigations a "biochemical injury" of the cardiac muscle proteins by thyroid toxicosis is established which can be connected with the well known phenomena of the functional cardiac injury in exophthalmic goiter. —*Authors' summary (transl. by V. G. Heller).*

482. TAKAHASHI, MASAO. The fate of hippuric acid in the chicken organism. *Jour. Biochem.* 10(3): 457-61. 1929.—Almost 90% of the hippuric acid fed to chickens was recovered unchanged in the urine, while 10% was excreted in the form of benzoic acid. Perfusion of chicken kidney and allowing mixtures of various chicken organs to stand with sodium hippurate solutions indicated that a large amount of the hippuric acid was split to benzoic acid and glycocoll by the kidney, but not so much by the liver or muscles.—*H. C. Koser.*

483. TERROINE, ÉMILE F., R. BONNET, R. CHOTIN, et GILBERTE MOUROT. Le rôle des sels ammoniacaux organiques, des albumines déficientes et des albumines efficaces dans la couverture de la dépense azotée endogène spécifique. *Arch. Internat. Physiol.* 33(1): 60-85. 1930.—Experiments were made on 6 pigs, 2 experiments for each class of dietary supplement. When a diet adequate in glucides, mineral substances and vitamins was supplemented by an NH_4 salt, by gelatin or by egg white, retention of N was observed. The addition of either NH_4 salt or of gelatin to the diet did not modify the excretion of total S, but the addition of egg albumin decreased the loss of total S as well as of N. Hence protein metabolism appears to be not indissolubly connected with total S metabolism; and, since the NH_4 salts act in this respect just like gelatin, there is no reason for denying to the former the rôle of protector against N deficit which is accorded to deficient protein substances. Creatinine excretion was unaffected by NH_4 salts, gelatin or egg albumin. Excretion of neutral S was unaffected by ingestion of NH_4 citrate or gelatin but increased by ingestion of egg albumin—another reason for not separating NH_4 salts from proteins in their effect on N metabolism. The excretion of creatinine and of neutral S was consistently and completely independent of the variations in N balance (even when the latter expresses only endogenous metabolism); creatinine and neutral S, then, are the indicators of distinct processes, and cannot be regarded as representatives of endogenous N metabolism.

CARBOHYDRATE METABOLISM

484. ALBERTONI, PIETRO. Sulle sedi di trasformazione degli idrati di carbonio nell'organismo animale. [On the seats of transformation of the carbohydrates in the animal organism.] *Rend. Sess. R. Accad. Sci. Ist. Bologna Cl. Sci. Fis.* 32: 148-150. 1927-1928(1928).—Glucose (20 gm. in 80 to 100 gm. H_2O) was introduced by stomach tube into rabbits which had not been fed for 24 hrs. At the end of 1 hr., the rabbits were killed, and liver and muscle samples were excised. The CO_2 production and O consumption of these tissues were compared with those of the same tissues excised simultaneously from control rabbits. The CO_2 output and O intake of liver tissue from the glucose-fed animals were higher than for the controls. The respiratory exchange of muscle tissues was unchanged. The writer concludes (1) that after a 20-hr. fast, the quantities of glucose fed are rapidly absorbed, held by the liver, and do not circulate; consequently, the respiratory exchange of muscle is not affected; (2) a given substance will differ in its effect upon tissue respiration according to whether it is placed merely in contact with the tissue or introduced by absorption from the alimentary tract.—*M. J. Lepore.*

485. ALTHAUSEN, T. L., LEWIS GUNTHER, JOHN B. LAGEN, and WILLIAM J. KERR. Modification of the dextrose tolerance test as an index of metabolic activity of the liver. *Arch. Internal Med.* 46(3): 482-493. 1930.—A method was devised consisting of the administration of insulin, dextrose and water followed by observation of the blood-sugar level over a period of 3 hrs. The advantages claimed are simplicity, harmlessness, reliability in individual cases as well as disease groups, independence of biliary obstruction, etc.

486. BICKENBACH, W., und P. JUNKERSDORF. Tierexperimentelle Untersuchungen über den Einfluss unphysiologischer Ernährung auf die Organzusammensetzung und das Stoffwechselgeschehen. *Arch. Exp. Path. u. Pharmakol.* 132(3/4): 129-144. 1928.—Four dogs were fasted 11 days and then given a pure fat diet for 2 to 5 days. Within 2 to 5 hrs. after fat ingestion a marked hypoglycemia occurred, followed by a sharp increase in blood sugar after a similar length of time. Total N in the urine was lowered, and NH_3 excretion was increased, during the fat-ingestion period. At the end of

this period glycogen and fat were determined in the heart, liver, and muscle tissue, and both moist and dry weights were obtained for a number of organs. Low glycogen and high fat content of the liver led to the conclusion that the changes observed in blood sugar were due to the interference of fatty infiltration with the glycogen-storing and blood sugar regulating function of the liver.—*M. Dann.*

487. **BLÖCH, JOSEPH. Über Beziehungen im intermediären Eiweiss- und Kohlenhydratstoffwechsel. I. II. III.** *Zeitschr. Ges. Exp. Med.* 74(3/4): 439-448; 449-453; 454-457. 1930.—I. In degenerative diseases of the liver with definite alimentary galactosuria, glycocoll administered simultaneously with galactose caused a diminished excretion of the latter. This effect is not caused by extrahepatic factors (decrease or delay of absorption, change of the renal threshold), but is the expression of an increased assimilation of galactose in the liver. The furtherance of the assimilation of galactose by glycocoll is connected with the glycogenetic activity of the latter. II. Alanine administered together with galactose to the glycogen poor liver with injured parenchyma was able to improve the assimilation of galactose. The presentation of sugar forming material to the glycogen greedy liver, at the same time with galactose, caused a better fixation and consequent assimilation of the latter. III. Asparagine also improved the assimilation of galactose by the injured liver.—*R. C. Corley.*

488. **BOLLMAN, JESSE L., and FRANK C. MANN. The physiology of the liver. XIX. The utilization of fructose following complete removal of the liver.** *Amer. Jour. Physiol.* 96(3): 683-695. 1931.—The injection of fructose into animals following complete hepatectomy is followed by a rise in the glucose content of the blood, and symptoms of hypoglycemia are prevented. If the stomach and intestines also are removed with the liver, conversion of fructose to glucose does not take place and the animal succumbs to hypoglycemia unless glucose is administered. Removal of the other abdominal viscera does not affect this conversion. In animals with intact livers but from which the stomach and intestines are removed, the process of converting fructose to glucose apparently is possible. Fructose is not utilized directly in the absence of the liver but is converted to glucose. The conversion of fructose to glucose may be accomplished in the intestines or in the liver but not to any appreciable extent in the other tissues of the body.—*Authors' summary.*

489. **CHIANELLO, CARLO. La simpatectomia della vena porta in rapporto alla funzione glicogenica ed alle modificazioni istologiche del fegato. [Sympathectomy of the vena porta in relation to the glycogenic function and the histologic changes in the liver.]** *Ann. Ital. Chir.* 9(4): 343-355. 3 fig. 1930.—In 24-72 hrs. after sympathectomy in 12 dogs (6 surgical, 6 chemical operations, the latter with phenol), Chianello found marked hyperglycemia, sometimes more than double the initial value. This hyperglycemia cannot be attributed to the narcotic used (morphine) for non-sympathectomized controls showed no rise in blood sugar after morphine narcotization. A slight hypoglycemia followed the hyperglycemia. The histologic changes in the liver comprised, in the early days, a slight congestion of the portal branches, the capillaries and the central vein, and a marked permanent dilatation of the capillaries, pyknosis of the cells and disturbance of the normal radiating arrangement of the cellular columns of Remak, lymphocytic infiltration, especially noticeable around the vessels of the portal spaces and the central veins, and progressive hypertrophy and hyperplasia of the perilobular connective tissue.

490. **DWORKIN, S., Z. M. BACQ, and D. B. DILL. The effect of regional sympathectomy upon muscle glycogen.** *Amer. Jour. Physiol.* 96(2): 308-310. 1931.—Preliminary determinations on 8 guinea pigs and 3 cats showed a fairly even distribution of glycogen between muscles of symmetrical and fore and hind limbs. Unilateral sympathectomy was done on 8 guinea pigs, 2 rabbits and 2 cats, and bilateral sympathectomy of either the fore or the hind limbs of 6 guinea pigs, 2 rabbits and 4 cats. The sympathectomized muscles in either case usually but not always gave a lower glycogen percentage, but the difference was seldom marked.

491. **FERRALORO, G. Ricerche sul ricambio degli idrati di carbonio in alta montagna. [Carbohydrate metabolism on high mountains.]** *Arch. di Sci. Biol.* 13 (1/2): 109-126. 3 fig. 1929.—Remaining at high altitudes increased blood sugar, probably owing to several factors, among them low barometric pressure, sun rays, hyperadrenalinemia. The assimilation threshold for glucose, as found by Aggazzotti, is higher. Perhaps this can be referred to a lowered permeability of the kidney, caused by hyperglycemia.—*A. Jappelli.*

492. **FISHBERG, ELLA H., and B. T. DOLIN. The intermediate metabolism of foreign sugars.** *Arch. Internal Med.* 46(2): 321-332. 1930.—A method is given for the separate determination of xylose and galactose in the presence of dextrose in 0.2 cc. of blood. The reducing nonfermentable fraction of the blood is remarkably constant in normal human beings, amounting to about 28 ± 5 mgm. %, while in uremia, diabetes, nephritis and lactation this is increased. Galactose and xylose introduced directly into the blood stream of rabbits disappear at a rate proportional to the actual concentration of the sugar in the blood in accordance with the law governing the velocity of a monomolecular equation. It is thus possible to calculate the nonfermentable reducing substance in the blood at any time, since the logarithm of the concentration of the sugar at any moment is proportional to the time after injection. Xylose disappears much more slowly from the blood stream of rabbits suffering from uranium nephritis and more quickly from rabbits made diabetic by phlorhizin. Galactose disappears more slowly from the blood stream of rabbits suffering from uranium nephritis and from the blood of those gradually poisoned by P. In human beings, galactose disappears more slowly from the blood of patients with nephritis and diabetes.—*Authors' summary.*

493. **HABS, HERBERT. Über das Verhalten der Kohlenhydratreserven bei vermindertem Luftdruck.** *Zeitschr. Ges. Exp. Med.* 72(3/4): 537-538. 1930.—The carbohydrate reserves of 18 rats from 3 litters and 10 white mice from a single litter were tested, 9 rats being kept several wks. at 470 mm. air pressure, and 5 mice for 36 days at 450 mm. The muscle glycogen, and still more the liver glycogen, were greatly decreased as compared with the controls.

494. **HOFFMANN, AUGUSTE, und ERNST WERTHEIMER. Stoffwechselregulationen. VII. Glykogenansatz beim künstlich gereizten entnervten Muskel.** *Pflüger's Arch. Ges. Physiol.* 216: 337-340. 1927.—Denervated muscle can deposit glycogen either in very small amounts or not at all (VI. Paper). A glycogen deposition in denervated muscle can be obtained by longer electrical stimulation. This artificially brought about glycogen synthesis is not nearly as large as that in the innervated control muscle. Glycogen synthesis in the muscle which leads to storage in the muscle glycogen depots is considered to be a reaction inseparably bound up with decomposition reactions.—*Authors' summary (transl. by G. T. Lewis).*

495. **KITASATO, TORAO. Weitere Synthesen von α Ketosäuren der Kohlenhydratreihe. α Keto-d-galaktonsäure oder d-Tagaturonsäure sowie α Keto-maltobionsäure oder d-Glucosido-d-fructuronsäure. 496. **OBRASZOW, G. D., M. N. KALLINIKOWA, und E. T. MINKER-BOGDANOWA. Zur Physiologie des intermediären Stoffwechsels bei Zuckerbelastung.** *Zeitschr. Ges. Exp. Med.* 72(5/6): 710-716. 8 fig. 1930.—The details of the experiments on which the following conclusions are based were published in Russian. This study concerns relations between sugar and fat, sugar and cholesterol, sugar and water, sugar and lipase, and

sugar and rest-N of the blood, with some control experiments. The subjects were normal or almost normal children, aged 8-14 yrs., number unspecified. In most cases a decrease in neutral fat, cholesterol, and amylase paralleled the hyperglycemia; there were also changes in lipase and rest-N. Besides the foregoing, most frequent, form of reaction, there were cases in which the other constituents of the blood were not changed when the sugar increased. The water content of the blood did not change under the sugar test. It seems probable that in this decrease in blood cholesterol, the organism makes use of a mechanism for regulating osmotic pressure and water in hyperglycemia. Rubner's law of isodynamy of nutritive substances apparently holds good also for the change in blood constituents after the sugar test.

497. OCHOA, SEVERO. Über den Tätigkeitsstoffwechsel kohlenhydratarmer Kaltblütermuskeln. *Biochem. Zeitschr.* 227(1/3): 116-134. 1930.—The carbohydrate metabolism of muscles of frogs rendered poor in carbohydrate by insulin was compared with the tensions produced in O and N. The K_{mo}-value of Semimembranosi is about 480. From this value and the carbohydrate utilization during resting respiration, it is seen that the tension work produced in muscles rendered almost carbohydrate-free by insulin can no longer be completely covered by the oxidation of carbohydrate. Under anaerobic conditions the lactic acid formed in the same case corresponds to the carbohydrate still present (considered 0.05 to 0.1%). But the K_{mL}-value is considerably too high. In this case the phosphagen splitting is relatively greater; it does not, however, provide any certain evidence that the amount of energy not accounted for by the lactic acid splitting is derived from the splitting of phosphagen. Nor could this be shown in a preparation in which, after exhausting the carbohydrate by slow anaerobic stimulation, the phosphagen was resynthesized in O, and then, in a second period in N, the production of tension, the phosphagen decomposition, and the lactic acid formation were determined.—*Author's summary (transl. by F. F. Heyroth).*

498. POPPER, HANS, und OSKAR WOZASEK. Zur Kenntnis des Glykogengehaltes der Leichenleber. *Virchow's Arch. Path. Anat. u. Physiol.* 279(3): 819-868. 4 fig. (2 col.) 1931.—The total carbohydrate content of the liver of human cadaver was determined on 177 persons according to the colorimetric method devised by Dische and Popper with indol and H_2SO_4 and the glycogen histologically according to Best. The comparison of both methods gave an approximate agreement between the total carbohydrate content and the detectable amounts histologically so far as the kernel glycogen was concerned. The liminal value at which the amount of glycogen was readily demonstrated in the histological picture lies at about ½% total carbohydrate. With persons dying suddenly without a preceding wasting sickness a total carbohydrate content of 1.56-6.17% was found with the exception of the separately discussed cases and considerable amounts of glycogen were recognized histologically. After a death struggle in a wasting sickness 0.24-1.53% was found. Accordingly there was little or nothing histologically. With persons who during a wasting sickness died suddenly, an intermediate value was found. Relations between the total carbohydrate content, the histological picture and different pathological changes of the liver, as well as the functional condition of the whole organism were studied and consideration was given also to the different forms of glycogen deposits. The findings on 22 cirrhotic livers of persons who died slowly showed values of 0.38-0.94%, therefore of approximately normal amounts. In proportion perhaps more glycogen was found histologically. The findings of 17 diabetics showed chemically 1.19-8.50%, essentially higher values than in deaths from chronic sickness, equally as much and perhaps more than the cases of acute death. Histologically glycogen was identified most abundantly. The findings of 26 kidneys showed values of 0.28-1.64%. Of these 13 were taken from diabetics and showed perhaps a higher content than the others. In 11 metastatic livers of different original growths 0.28-1.45% total carbohydrate was found, histologically no glycogen. A relation of the content of the liver to the manner of death was lacking. The studies are being continued particularly as regards diabetes mellitus and also with simultaneous direct determination of glycogen.—*Authors' summary (transl. by K. W. Buchwald).*

499. RALLI, ELAINE P., ATTILIO CANZANELLI, and DAVID RAPPORT. The respiratory quotient of proteins in pancreatic diabetes. *Amer. Jour. Physiol.* 96(2): 331-342. 1931.—According to a theoretical calculation, based on the assumption that the sugar deriving from protein was not oxidized, the respiratory quotient (R.Q.) of muscle protein in complete diabetes should be 0.73, of gelatin 0.65, and of casein 0.78. In depancreatized dogs [number not stated], given sufficient protein so that it could be assumed that the R.Q. of the animal was a function of the R.Q. of the administered protein, the authors found, after meat, a quotient of 0.72, av. starvation R.Q. being 0.71. They regard this as evidence validating the Minkowski ratio, and as opposed to (1), the theory that in pancreatic diabetes the primary defect is not the failure of the sugar oxidizing mechanism; (2) the theory that fatty acids are convertible to sugar. After administering gelatin, the av. R.Q. was 0.69, which the authors feel reasonably confirms their calculation for this protein. After casein, however, the quotient was consistently lower (0.70) than was expected from the theory. They cannot explain this discrepancy.—*Authors' summary.*

500. RIABUSCHINSKY, N. P. Zur Frage über die Beziehung zwischen der Milchsäure im Blut und der Ermüdung. *Pflüger's Arch. Ges. Physiol.* 226(1): 79-85. 1930.—Static work was performed by subjects until they were fatigued, the lactic acid in blood from the elbow vein being determined before and after the work. The "static work" was of two types: holding a weighted barrow and clasping a dynamometer. Only small increases in lactic acid were found during or after the work period, which lasted for 12 min. or less. The conclusions are drawn that (1) static work carried out even to complete fatigue does not itself cause an increase in lactic acid; (2) the formation and accumulation of lactic acid in muscles is not related to fatigue. A temporary stasis (10 min. or less) of the blood of the arm in a resting individual caused only a very small increase in the lactic acid of the blood.—*D. W. Wilson.*

None of these substances changed appreciably in quantity.—*L. Irving.*

502. SCHIFF, E., et al. Stoffwechseluntersuchungen über den Kreislaufshock. I. Blutzuckerregulation und Insulinwirkung. [E. SCHIFF, H. ELIASBERG, und A. MAZZEO.] II. Das Säurebasengleichgewicht. [E. SCHIFF, W. BAYER, und M. FUKUYAMA.] *Jahrb. Kinderheilk.* 128(3/4): 209-222. 7 fig.; 223-227. 3 fig. 1930.—I. This paper is based on an unspecified number of experiments on cats and dogs. Administration of dextrose to dogs after fasting and after peptone shock showed similar blood-sugar curves, which indicate that shock hyperglycemia is analogous to asphyxia hyperglycemia. Dogs were intravenously injected with insulin after 24-hrs. fasting and after peptone shock, the controls receiving insulin alone. In the controls hyperglycemia immediately set in; in the shocked animals, hyperglycemia preceded hypoglycemia; so long as the blood-pressure was sinking, the sugar content of the blood was rising, and with rise in the blood pressure the insulin hypoglycemia appeared, indicating that during

acute decrease of the amount of circulating blood, intestinal resorption was disturbed. In connection with pathologic study of clinical cases, these results indicate the probable cause of so-called intolerance of food in severe nutritional disturbances as an abnormal distribution of blood, giving an insufficient O supply to the digestive organs; also, that in circulatory shock there is, in addition to disturbed resorption, a disturbance of intermediary carbohydrate metabolism.—II. Peptone shock was induced in 4 dogs, and the blood pH, HCO_3, Cl, lactic acid, protein, total acid and total base determined before and after. The shock acidosis was found characterized by increased Cl, thereby resembling experimental anoxemia and toxicosis. The authors conclude that toxic acidosis is an anoxemic acidosis conditioned by circulatory shock.

503. SOLARINO, G. Sull'azione inibente dei polisaccaridi (amidi, inulina) sulla iperglicemia da glucosio. [Inhibiting power of polysaccharides on glucose hyperglycaemia.] *Arch. di Sci. Biol.* 13(1/2): 31-38. 1929.—Soluble starch from rice and wheat, administered to a fasting dog, caused slight hyperglycemia. Inulin produced also hyperglycemia, though less constantly, perhaps because of its slower hydrolysis in the stomach. If rice or wheat starch, also inulin, be administered after glucose, they prevent glucose hyperglycemia and glycosuria, perhaps through an increased internal secretion of the pancreas.—*A. Jappelli.*

504. USUELLI, FILIPPO. Stärkeaufnahme und Glykogenbildung der Panseninfusorien. *Wissensch. Arch. Landw. Abt. B. Tierernähr. u. Tierzucht* 3(1): 4-19. 1930.—In order to clarify the carbohydrate metabolism of sheep the dissolving of starch granules and glycogen formation in paunch infusoria were investigated, partly by addition of starch to paunch contents kept in a thermostat and partly by placing starch directly in the sheep's paunch. On an ordinary diet 16 hrs. after a feeding there are still to be found residues of the ingested starch in 3.25% of all infusoria in the paunch and glycogen deposition in 4.3%. After placing starch in the paunch or addition of it to paunch contents in the thermostat, the taking up of starch increases to a maximum in 4 hrs. and the glycogen formation in 6 hrs. In the paunch itself the disappearance of starch and glycogen formation were detectable in 76% of all infusoria after feeding corn starch. When starch (rice) was added to paunch contents in the thermostat, it likewise was taken up by the Infusoria and in 60% of the cases glycogen formation was found. Corn starch was taken by 54.35%, potato starch by 21.2% and wheat starch by only 12.9% of the Infusoria. Differences in the size of the starch grains can explain this difference in behavior of the Infusoria toward the several types of starch. Rice starch has the smallest grains and wheat and potato starch the largest. On separate administration of large and small grains of the same kind of starch, the large grains were 10% utilized and the small 50%. Experiments with mixtures of 2 or 3 types of starch grains showed that the size of the grains determined the behavior toward rice and wheat starch. By feeding sheep with different amounts of starch it was further shown that the taking up of the starch increased with the amount fed to a maximum. This is particularly apparent from the figures for the starch grains in the paunch contents both in and outside of Infusoria and from the ratio between them.—*Author's summary (transl. by G. T. Lewis).*

505. VERZÁR, F., und A. von KÚTHY. Die Erschöpfung der Insulinbildung durch Kohlehydratüberlastung. *Pflüger's Arch. Ges. Physiol.* 225(5/6): 606-612. 2 fig. 1930.—A series of experiments was carried out on 8 dogs for 4-20 weeks. The excessive administration of sugar daily for several weeks leads to the establishment of a condition, lasting about a week, in which there is mild glycosuria and hyperglycemia and a prolongation of the alimentary hyperglycemia curve. This indicates an exhaustion of insulin production as a result of the previously excessive demand for it. In so far as the investigations go, the results show that this form of experimental glycosuria is quickly recovered from and is entirely innocent in character. These findings are in harmony with the clinical experience that when the internal secretion of insulin has become exhausted, as in many cases of diabetes mellitus, it may recover either by restriction of diet or by administration of insulin.—*J. J. R. Macleod.*

506. VISSCHER, MAURICE B., and ARTHUR G. MULDER. The carbohydrate metabolism of the heart. *Amer. Jour. Physiol.* 94(3): 630-640. 2 fig. 1930.—It is found that hearts worked in the heart-lung preparation for periods up to 6 hrs. contain the same quantities of glycogen as are found in normal, unworked hearts. The mean value for a series of worked hearts does not vary significantly from the mean of normal hearts. It is improbable that work in the isolated heart-lung causes an appreciable lowering of heart glycogen. It is found that the free reducing substance in the heart muscle diminishes coincidently with the reducing substance in the blood supplying the heart of the heart-lung preparation. The free reducing substance in the heart may diminish to such a figure that it is probably nearly a zero value as far as glucose is concerned, while the glycogen content remains at a value similar to values obtained in unworked hearts. Comparison of the O consumption with the glucose utilization of the heart-lung preparation shows that in no instance does the heart-lung preparation, under the conditions of the authors' experiments, use heart glycogen or blood glucose for more than 60% of its metabolism, and in some instances these carbohydrates form less than 25% of the fuel. There is a rough agreement between carbohydrate burning as observed by the authors, and as others have calculated it from the respiratory quotient. All the carbohydrate in the system at the beginning of an experiment would not account for the total metabolism of the heart-lung over a period of 5 hrs.—*Authors' summary.*

507. WERTHEIMER, ERNST. Stoffwechselregulationen. XI. Mitteilung. Über die Sonderstellung der Eizelle im Stoffverbrauch. *Pflüger's Arch. Ges. Physiol.* 221(1/2): 119-138. 1929.—In the early months of the year the female frog has half of the total glycogen storage in the eggs, some 5 times as much as in the liver. In all possible changes in which the rest of the organism gives up practically all of its glycogen (heart, liver, muscles) (strychnin poisoning, adrenalin, heat and anoxybiosis) the eggs retain their glycogen. However, eggs cut out of the body present a marked glycogen loss.—*E. Wertheimer (transl. by H. J. John).*

508. ZUCKERKANDL, FRITZ, und LUISE MESSINER-KLEBERMASS. Über die Einwirkung von Tierkohle auf Glucose in Gegenwart dehydrierender Zwischenkörper. *Biochem. Zeitschr.* 226(4/6): 395-400. 1930.—Glucose alone, when warmed with animal charcoal, does not disappear, but does disappear on addition of para-phenylene diamine or other aromatic amines. Under these conditions a difficultly soluble condensation product is formed which is adsorbed by the charcoal. In a similar manner, glucose is acted upon by amino acids in presence of animal charcoal. In both cases, amino-groups are changed into imino-groups which have a dehydrating effect on glucose. The claim is made that under physiological conditions in the animal organism, quinone or imine-forming groups affect the glucose molecule. This reaction is the first leading to the break-up of glucose in the animal.—*Authors' summary (transl. by W. N. Berg).*

FAT METABOLISM

509. BLOOR, W. R., RUTH OKEY, and GEORGE W. CORNER. The relation of the lipids to physiological activity. I. The changes in the lipid content of the corpus luteum of the sow. *Jour. Biol. Chem.* 86(1): 291-306. 1 fig. 1930.—The percentage content of phospholipid of the corpus luteum of the sow has been found to vary markedly with the activity of the gland, being 2 to 3 times as high during the period of activity (previous to estrus and during pregnancy) as at the time of forma-

tion or after retrogression. Free cholesterol increases also up to and during the period of active functioning but to a much smaller extent. Cholesterol esters vary inversely with the activity of the gland, a high content being characteristic of the degenerated organ. These results support the hypothesis that the phospholipid content of this tissue is a function of its physiological activity. The relation of free cholesterol to activity is less clear, but appears to be similar to phospholipid. Cholesterol esters on the contrary seem to be related to inactivity or retrogression.—*Authors' summary.*

510. CANTONI, OSCAR. Ricerche sul preparato epato-pancreatico sopravvivente. *Biochim. e Terapia Sperim.* 17(8): 325-343. 1 fig. 1930.—In the surviving liver-pancreas preparation an artificial blood circulation was maintained by means of a heart-lungs preparation. The animals (dogs) were either kept fasting on the day before experiment, or they had an abundant fatty meal; in the second case the blood was drawn when lipemia had developed. In the fasting dogs the amount of fatty acids does not show variations during the whole experiment; it decreases, on the contrary, in animals showing lipemia. Qualitative variations follow in both series of animals: the melting and solidification points of the fatty acids decrease, whereby their I number is increased: a desaturation process has occurred. The blood cholesterol decreases in fasting dogs as well as in those showing lipemia. The O content of the blood is very high in the blood going to the liver and in that coming from it: on the contrary the CO_2 content is low, the respiratory quotient being accordingly less than 1. The blood urea content steadily increases during the experiment, in fasting as in lipemic animals.—*M. Comel.*

France.* 47/48(7): 756-758. 1930.—Milk, which is poor in Fe, Mn, Cu, etc., as well as in Zn, cannot meet for long the growth needs of a mammal. Soon the requirements must be met by a diet richer in metals. In the various species this point coincides with the natural time of weaning. This fact should be applied in human nutrition and a rational diet planned for the newborn.—*Authors' conclusions (transl. by M. Fay).*

518. BISHOP, W. B. S. The occurrence and possible importance of the metallic elements in biological material. *Jour. Cancer Research Com. Univ. Sydney* 1(4): 242-253. 1930.—A critical review of the literature, with bibliography.

519. BISHOP, WILFRID B. S. The occurrence of lead in the egg of the domestic hen. Part 2. *Med. Jour. Australia* 1(4): 96-99. 1929.—All eggs examined, from widespread districts, have been found to contain amounts of Pb ranging from 0.036 mgm. to 0.29 mgm. per whole yolk. The concentrations of Pb in wet shell, wet yolk, and white were also measured. An emu egg obtained in the natural state, had in 100 gm. of wet material 0.02 mgm. Pb for embryo, 0.75 mgm. for yolk, 0.025 mgm. for white, and 0.74 mgm. for shell. Pb in many eggs from the same fowl was determined for 3 fowls from different districts, and was found to vary within narrow limits. A fowl laying eggs containing a mean value of 0.12 mgm. of Pb per egg, had Pb in its tissues as follows: Leg muscle, 0.21 mgm. per 100 gm. of wet material; breast muscle, 0.19; femur, 0.94; complete brain, 0.17; blood, less than 0.005; ovaries, 0.52. Preliminary experiments indicate that the Pb is extractable from the yolks, and is capable of fractional distillation under reduced pressure, and also that it is precipitated with the $CdCl_2$ precipitate in the preparation of pure lecithin.—*W. B. S. Bishop.*

Gynäkol.* 96(2): 332-346. 1929.—In a large number of pregnancies, the urine and its Ca content were measured daily during the latter part of gestation up to parturition. The urine output curve was invariably lowered toward the end of the term; on the day of parturition it rose. Following this a more or less marked calcuria appeared, which is remarkable, in view of the simultaneous Ca loss in milk and lochia. The lowering of the blood Ca level, observed by other authors at birth, has been regarded as an expression of a sudden change of the metabolism. The additional idea is expressed that the pregnant woman protects herself doubly against these Ca losses first, by the heightening of the excitability of the breathing center, and second, thru the more ready production of ammonia.—*O. Bokelmann (transl. by H. J. John).*

521. CARPENTIER, G. Cuivre, acide urique, créatinine et travail musculaire. *Jour. Méd. Paris* 49(29): 613-615. 1929.—Rapid and intense muscular work for ½ hr. reduces the net elimination of uric acid in urine and augments the creatinine and creatine content of muscle. For any one subject it appeared that the product of the one times the other was a constant. Copper in a soluble form (acetate or sulphate) intensifies these phenomena through a catalytic action on oxidation.

For practical use in sports a dose of several centigrams is administered. Hypotheses and possible chemical reactions are considered.—*G. Carpentier (transl. by O. W. Barlow).*

522. **CARPENTIER, G. L'infiniment petit minéral et son action biologique. Le cobalt dans les eaux minérales** *Jour. Méd.* [*Paris*] 49(34): 715-717. 1929.—Traces of both Co and Cu are contained in certain natural waters. It is commonly believed that these minerals have a catalytic action on oxidation, reinforcing it. The bicarbonate of the waters has a reinforcing action on oxidation. —*G. Carpentier (transl. by O. W. Barlow).*

523. **CARPENTIER, G. La présence de traces infinitésimales de cuivre dans les eaux minérales. Eaux de Saint Nectaire (Puy de Dôme, France). Son rôle biologique.** *Presse Therm. et Climat.* 70(1): 37-43. 1929. —The renal and hepatic actions of water from the above source are not reputed to be due to the minute quantities of Cu which are present. This metal has a catalytic action on oxidations, thus resulting in a number of reactions which tend to detoxify the organism. Cu produces a diminution of the uric acid and augments the creatinine contents of the urine. Removed from the spring, however, the Cu was lost by precipitation. The author made a short chemical study of these properties of Cu and determined in addition the Cu content of the water.—*O. W. Barlow.*

524. **CLARK, H. W., and GEORGE O. ADAMS. Iodine in water, food and urine.** *Amer. Jour. Publ. Health.* 19(8): 898-900. 1929.—I content of water was less important than that of food in supplying I to the average individual. A method for determining I in urine is given, which would recover 75% of KI added to urine to an amount of 0.02 mgm. The authors concluded that since I in water furnishes a very small amount of the total I metabolized, the addition of I to drinking water is inadvisable.

525. **CLEMENTI, A. Carattere ureotelico del metabolismo azotato dei cheloni.** [Nitrogenous metabolism of turtles.] *Arch. di Sci. Biol.* 14(2): 171-181. 1929.—The urine of *Testudo* and *Emys* contains nearly as much urea as that of *Bufo*. Ammonia administration by mouth to *Testudo* and *Emys* caused a marked increase in the urea excreted in urine, contrary to what occurs in birds, the metabolism of which is uricothelic, i.e., the end-product is uric acid. These results show that nitrogenous metabolism of turtles, unlike that of other reptilians, is ureothelic, at least partially; in fact, not only urea is present in the urine, but administration of ammonia increases urea output. This exceptional nitrogenous metabolism can be explained by the fact that turtles are phylogenetically very close to the amphibians, involving related biochemical characters (ureothelic metabolism, arginase present in the liver).—*A. Jappelli.*

526. **COURTNEY, ANGELIA M., and ALAN BROWN. Calcium and phosphorus metabolism in some older children on mixed diet including a large or a small quantity of milk.** *Arch. Dis. Childhood* 5(25): 17-22. 1930.—Two boys and 2 girls were fed mixed diets including a large quantity of milk, and 2 other boys and 2 other girls a corresponding diet containing very little milk. Food, urine and feces were collected quantitatively for 4-day periods and analyses were made for fat, Ca, Mg and P to determine the excretion and retention of these constituents. The low milk diets, even with inclusion of eggs and vegetables, were found to provide far too little Ca and P for the necessary retention of these elements. The results were found to fall into 2 distinct groups for each kind of diet. In 1 group on each Ca and P level the excretion of Ca and P, except urinary P, on the low intake, was much less than in the other on the same diet and the retention correspondingly better. The large urinary excretion of P in group 3 is difficult to explain. These observations afford evidence that children on the same diet and apparently in equally good condition can on occasion differ so materially in their metabolic processes that 1 may lose through the feces far larger amounts of Ca and P than the other even to the point of suffering a serious loss to the body when the intake of these elements is low.—*Authors' summary.*

527. **COURTNEY, ANGELIA M. Some studies on calcium and phosphorus concentration in the small and large intestines of children.** *Arch. Dis. Childhood* 5(25): 23-27. 1930.—The results here reported indicate that there was greater excretion or less absorption of Ca than of P in the large intestine in all the children studied. It also appears probable that the Ca concentration in the large intestine was due in considerable proportion to Ca not bound to P. In children with abnormal intestinal conditions there was much less difference between the contents of the large and of the small intestine in both Ca and P concentration than in those without intestinal symptoms.—*Author's summary.*

Jour.* 23(6): 1328-1345. 4 fig. 1929.—During prolonged rest there is a rise in the excretion of S, N, P and Ca for a varying period and then a gradual decline. The rise in the excretion of S is in inorganic sulphate while the rise in N is in urea. The maxima and minima percentage day to day variations in the O consumption gradually decrease from ± 14% to ± 1.2%.—*E. B. Carmichael.*

529. **DILLELA, GILBERTO G. Chimica physiologica da pelle.** *Rev. Med.-Cir. Brasil.* 37(10): 435-441. 1929.—A review of recent work on the subject with special reference to metabolic changes in the skin.

530. **EFIMOFF, W. W., und K. S. SAMITSCHKINA. Zur Biochemie der Ermüdung. Einwirkung der Gewerbearbeit und der Erholung auf die Alkalireserve und den Gehalt an Phosphor im Blut nach Untersuchungen an Spinnerinnen.** *Arbeitsphysiologie* 2(4): 341-346. 1929.—Women, 20 to 40 years of age, worked at spinning either 10 hrs. continuously, or 2 shifts of 5 hrs. each with a 6 hr. rest period between, or 6 hrs. on alternate days. Blood samples were taken before and after the working day. In the 10-hr. group of 7, all but 2 who slept 2½ to 3 hrs. in the rest period showed after the work a lowering in the alkaline reserve from 8.2 to 14.6%, and an increase in the inorganic P from 5.7 to 46.3% of the prework levels. Similarly, in all but 1 of 10 on the 6-hr. day, the alkaline reserve was lowered by work 4.0 to 19.8%, and the inorganic P was increased 6.7 to 79.1% of the prework values. There was no correlation between the lowering of the alkaline reserve and the increase in the inorganic P. A study of recovery in 3 subjects from whom samples were taken at 0, 30, 60 and 90 min. after work period showed that the return to normal was slow and was not complete in 1½ hrs. All the women gave subnormal alkaline reserve values at the beginning of the day, indicating a chronic fatigue that was ascribed to unfavorable conditions of living.—*T. M. Carpenter.*

531. **EIMER, KARL, und WERNER VOIGT. Rohkoststudien. I. Der Einfluss der Rohkost auf den Wasser- und Kochsalzhaushalt des Gesunden.** *Zeitschr. Ges. Exp. Med.* 69(5/6): 679-701. 1930.—At the beginning of the raw diet period the 2 healthy subjects suffered considerable loss of weight (loss of water almost exclusively, due apparently to low NaCl content of food), after which the body weight remained constant. The raw diet furnished only about 2 gm. NaCl daily, as against about 13.5 gm. in a standard mixed diet. During the raw diet period the NaCl excretion in the urine sank to a minimum (about 0.5 gm. daily). The raw diet seemed to be admirably adapted to sparing the kidneys.—*From authors' summary (transl.).*

532. **GOERNER, ALFRED. The effect of colloidal and crystalloidal metallic compounds in nutritional anemia of the rat.** *Jour. Lab. and Clin. Med.* 15(2): 119-121. 1929.—White rats (number not stated) were rendered anemic by a diet of powdered milk and distilled water. To this diet solutions of metallic compounds were then added. It was found that salts of Mn as well as of Cu are capable of increasing the hemoglobin of anemic animals when these salts are added to Fe salts. Pure Fe salts in solution have not the same pronounced effect.

Salts of Zn and Al when added to Fe salts fail to elicit any marked hemoglobin increase. Colloidal solutions of Mn and Cu in the presence of colloidal solutions of Fe have not this hemoglobin-producing power when administered in comparable quantities, nor have the former the power of preventing the reduction of hemoglobin when the animals are placed on a diet capable of producing severe anemia.—*Author's summary.*

533. **GOSS, HAROLD, and CARL L. A. SCHMIDT. Calcium and phosphorus metabolism in rats during pregnancy and lactation and the influence of the reaction of the diet thereon.** *Jour. Biol. Chem.* 86(1): 417-432. 9 fig. 1930.—Calcium and P balances in the rat were carried out through continuous periods of rest, pregnancy, and lactation. During 27 completed pregnancy periods, on the various diets, only 4 failed to show a positive balance of Ca and only 3 failed to store P. In most cases the positive balance was in excess of that estimated to be contained in the young at birth. In 17 lactation periods, all showed a negative balance of Ca and all but one a loss of P. The losses for full sized litters were as great as 20% of the entire body content of these elements in the mother. Within the range of acidity employed, no significant difference could be found between the diets, except that the 2nd litters from the rats on the diet containing $NaHCO_3$ were not nourished by the mother, due to failure to lactate. Young rats from mothers which had been maintained on acid alkali were kept for some time on these respective diets. No difference in storage of Ca and P was noted. Females reared on a vitamin E-free diet stored Ca and P during the period of pregnancy in which resorption of the fetus took place.—*Authors' summary.*

534. **HAMILTON, BENGT, and MARGARET MORIARTY. Factors influencing the excretion of calcium.** *Amer. Jour. Dis. Children* 36(3): 450-462. 2 fig. 1928.—The normal variations in the excretion of Ca in the stools of breast-fed infants were studied. The Ca excretion was influenced chiefly by the intake of fixed base and, to a lesser degree, by the intake of Ca. Since total fixed base is closely related to the buffer content of the milk, it is suggested that the latter is the controlling factor in the excretion of Ca. In support of this view it is found that the addition of alkali to the milk increases the excretion while the addition of acid decreases it.—*L. A. Maynard.*

535. **HAYASHI, HIROKICHI. Untersuchungen über Cetacea. XXIX. Über Alkalien und alkalische Erden in verschiedenen Horngeweben. Ein Beitrag zur Frage der Keratinisation.** *Japanese Jour. Med. Sci. Trans. II. Biochem.* 1(2): 137-149. 1927.—The skin from the head and the tail, mucous membrane from the first stomach and the beard of whales were analysed for fat, N and ash. Sodium, K, Ca and Mg were determined in the ash, and it was concluded that the presence of a large proportion of the last 2 elements is related to the process of keratinization. The ratio of alkalis to alkaline earths in serum of whales is 20 : 1 while in the beard it is 1: 1.—*D. B. Dill.*

536. **HENDERSON, JOHN McASKILL, and FRANCIS CHARLES KELLY. The influence of certain dietary supplements in relation to the calcium requirements of growing African natives. II.** *Jour. Hyg.* 29(4): 429-438. 1930.—Of 5 experimental subjects—growing East African native boys—4 had definitely negative Ca balances on the diet in use at the Nairobi Prison, while the 5th was merely in Ca equilibrium. The diet in question was found low in Ca (0.32 gm. Ca per day). These negative Ca balances became positive on the addition of Ca as milk, or in a mineral mixture, with or without cod-liver oil. Cod-liver oil alone was not effective in bringing about any appreciable reduction of a negative balance. 0.43 grm. Ca daily was the maintenance requirement for the subjects under experiment; this figure is practically the same as that found by Sherman for white races. On giving additional Ca in a mineral mixture it was found that after the maintenance requirement had been satisfied, as much as 50% of any excess might be retained. The Ca of milk, on the other hand, was found to be utilized more efficiently; the corresponding retention figure being over 70%. The influence of the various supplements on growth is briefly discussed.—*Authors' summary and conclusions.*

537. **HENDERSON, JOHN McASKILL, and FRANCIS CHARLES KELLY. A note of the influence of the addition of certain supplements to the diets of African natives. III.** *Jour. Hyg.* 29(4): 439-442. 1 fig. 1930.—Both control and experimental groups showed increases in weight during the early part of the experiment. The 2nd group, when minerals and cod-liver oil were added to the diet, showed definitely greater increases of weight, and a falling off when these were withdrawn. Cod-liver oil added to a basal diet did not result in positive Ca balances when the subjects had previously had negative balances. Mineral and cod-liver oil added together, or milk added to the basal diet, did produce positive Ca balances.

538. **HESSE, ERICH. Aufnahme und Ansatz von Kalk-Phosphor bei normalen und rachitischen Tieren.** *Arch. Exp. Path. u. Pharmakol.* 147(1/3): 173-192. 1929.—To determine the amounts of Ca and P compounds absorbed, dogs were fed; after 24 hours the dogs were killed, the esophagus and small intestine were tied off and their contents analyzed. From Ca malonate or a mixture of this with sodium phosphate about ⅓ of the Ca and ½ of the P were absorbed. If the Ca was given in a gum emulsion the absorbed fraction was raised to 75%. From a phosphatid-containing emulsion about half the Ca malonate was taken up. The phosphatid disappeared quantitatively from the gastrointestinal tract in 8 hrs. Strange to say the soluble gluconate and calipot, which is a mixture of Ca citrate and Ca glycerophosphate, were absorbed no better than the insoluble Ca malonate. To determine the retention, normal and rachitic rats were fed with Ca salts over longer periods and then analyzed in toto. Such animals, as well as those receiving vitamin before being made rachitic, stored about 10% of the ingested Ca.—*E. Hesse (transl. by C. S. Robinson).*

539. **HUFFMAN, C. F., C. S. ROBINSON, O. B. WINTER, and R. E. LARSON. The effect of low calcium, high magnesium diets on growth and metabolism of calves.** *Jour. Nutrition* 2(5): 471-483. 2 pl. 1930.—Magnesium phosphate when fed to calves on low Ca diets produced no apparent harmful effect. $MgCO_3$ added to a diet low in Ca but adequate in P caused immediate improvement in general condition and in Ca and P utilization of a calf, which persisted until after the $MgCO_3$ had been again withdrawn. Improved Ca and P balances were also induced by addition of $MgCO_3$ to the diet of 3 cows. Either carbonate or phosphate increases the storage of Mg.—*E. L. Batchelder.*

540. **ISEKI, TOSHINORI. Über das Verhalten der anorganischen Bestandteile bei der Bebrütung des Hühnereies.** *Hoppe-Seyler's Zeitschr. Physiol. Chem.* 188 (3/5): 189-192. 1930.—In a late stage of incubation the Ca content of the egg proper increased; that of the shell decreased. Thus the shell furnished some building material for the embryo. In the early stages of incubation the alkali metals, sulphates and chlorides were present in greater quantity in the egg white than in the yolk. On the 7th day of incubation the alkalis of the yolk suddenly increased and at the same time the chlorides and sulphates also increased; they decreased, however, in the egg white. The alkalis passed through the yolk sac into the yolk in mobile form. From the yolk they were taken up by the embryo.

541. **JARVIS, NORMAN DONALD, RAY WILLIAM CLOUGH, and ERNEST DUNBAR CLARK. Iodine content of the Pacific coast salmon.** *Univ. Washington Publ. in Fisheries* 1(6): 109-140. 1926.—131 samples of canned and fresh salmon were analyzed for I. The I content of canners' salt was also determined. The I content of canned salmon is compared with that of such foods as butter, milk, meat, vegetables and cereals, showing that canned salmon contains much more I than any of these

products. Charts are given showing the relative I content of the different species and variation by district within the species, as illustrated by the king or chinook salmon. Different parts of the same fish vary in I content, the parts of the flesh richest in fat apparently having the most I. The milt and roe are especially rich in I.—*Authors' summary.*

542. KAPLANSKI, S., und N. TOLKATSCHEWSKAIA. Über die Wirkung der Säuren und Alkalien auf den Mineralstoffgehalt der Gewebe und des Blutes. II. *Zeitschr. Ges. Exp. Med.* 69(5/6): 748-757. 1930.—In 8 rabbits 10 cc. of a 10% $NaHCO_3$ solution was injected intravenously. An hour later the mineral content of the blood had returned to normal, but the mineral content of the skin had altered significantly, the cations being increased, the Cl decreased. Long-continued introduction of alkali by mouth (1 rabbit) produced in both blood and skin an increase in cations and still more in Cl, constituting a displacement of the cation-anion equilibrium to the acid side. Intravenous and peroral introduction of acid (10% NaH_2PO_4 solution) also produced an increase in the Cl of the skin, with a constant percentage of Na, K and Ca.—*Authors' summary (transl.).*

543. KORIAKINA, A. F., E. B. KOSSOWSKAJA, und A. N. KRESTOWNIKOFF. Über die Schwankungen des Chloridgehaltes im Blut, Harn und Schweiss bei Muskeltätigkeit. I. Mitteilung. *Arbeitsphysiologie* 2(6): 461-473. 1930.—The concentration of chlorides in the blood, urine and sweat was determined before and after the following contests: 144 km. bicycle ride, 13.5 km. race, 28 km. race, 3 km. race (women), football playing, and 45-60 min. work on a bicycle ergometer. There was a rise in blood chloride shortly after beginning work or after the conclusion of a short period of activity. A fall occurred after activity of longer duration. In the urine, the chloride rises at the beginning of work, but subsequently falls. The magnitude of the fall in blood and urine chlorides is in direct relation to the intensity and duration of the activity; the longer and greater the intensity of work, the greater the decline. Chlorides appear in the sweat as a rule; though with a low level of chlorides in the blood, no chlorides appeared in the sweat.—*T. M. Carpenter.*

544. KRANTZ, JOHN C. JR. The use of sodium malate combinations as a dietary substitute for sodium chloride. *Ann. Internal Med.* 3(8): 826-834. 1930.—A mixture of sodium malate 85.5%, sodium citrate 9%, ammonium citrate 5% and manganese bromide 0.5% was found to possess a saline taste practically identical with that of sodium chloride. The metabolism of this mixture was studied when administered to dogs and man. The anions were found to be metabolized, the essential influence upon ingestion was a change in the acid-base equilibrium of the urine. Upon the ingestion of 4 gm. daily the urine changed from pH 6 to pH 7. The mixture is recommended for use in the salt-restricted diets prescribed in nephritis, hypertension and edema.—*J. C. Krantz, Jr.*

545. LANG, THEODOR. Die Gefahr der Demineralisation und Transmineralisation unserer Nahrungsmittel. *Schweiz. Med. Wochenschr.* 60(10): 219-223. 1930.—The author determined the Na, K, Ca, and P content of white cabbage, red beets, peas, carrots, tomatoes, and cauliflower. The Na: K ratio of these fresh vegetables ranged from 1: 0.34 for cabbage to 1: 34 for cauliflower. The Na: Ca ratio for peas was 1: 0.61; for white cabbage 1: 1.58. Cooking produced a large loss of K; the loss of Ca was not great. The manner of preparing and cooking potatoes determined their salt loss, and also their basic and acid equivalents. Potatoes cooked in salty water lost a great deal of K; potatoes unpared and cooked in a little water retained most of their minerals.

546. LINTZEL, W. Zur Frage des Eisenstoffwechsels. Nachtrag zur IV. Mitteilung. Ueber das Harneisen. *Zeitschr. Biol.* 89(4): 350-352. 1929.—By the method of Henriques and Roland for the determination of Fe in urine, other substances oxidizable by titanic trichloride which, in treating the previously ashed solution with strong oxidizing agents, remain behind are titrated with and estimated as Fe. The urine Fe values found by Henriques and Roland are thus too high. By the use of absolutely Fe-free reagents whose preparation has been described, no red coloration of the solution from urine ash is seen with KCNS. On the basis of the sensitivity this reaction yields, less than 0.02 mgm. Fe per l. was present in the urine of the ♂ subject.—*W. Lintzel (transl. by H. H. Riecker).*

547. LINTZEL, WOLFGANG. Zur Frage des Eisenstoffwechsels. V. Mitteilung: Ueber den Eisenbedarf des Menschen. *Zeitschr. Biol.* 89(4): 342-349. 1929.—A new, rapid and practical method for the estimation of the Fe content of the feces is described by which the feces are collected in a 2 l. porcelain dish, triturated with H_2O and put through a porcelain filter. Aliquot portions of the residue are pipetted off and ashed and the Fe is determined colorimetrically with NH_4CNS. In the case of a ♂ subject, fed an Fe-poor diet consisting mainly of rice, egg-white and butter, the Fe content of the food was regulated at 0.9 mgm. to maintain the balance of Fe intake and Fe output. A greater elimination of the end products of Fe metabolism was therefore not present. Also in the case of an intake of 63.8 mgm. Fe daily an approximate balance of intake and output was brought about after a period of retention. The Fe demand of the adult is estimated to be less than 0.9 mgm. per day if special conditions such as pregnancy, training, and residence in high climates are excluded.—*W. Lintzel (transl. by H. H. Riecker).*

548. LOHMANN, K. Über das Vorkommen und den Umsatz von Pyrophosphat in Zellen. II. Mitteilung: Die Menge der leicht hydrolysierbaren P-Verbindung in tierischen und pflanzlichen Zellen. *Biochem. Zeitschr.* 203 (1/6): 164-171. 1928.—The amount of pyrophosphate was determined in striated muscles and other organs of vertebrates and invertebrates, in yeasts, and in the roots of certain plants. The muscles contain 0.5 to 1.0 mgm. P_2O_5; bakers' and brewers' yeasts 1.6 to 1.8 mgm. P_2O_5 per gm. In the tissues of frogs and rabbits the amount of P_2O_5 varied from 0.1 to 0.4 mgm. per gram moist weight. The pyrophosphate in roots of peas amounted to about 10% of the total acid phosphates.—*M. C. Sewell.*

549. MACY, ICIE G., HELEN A. HUNSCHER, SYLVIA SCHIMMEL McCOSH, and BETTY NIMS. Metabolism of women during the reproductive cycle. III. Calcium, phosphorus, and nitrogen utilization in lactation before and after supplementing the usual home diets with cod liver oil and yeast. *Jour. Biol. Chem.* 86(1): 59-74. 1930. —Ca, P, and N balances were determined on 3 nursing mothers before and after supplementing their customary home diets with cod liver oil and yeast. Daily feedings of 15 gm. of cod liver oil and 10 gm. of yeast over a period of 2 mos. when the milk flow persisted at its highest rate stimulated better Ca and P utilization in all cases. During the experimental period the Ca and P assimilation was greatly improved. The decrease of fecal excretion of both Ca and P, absolutely and relatively, during the experimental period illustrates a marked alteration in metabolism and accounts for a greater assimilation of these elements. The N metabolism was inappreciably altered during the interval of observation. These lactating women experienced a more economical utilization of their available food constituents and a greater feeling of well being after the addition of cod liver oil and yeast to their home diets.—*Authors' summary.*

550. MAURER, E., und H. DUCRUE. Zur Kenntnis des Jods als biogenes Element. XIX. Mitteilung. Der Jodgehalt im normalen tierischen Organismus. *Biochem. Zeitschr.* 217(1/3): 227-230. 1930.—The I content of the thyroid was no indicator of the I content either of the organism as a whole or of particular organs. The I content of most of the organs of normal rabbits is shown in tabular form.

551. MAZZOCCO, P. El iodo en el aire, rocío, suelo y agua de Salta. [Iodine content of air, dew, soil and

water of Salta.] *Rev. Soc. Argent. Biol.* 5(5/6): 440-462. 2 fig.; El iodo en los alimentos de Salta. [Iodine content of food in Salta.] *Rev. Soc. Argent. Biol.* 5(5/6): 463-471; MAZZOCCO, P., y C. ARIAS-ARANDA. Contenido en iodo de las tiroides de ovinos de Salta y litoral. [Iodine in sheep thyroids in Salta and on the seacoast.] *Rev. Soc. Argent. Biol.* 5(5/6): 472-485; Metabolismo del iodo y profilaxis del bocio en Salta. [Iodine metabolism and goiter prevention in Salta.] *Rev. Soc. Argent. Biol.* 5(5/6): 486-497. 1929.—Numerous analyses of I content in air, soil, water, food, thyroids, etc., were made in Salta (a goiter district) and in Buenos Aires (a non-goiter district). In Salta the I content was generally much smaller than in Buenos Aires; wherever the percentage of goiter was highest, the I content was lowest. The food intake of more than 400 persons in Salta was studied and the I intake was determined; it was found to be between 22 and 26 micrograms per day. The foods preferred are maize and meat, both poor in I. These facts justify goiter prophylaxis by I administration.—*J. T. Lewis.*

552. MORACZEWSKI, W. von, und W. SKOWRÓNSKI. Wasserausscheidung des Kaninchens bei Hafer- und Rübennahrung. *Zeitschr. Ges. Exp. Med.* 69(1/2): 86-93. 1929.—The number of rabbits used is not stated. Some were on a fat-rich diet (70 gm. oats = 200 calories, daily) and the others on a fat-poor diet (400 gm. fresh turnips = 120 calories, daily). This amount of turnips contains about 340 gm. water; the oat-fed rabbits received 300 cc. water daily additional, introduced directly into the stomach by a catheter. This water was retained in part, or, if the diet contained salt, altogether. The oat diet by itself tended to cause anuria, while the introduction of 300 cc. water caused renal shock. The water retention increased as the amount of water given with the oats increased. An addition to the oat diet of the mineral salts present in turnips caused a decrease in the water excretion. Dried turnips or carrots given with enough water to supply the deficiency produced no water retention such as was observed from the oat diet. Pituitrin injection caused a marked water retention in the rabbit on the turnip diet, but had no such effect when given with the oat diet; thyroid extract, however, given with the turnip diet produced a much more abundant diuresis than when given with the oat diet. Insulin is a diuretic with the turnip diet; with the oat diet it tends to urinary retention. Euphyllin produces an important increase in urinary excretion with turnip diet; with oat diet it increases NaCl excretion, but not that of water.

553. MUTTKOWSKI, R. A. Insect nutrition and metabolism. *Ann. Ent. Soc. America* 22: 552-554. 1929.—Corrections to Uvarov's Insect Nutrition and Metabolism (1928). Uvarov misquotes the author on the rôles of arsenic and lead, attributing functions directly opposite to those given in the original paper (1923).—*R. A. Muttkowski.*

554. REMINGTON, ROE E., and H. E. SHIVER. Iron, copper and manganese content of some common vegetable foods. *Jour. Assoc. Offic. Agric. Chem.* 13(1): 129-132. 1930.—Data are presented for the Fe, Mn, and Cu content of a number of samples of 18 kinds of vegetables used as food. The methods of analysis were checked on known quantities of the element sought. The results are discussed in the light of previously published data, and from the standpoint of the value of these vegetables in nutrition. When compared with root and fruit vegetables, the green leafy vegetables were found to be outstanding as sources of Fe, Mn, and Cu.—*Authors' summary.*

555. ROMINGER, E., IMRE BERGER, und HUGO MEYER. Klinisch-experimentelle Untersuchungen über die Beziehungen zwischen Wasser- und Kochsalzumsatz beim gesunden Säugling. *Zeitschr. Kinderheilk.* 48 (1): 43-66. 1929.—Investigations were done on infants 1 to 5 mos. old. To a definite basic diet 2 to 5 gm. of NaCl per day were added. It was found that regularly a part of this was retained by the body and after discontinuing this dose it was gradually excreted. Occasionally the salt caused retention of water, but there was no relationship between the quantity of retained water and the quantity of NaCl, and sometimes the retention of NaCl was without water retention. These experiments add further proof to the view previously expressed by the authors that water and salt in the organism of the infant have little relation to each other. —*E. Rominger* (*transl. by H. J. John*).

556. SAGARA, JUN-ISCHIRO. Über die Bildung der Hexon- und Purinbasen bei der Entwicklung des Hühnereies. *Hoppe-Seyler's Zeitschr. Physiol. Chem.* 178(4/6): 298-301. 1928.—Chick embryos of 14 days incubation were macerated into a paste from which the fat was subsequently removed with ether. Extraction of purine bases was accomplished according to the method of Stendel. The developing chicks showed a marked increase of free hexone bases, especially arginin and lysin, the latter in excess. A neo-formation of purine bases was noted.—*N. A. Michels.*

557. SCHARRER, K., und J. SCHWAIBOLD. Zur Kenntnis des Jods als biogenes Element. XVIII. Mitteilung. Über die Art der Bindung des Jods in der Milch. *Biochem. Zeitschr.* 207 (4/6): 332-340. 1929.—Milk as a rule contains I but only a small proportion of this element is bound in the inorganic form. The albumin, fat and sugar of milk are relatively deficient in I. The protein binds a small and variable quantity. The fat contains generally either no I or a negligible quantity. This relation varies little following the administration of iodized albuminates. Can such compounds be retained or be excreted in the milk? Following the administration of massive doses of NaI, a noticeable and comparable rise in the I content of the milk occurs. Subsequent to feeding iodized fatty acids, the major portion of the I appears in the milk as glycerides.—*O. W. Barlow.*

558. SCHULTZ, ROBERT V. A study of certain effects in the rat produced by diets deficient in mineral salts. *Yale Jour. Biol. & Med.* 2(2): 115-122. 1929.—A group of 12 ♀ albino rats were kept for 40 days, starting from weaning, at or near stationary body weight by feeding a diet deficient in mineral salts; a similar group of 10 were killed at weaning; a 3rd group of 10 were fed an adequate diet for 40 days from weaning, during which time the weights tripled; the treatment of 2 other groups of 10 each was suggested by developments to be described. The bones of the low-salt group were markedly fragile, the fat-free bone ash contents were low, and the bone-moisture contents were high, like those of infantile bones. The body and tail lengths were markedly stunted in this group, the erythrocyte count was remarkably high, and the spleen small. To determine if the latter conditions resulted from specific deficiency or from the incidental stunting, 10 ♀ rats were maintained at about stationary weight by underfeeding. The spleens in the underfed animals were reduced in size as compared with the normal rats, but were about 1½ times heavier than those of the low-salt group. To determine whether splenectomy would influence the polycythemia produced by a low-salt diet, 10 ♀ rats were splenectomized and fed salt-poor food, with slight effect on the numbers of erythrocytes. This increase in red cells did not occur in the underfed rats.

559. SCHWARZ, L. Einfluss der Ernährung auf die Eisenspeicherung der Leber und Milz der weissen Maus. (Beitrag zum Eisenstoffwechsel.) *Virchow's Arch. Pathol. Anat. u. Physiol.* 269(3): 638-662. 5 fig. 1928.—Fe fed was deposited only in the liver cells, none in the stellate cells. Histological and chemical analyses gave parallel values, and a threshold value for diffuse and granular deposit was obtained. The degree of storage depended upon both the kind of diet and the condition of the cell. The liver cells of undernourished animals stored more Fe than those of meat fed animals, thus confirming findings of older investigators. Feeding of reduced Fe gave no deposit in the stellate cells. The spleen served as a secondary deposit for Fe fed.—*H. H. Riecker.*

560. SCHWARZ, L. Zur Frage der Eisenspeicherung und des Eisenstoffwechsels. *Verhandl. Deutschen Ges. Innere Med. Kongress* 40: 604-609. 1 fig. 1928.—Chemical and histological examinations indicate that mice on a high-protein diet store less Fe (in the liver) and eliminate more than those maintained on a starvation or low-protein diet.—*G. W. Pucher.*

561. SPEED, KELLOGG, and DEAN L. RIDER. Experimental healing of bone after parathyroidectomy. *Arch. Surg.* 21(4): 679-692. 7 fig. 1930.—A study of serum Ca alone in dogs shows merely the height of the Ca in the stream of balance; it does not give any indication as to the direction of its flow, whether into excretory channels or into the bones. On 4 parathyroidectomized dogs in which tetany was controlled by the use of Ca lactate and thyroid extract, determinations of the Ca content of the excreta were made. The lack of calcification of the bones after experimental fracture, in conjunction with the low blood Ca, led to the inference that the Ca stream was directed away from the bones after parathyroidectomy, and that parathyroidectomy, either through this change of the Ca stream or through some still undiscovered factor, delays the healing of fractures.—*Authors' conclusions.*

562. STRAUB, JOHANN. Über die Verbreitung des Kropfes in Ungarn und dessen Zusammenhang mit dem Jodgehalt der Trinkwässer. *Zeitschr. Hyg. u. Infektionskrankh.* 111(4): 472-479. 1930.—So far as the school population is concerned, the Hungarian basin, comprising the greater part of the country, is goiter-free; but goiter occurs locally in Transdanubia and Upper Hungary (in 11.5 to 59.3% of school children). The drinking water of the goiter-free basin, derived from artesian wells and deep springs, has a large percentage of I (av. 76.8 γ per liter). The water in the goitrous regions, where derived from surface sources, is invariably poor in I (0-2.1 γ per liter); where derived from artesian wells and deep springs is poorer in I than that in goiter-free plain. But there is no difference between the I content of the drinking water (except from some artesian wells) of the goitrous and goiter-free localities in Upper Hungary and Transdanubia. The artesian wells and deep springs are generally characterized by alkalinity (Na_2CO_3 or $NaHCO_3$), the I content varying more or less with the alkali content. Straub remarks that the fact of the coincidence of goiter-free spots with I-poor water does not necessarily contradict the theory of the causation of goiter by I insufficiency; for in these localities the I needs of the population may be supplied by the food.

563. STURM, ALEXANDER. Beiträge zur Kenntnis des Jodstoffwechsels. 3. Mitteilung. Der Jodstoffwechsel des schilddrüsenlosen Hundes. *Deutsches Arch. Klin. Med.* 161(3/4): 129-142. 1 fig. 1928.—Following removal of the thyroid, the I content of the blood sinks to about half of its original value. In the thyroidectomized state the blood still contains I and the level is more susceptible to exogenous influences than in the normal animal. This was demonstrated by I metabolism experiments on 9 thyroidectomized and on 8 normal dogs.—*A. Sturm (transl. by E. M. MacKay).*

564. STURM, ALEXANDER, und BRUNO BUCHHOLZ. Beiträge zur Kenntnis des Jodstoffwechsels. V. Mitteilung. Jodverteilung im menschlichen und tierischen Organismus in ihrer Beziehung zur Schilddrüse. *Deutsches Arch. Klin. Med.* 161 (3/4): 227-247. 5 fig. 1928.—The I content of the weighed organs of 7 men, 11 dogs and 5 guinea pigs was determined. All organs examined contained I. One half to $\frac{2}{3}$ of the total body I is contained in the musculature, and $\frac{1}{3}$ to 1/10 in the thyroid. Nearly all endocrine organs have a higher I concentration than the other body tissues. The I content of a tissue is dependent on the time of year. Chronic diseases cause shifts in the tissue I. After thyroidectomy there is an extraordinary decrease in the I content of the endocrine glands but not of the body tissues in general. It is concluded that the endocrine I is dependent upon and regulated by the thyroid while the I of other tissues is practically independent of thyroid influence.—*A. Sturm (transl. by E. M. MacKay).*

565. TAKATA, RYOHEI. An undertaking on the utilization of microörganisms for human food materials. VII. Nitrogenous bases in the mycelium of Aspergillus oryzae. *Jour. Soc. Chem. Ind. Japan Suppl. Binding* 172B. 1929.—An abstract.

566. TOXOPÉUS, M. A. B. Die Verteilung des Broms im Organismus. *Arch. Exp. Path. u. Pharmakol.* 149 (5/6): 263-273. 1 fig. 1930.—NaBr, administered by mouth to 7 dogs, was found to be stored most abundantly in the muscles (37%), next in the skin (16%) and the blood (9%). This represents a very different distribution from that of normally or extranormally introduced chlorid.—*Author's summary (transl.).*

567. VICKERY, HUBERT BRADFORD, and RICHARD J. BLOCK. The basic amino acids of wool. *Jour. Biol. Chem.* 86(1): 107-111. 1930.—The basic amino acids have been isolated from the protein of sheep wool by the modified silver precipitation method. The keratin of the hair of this species yielded 0.66% of histidine, 7.8% of arginine, and 2.3% of lysine and is closely comparable to that of human hair with respect to the yields of these bases.—*Authors' summary.*

568. WAGNER, HANS. Goisern: Über Jodgehalt der Luft als klimatologisch wirksames Agens. [The I content of the air of Goisern and vicinity as a climatologic agent.] *Wiener Med. Wochenschr.* 79(34): 1084-1093. 2 maps. 1929.—Analyses of the air collected at various altitudes and in various localities in the Salzburg Alps near Goisern, Austria, were made, and the correlation of goiter incidence with I content of the air is discussed.

569. WEISER, STEFAN, und ARTHUR ZAITSCHEK. Jodstoffwechselversuch an milchenden Ziegen. *Biochem. Zeitschr.* 217(4/6): 359-364. 1930.—Two healthy lactating goats were fed a diet of KI, hay, fodder, clover, and some grain. In one 42% of the I fed was retained, 31% in the other; I excretion in the feces was 6% in one case, 3% in the other; excretion in the urine was 34% and 36% respectively; excretion in the milk 18% and 30%. A N balance determination was made at the same time as the I determination. One goat having a slightly negative N balance of 0.57 gm. showed greater I retention than a goat with a positive N balance of 0.03 gm. Control goats fed no KI in the food excreted less I in milk than those fed KI.

570. WENDT, GEORG von. Zur Biologie des Jods. Beobachtungen über die Einwirkung einer schwach jodierten Mineralsalzmischung auf die Produktion und den Gesundheitszustand der Milchtiere. *Med. Welt* 3 (41): 1490-1493. 1929.—An outbreak of calf goiter accompanied by tendency to sterility and "Umrind" of cows in eastern and central Finland in 1923 afforded opportunity to test the food value of a weakly iodized mixture of mineral salts containing a readily soluble phosphate. The plan comprised observation of milk yield, butter yield, consumption of food and physical condition of, on an average, 422 cows on 6 estates during a preliminary period of 3 yrs., a $\frac{1}{2}$ yr. transition period during which the iodized salt mixture was introduced into the diet, and finally 3 experimental yrs. The result was almost total disappearance of goiter and reduction in the incidence of "Umrind." The average annual milk production, which was 2725 liters per cow for the preliminary 3 yr. period, rose to 3120 liters per cow for the research period. The average annual butter production, which was 104.1 kgm. per cow for the preliminary 3 yr. period, rose to 120.7 kgm. per cow for the research period. The author remarks that the research should be continued over a longer period to give decisive results.

571. WILHELMJ, CHARLES M., and WALTER M. BOOTHBY. The effect of the daily administration of iodine on the calorigenic action of single intravenous injections of thyroxine. *Amer. Jour. Physiol.* 92(3): 568-573. 1 fig. 1930.—The experiments were performed on a ♀ dog on which bilateral oöphorectomy had been performed 2 yrs. previously and accustomed for 2 yrs.

to experimental procedures. A series of 13 to 15 tests was carried out each experimental day; the average results represented the day's metabolism. In 3 control experiments 10 mgm. of thyroxine were given for 190 hrs. without I; in 2 experiments I was given before and after the administration of thyroxine. The daily oral administration of I for 17 and 22 days before and for 8 days after a single intravenous injection of 10 mgm. of thyroxine did not influence the calorigenic action of thyroxine. Following the injection of thyroxine the basal heat production rose rapidly and reached its maximal height in from 22 to 70 hrs.; following this there was a progressive decrease in heat production which reached the original basal level in about 8 days. In the 3 control experiments in which I was not given the extra heat production averaged 300 calories; in 2 experiments in which I was given the average was 311 calories. The response of the same animal to repeated single injections of 10 mgm. of thyroxine was constant; the average extra heat production in 5 experiments amounted to 304 calories, and the maximal and minimal values obtained were within ± 8% of this average. The daily oral administration of I was without appreciable influence on the basal level of heat production.—*Authors' summary.*

572. **WYMAN, EDWIN T., PHILIP DRINKER, and KATHERINE H. MACKENZIE. Antirachitic value of winter sunlight in the latitude of 42° 21′ (Boston).** *Amer. Jour. Dis. Children* 39(5): 969-979. 10 fig. 1930.—Observations made during the winters of 1927-1928 and 1928-1929 on the effect of winter sunlight through Celoglass on the prevention and cure of rickets. Fifteen babies with acute rickets, in an especially constructed solarium covered with Celoglass were subjects. The infants exposed during the months of November, December, January and February became deeply tanned. Those treated after March 1, however, became tanned more quickly. In the majority of cases, beginning within 2 weeks of exposure, there was a sustained rise in the P/Ca ratio. Deposition of Ca, as shown by the roentgenograms, could be seen following exposure after the 2nd week in all cases, with calcification continuing to increase throughout the period of observation. It seems justifiable to conclude that infants and children with rickets can be cured by sunshine in Boston by exposing them during the months of November, December, January February and March to sunshine transmitted through Celoglass.—*E. T. Wyman.*

GROWTH

573. **BAHRS, ALICE M. The effect of refrigeration upon the growth-promoting power of rabbit tissues for planarian worms.** *Physiol. Zool.* 2(4): 491-494. 1 fig. 1930.—Refrigeration at −1° to 0° C. for from 1 week to 1 mo. has been found to reduce the growth-promoting power of rabbit liver, heart, and skeletal muscle when fed to planarian worms. It was also found that refrigeration at 1° to 5° C. reduced the growth-promoting power of liver more rapidly than refrigeration at −1° to 0° C. In contrast to the results upon liver, heart, and skeletal muscle, refrigeration of rabbit lung at −1° to 0° C. for from 1 week to 1 mo. was found to have practically no deleterious effect upon the growth-promoting power of this tissue.—*Author (courtesy Wistar Bibl. Serv.).*

574. **BAKWIN, HARRY, and RUTH MORRIS BAKWIN. Seasonal variation in the weight loss of newborns.** *Amer. Jour. Obstet. & Gynecol.* 18(6): 863-867. 1929.—A seasonal variation was noted in the weight loss and in the incidence of fever in newborn infants kept in a nursery at Bellevue Hospital. The infants lose considerably more during the winter than during the summer and have fever more often. No correlation was found between the weight loss during the first 4 days of life and the nursery temp., humidity, effective temp. or wet bulb depression.—*Authors' summary and conclusions.*

575. **BERG, CLARENCE P., WILLIAM C. ROSE, and CARL S. MARVEL. Tryptophane and growth. 3. 3-indolepropionic acid and 3-indolepyruvic acid as supplementing agents in diets deficient in tryptophane.** *Jour. Biol. Chem.* 85(1): 219-231. 1929.—3-Indolepropionic acid and 3-indolepyruvic acid were fed to rats upon tryptophane-deficient diets to determine whether they are capable of serving in place of the amino acid for purposes of growth. The results indicate that 3-indolepropionic acid is entirely unable to meet the requirements of the organism in place of tryptophane. But the addition to the tryptophane-deficient diet of 3-indolepyruvic acid leads to an immediate resumption of growth at a rate quite comparable to that induced by the equivalent quantity of tryptophane.—*Authors' summary.*

576. **BODINE, JOSEPH HALL. Factors influencing the rate of respiratory metabolism of a developing egg (Orthoptera).** *Physiol. Zool.* 2(4): 459-482. 14 fig. 1930.—The rates of gaseous exchange (largely O consumption) of developing eggs of grasshoppers were determined under normal and experimental temperatures, etc. Determinations were carried out on single eggs from the time of laying till hatched. Changes in the weight and water content of the eggs were also followed. Cyclic or rhythmic changes in rates of O consumption and development were found in eggs, apparently independent of environmental temperatures. Differential rates of O consumption and development at constant temperature occur during the development of eggs of *Melanoplus differentialis.* Environmental history is an important factor in determining the rate of O consumption and development.—*J. H. Bodine.*

577. **CALVERT, PHILIP P. Different rates of growth among animals with special reference to the Odonata.** *Proc. Amer. Philosoph. Soc.* 68(3): 227-274. 5 fig. 1929.—Two species of Odonata, *Nannothemis bella* and *Anax junius* were reared from egg to adult. Their growth, food supply and transformation are described and illustrated by tables and graphs. *N. bella* (3 individuals) reached the maximum larval length of 9.25-9.65 mm. in 674-1037 days (add 18 days for the embryonic period); no correlations in size, length of larval life or number of ecdyses appear. *A. junius* (1 individual) attained its maximum larval length of 44 mm. in 322-328 days (341 days from time of oviposition). Although the room temp. in which the larvae were kept was never lower than 10° C., all of them showed a halt in growth in winter. Growth in length occurs between moults in *N. bella,* in various Heteropterous, Coleopterous, Lepidopterous and Dipterous larvae and hence is continuous, as in non-Insectan Arthropods and many other Metazoa. In *Anax junius* and in most heterometabolic insects it occurs chiefly at the ecdyses and is therefore discontinuous. Temporary fluctuations in length occur in representatives of both sorts of insects as the result of ingestion and egestion. Moults are not absolute indicators of biologic age. The growth factors announced by Brooks, Dyar, Przibram and Megusar and Brody are compared and the Brooks-Przibram ratio given for each instar of the 10 species of Odonata which have thus far been reared from egg to adult. Nine of these species grew at a more rapid rate than this ratio demands. No relation between length of life and final size has been detected among the Odonata. *Anax junius,* in common with some other insect larvae, departs from the general rule that the percentile rate of growth is greatest in early age. The idea of a theoretical rate of growth may have some advantage as a standard from which to estimate the deviations of a given individual.—*P. P. Calvert.*

578. **DEMPSTER, W. T. The growth of larvae of Ambystoma maculatum under natural conditions.** *Biol. Bull. Marine Biol. Lab.* [*Woods Hole*] 58(2): 182-192. 1930.—Growth in weight of embryonic and larval *Ambystoma maculatum* from the time that eggs are deposited to the period of metamorphosis may be expressed as a single sigmoid curve. The length curve, except for a short period before hatching when the embryonic axis is curved, is likewise sigmoid. The *Ambystoma* population of a pond is quite homogeneous, the specimens metamorphosing at approximately the same time. Under

natural conditions the relation between weight and length from year to year seems to be constant during the stages before feeding. Later the relationships are variable because of feeding differences. Growth to the time of food ingestion is associated with imbibition of water. Later growth to the time of emergence of the salamanders is correlated with a process in which the percentage of water content decreases. During this period the inorganic constituents gradually increase.—*Author's summary.*

579. **ERNST, MAX. Der aseptische Gewebszerfall. Anatomische und experimentelle Untersuchungen unter Einbeziehung des Parabioseverfahrens. [Aseptic tissue-disintegration. Anatomical and experimental investigation by application of the parabiosis-method.]** *Deutsche Zeitschr. Chir.* 221(1/2): 74-92. 1929.—Normal cell breakdown, as it occurs from the instant of fertilization of the egg-cell until death, exerts no appreciable influence on the body. Investigations on over 1000 vertebrate embryos, and parabiosis experiments, gave no support to the assumption that disintegration products exert a growth-promoting influence on cells and tissues. Any increase of cell disintegration in the organism leads to abnormal flushing of protein disintegration products in the circulation, where they invoke an antigen-antibody reaction. The action on the body as a whole varies. After moderately increased cell disintegration, there are found microscopically hyalin deposits and multiplication of cells of the reticulo-endothelial system. If, however, very great quantities of these products suddenly enter the body, death follows promptly. Microscopically no changes are found, as the time is too short for their development. Death of a parabiotic animal results from protein disintegration products arising from normal cell breakdown of the paired animal; these lead to slowly progressive poisoning.—*M. Ernst (transl. by W. Browning).*

580. **GRAY, J. The kinetics of growth.** *British Jour. Exp. Biol.* 6(3): 248-274. 7 fig. 1929.—After discussing the validity of growth formulae, the author deals with the laws of unorganized growth as exemplified by unicellular organisms (e.g., cultures of bacteria and of yeast). As long as the external environment is maintained at a satisfactory and constant level, each cell of a homogeneous population multiplies at a rate which is constant within definable limits; there is no indication that the powers of growth are declining with the age of the culture. The essential features exhibited by a growing culture of bacteria are also seen in metazoon cells grown *in vitro,* although the requisite conditions for growth are more specific, one of these being the concentration of embryonic extract present in the medium. In the growth of a metazoon body the conditions are extremely complex. It is difficult to express the growth rate of the whole organism in terms of rational units, since the units which compose the body form a very heterogeneous system in which the rate of growth of one organ is dependent on that of others. It is therefore improbable that the behavior of such a system should conform to that of a simple chemical system.—*F. A. E. Crew.*

581. **HAMMETT, FREDERICK S., and DOROTHY WALL SMITH. The influence of sulfhydryl and sulfoxide on gross regeneration in the hermit crab (Pagurus longicarpus).** *Protoplasma* 13: 261-267. 1931.—The right front claw of hermit crabs was removed and thereafter allowed to regenerate in cultures of pure fresh sea-water, sea-water plus *p*-thiocresol, cresol, di-phenyl sulfoxide, and sodium benzene sulfonate. The sulfhydryl group accelerated regeneration and differentiation as compared with the growth taking place in the control cultures containing sea-water alone, or sea-water plus an equivalent amount of cresol. Sulfoxide retarded regeneration and differentiation as compared with the growth occurring in sea-water and in sea-water plus sulfonate controls. It is concluded that the chemical equilibrium regulative of growth by increase in cell number is a determinant of regeneration rate as it is in all other types of cell multiplication so far studied.—*F. S. Hammett.*

582. **HAMMETT, FREDERICK S. The proliferative reaction of the skin to sulfhydryl and its biological significance.** *Protoplasma* 13: 331-347. 1931.—The midscapular region of mice was rubbed with benzyl mercaptan in mineral oil and in alcohol. This surface application of the sulfhydryl group caused a marked proliferation of the epithelium and of the connective tissue of the corium. This resulted in an enhancement of differentiation so that the skin of the mouse took on a complexity of structure analogous to that of the higher animal man. In some cases the proliferation of epithelium predominated, in others the connective tissue. These differences are obviously constitutionally determined and have their analogs in humans, some of whom develop epithelial overgrowths or carcinomas while others develop connective tissue malignancies or sarcomas. In cases where the sulfhydryl action was accompanied by alcohol irritation there occurred overgrowths, both upwards and downwards.—*F. S. Hammett.*

583. **KOTSOVSKY, D. La signification du sommeil et de la croissance pour la biologie de la vieillesse.** *Riv. Biologia [Milano]* II(3/4): 360-364. 1929.—The author presents 3 series of observations during 6 mo. on the growth and the duration of sleep of 5 dogs from the same litter and believes that there is a definite relation between the processes of growth and sleep. He believes that the higher centers of psychic activity are responsible for the onset of old age and not the various endocrine glands.—*D. Kotsovsky (transl. by S. Thayer).*

584. **KRONTOWSKI, A. A. Quantitative Untersuchungen über die Wirkung des Diphtherietoxins auf das Wachstum und den Stoffwechsel der Gewebskulturen.** *Zentralbl. Bakt. Abt. I. Orig.* 117(6): 328-343. 7 fig. 1930.—Each of 2 cultures of chick embryo heart were divided and ½ of each placed in a medium containing diphtheria toxin (1: 100,000 and 1: 1,000,000 respectively) while the other ½ of each was placed on ordinary medium as a control. Measurements of growth showed a distinct inhibitory effect exercised by the toxin. Tissues grown in a lower (solid) layer of medium in 6 Carrel flasks had diphtheria toxin in the same dilutions introduced in the upper (fluid) layer in 4 of the flasks; a similar quantitative inhibition of growth was observed in the 4 flasks containing toxin. A culture the growth of which had been completely stopped by the 4-day action of diphtheria toxin was restored, by repeated passage to normal media, to a growth equal to that of the control, showing that the injury inflicted by diphtheria toxin is reversible. The metabolism of the toxin-treated cultures showed marked inhibition of sugar consumption and lactic acid formation as compared with normal metabolism.—*Based on author's summary (transl.).*

585. **LEUPOLD, ERNST. Der Einfluss des örtlichen Stoffwechsels auf die reaktiven Vorgänge bei der Wundheilung und Regeneration.** *Beitr. Path. Anat. u. Allg. Path.* 81(1): 45-100. 11 fig. 1928.—A small wound was made in the skin of the white mouse between the shoulder blades. Inorganic and organic substances concerned in metabolism were injected in the neighborhood of the wound, to study the question of relationship between the cellular reaction in regenerative processes of wound repair and local metabolic changes. These were demonstrated. The inorganic salts, especially the ions, act as a stimuli which produce growth. Among the cations the Na ion is especially active; with the anions, it is important whether there is a strong or a weak acidity. A typical growth of epithelial cells appears at a p_H of 8 to 10. There is an increase in connective tissue proliferation in anisoionic and anisotonic solutions. Proteins, glycogen and dextrose apparently are effective only in connection with acids. During regeneration and following the injection of fatty tissues, there are growths of glands resembling lactating breast tissue. From the endothelium of the tissue spaces there are structures developed resembling endotheliomata or

cylindromata. These also develop as the result of changed metabolism.—*E. Leupold (transl. by R. H. Major)*.

587. NYLIN, GUSTAV. Periodical variations in growth, standard metabolism and oxygen capacity of the blood in children. *Acta Med. Scandinavian Suppl.* 31: 1-207. 1929.—The author has investigated the growth of 809 children from Spånga elementary schools and 1,094 children from elementary schools in Spånga and Stockholm during the months of January, March, May, September, November and again in January. The children were measured and weighed totally stripped. For the purpose a special measuring apparatus was constructed. The error of measurement was calculated statistically by repeated determinations on the same individual in a group of children; this was found in an individual measurement to be ± 1.7 mm. Each child was measured at almost exactly the same hour and by the same examiner. The height varies during different times of the day. Measured during the first 4 hrs. after rising in the morning the height diminishes by 2 mm. during the 1st hour, 4 mm. during the 2nd and by 1 mm. during the 3rd hour; during the 4th hour no diminution was in evidence. Simultaneously with measuring the height of the children their weights were taken. On 8 quite healthy and normally developed children at the age of 6 years, standard metabolism tests were carried out every day at 8 o'clock in the morning during the months of July, September, November, January, March, May and July on an empty stomach. The O consumption was determined during 15 min. by a Krogh's respirometer, the results of the last 10 min. only being used for calculations. During the test period each child was measured and tested for height, weight, hemoglobin, temperature and pulse frequency. Two groups of boys were selected with body heights of 120-140 cm. and irradiated every other day by means of 2 Jesionek lamps and 4 Soolux lamps. The first group comprised 23 boys, irradiated from November 11 till January 20 inclusive, and the second group, 22 boys, irradiated January 23–March 20 inclusive. In total each group was irradiated about 7 hours. Heights and weights were taken of all the children on 3 occasions, in November, January and March. This was done on exactly the same minute on all occasions and for each child 3 readings of the body height were taken on each occasion. The investigations show that during a calendar year there is a marked periodicity in increase of both height and weight, which presents similarities, (a) within various age-groups, (b) for elementary school children, both boys and girls, (c) for both the investigation years 1926-1927 and 1928-1929, both in Stockholm and at Spånga. As a rule, height-increases show one minimum in September-November and another in January-March, one maximum in March-May and another in November-January. During the summer, height-increase is somewhat pronounced. Weight-increase shows two minima coincident with the two maxima in height-increase, and two maxima coincident with the two minima in height-increase. Weight-increase is slight from May-August, rising gradually during the following months to a maximum in September-November, as mentioned above. Weight-increase was more strongly marked during the summer of 1928 than during the summer of the previous year. Reckoned in periods of 4 mos., thus January-May, May-September, and September-January, it is shown that height-increase is greatest during the first 4 mos. of the year, decreases during the next period of 4 mos.—the intermediate period—to decrease further to a minimum during the last 4 mos. of the year. Apart from this exogenous periodicity in both height-increase and weight-increase which thus generally appears in certain fixed months of the year, there is an endogenous periodicity in that a great increase in height or weight in one period is always followed by a slight increase in height or weight in the following period, as is indicated by the fact that the correlation coefficient between the increase in the successive periods is negative. The experimental investigation as to the influence of light on growth showed that light baths stimulate height-increase during the period when irradiation is being given, but retard the weight-increase. In the case of the 8 pre-school children, standard metabolism shows a periodicity during the year, intimately connected with height-increase, so that during the maxima in height-increases, particularly during November-January, there is a maximum in standard metabolism. The somewhat great height-increase during March-May is not followed by an increase in standard metabolism, but this follows later, i.e., during May-July, during which period height-increase is also strongly marked. During both the minimum periods of height-increase, namely September-November and January-March, standard metabolism shows a minimum. The O capacity of the blood shows a variation during the year, so that a minimum presents itself in the 8 preschool children in January. From January it increases during the following mos. to a maximum at the end of May. In the case of 6 school children, the O capacity of the blood shows a similar variation during the year, in that a minimum appears in February, increasing successively during the following mos. to a maximum in August.—*G. Nylin.*

588. PARKES, A. S. Note on the growth of young mice suckled by rats. *Ann. Appl. Biol.* 16(1): 171-173. 1929.—"Normal growth in mice is inversely proportional to the number suckling the mother. When receiving unlimited food (when suckling a rat) the growth is so rapid that the bones cannot support the body."—*R. E. Stanton.*

589. REITER, HANS. Untersuchungen über elektive Ernährung und Wachstum. *Med. Klin.* 25(7): 267-269. 1929.—In rat experiments the author shows that by addition of liver (Hepatopson) prepared by drying in a vacuum, or testicle substance prepared in a like manner, to a control diet deficient in vitamin A, marked improvement in growth took place. Testicle substance was effective only in males. Addition of 2 gm. of Hepatopson quickly cured the eye disease and produced a gain in weight.—*R. G. Turner.*

590. ROBB, R. CUMMING. On the nature of hereditary size limitations. I. Body growth in giant and pigmy rabbits. *British Jour. Exp. Biol.* 6(3): 293-310. 6 fig. 1929.—The Flemish is the largest, the Polish the smallest, breed of rabbits. At birth the former are twice as large as the latter. This cannot be explained by differences in length of gestation (31 and 30 days respectively) and it may be assumed that a factor (or factors) exists which depresses the rate of growth of the small race, or accelerates that of the large. The specific growth rate from birth to onset of puberty is identical in the 2 breeds, but at 4 mos. the Polish and hybrids show a retardation of growth. The lesser size of the Polish can be ascribed to the action of 2 factors, one operating in utero, the other at a more advanced age. Flemish × Polish hybrids (either way) are at birth almost as large as purebred Flemish; in their adult size they are intermediate. But their growth curve does not lie midway between those of the parents. Prior to its inflection at the 4th mo. of post-natal life it is similar in magnitude to that of the Flemish; thereafter the rapid retardation resembles that of the Polish. Further, the values of the 2 velocity constants in the hybrids are not both intermediate, one of them being practically identical with the value of the Polish. This would indicate a segregation of unit characters. There occur 2 deviations of observed values from the theoretical, the 1st associated with birth, the 2nd with an endocrine reorganization involving thymus, testes, and adrenal cortex. These 2 retardations divide the growth curves into 3 cycles. In the light of this observa-

tion, the assumption of autocatalyzed master reactions is superfluous.—*F. A. E. Crew.*

591. ROBB, R. CUMMING. On the nature of hereditary size limitation. II. The growth of parts in relation to the whole. *British Jour. Exp. Biol.* 6(4): 311-324. 1929.—The relative weights of pituitary, thyroid, thymus and adrenals in the rabbit throughout post-natal life may be expressed by the equation $y=ax^k+c$. In giant and pigmy rabbits, the ultimate proportions of body parts are not the same, but at any given body weight corresponding tissues in the 2 groups tend to exhibit an identical relation to total body mass. The adrenals and testes of Polish rabbits are relatively much larger than those of Flemish. But in each case the growth of the adrenal approximates to a constant power function of body weight. Moreover, in these 2 groups and in their hybrids, the growth of the testes adheres to a simple association with adrenal weight which is identical for each. These data suggest that in a growing organism the magnitude of any part tends to be a specific function of the total body mass or of some portion so related to the whole. These correlations may be explained by surmising that each tissue is in equilibrium with the internal milieu with regard to the distribution of nutrient growth essentials; that in each case the equilibrium point would tend to remain constant; and that the relative enlargement of each tissue is limited by the excess of the equilibrium value over the katabolic expenditure. According to the above hypothesis of organ growth, the equation $y=ax^k+c$ may possess a physical significance. Eight types of growth relationships may thus exist, differing because of the apparent inactivity of one or more constants in this equation.—*Author's summary.*

592. ROMANOFF, ALEXIS L., and ANASTASIA J. ROMANOFF. Changes in pH of albumen and yolk in the course of embryonic development under natural and artificial incubation. *Biol. Bull. Marine Biol. Lab.* 57 (5): 300-306. 3 fig. 1929.—In the course of embryonic development the pH values of albumen of the hen's egg rapidly change towards alkalinity and back during the 1st week of incubation, reaching the highest point of alkalinity at about 48 hrs. For the rest of the incubation period it gradually moves towards neutrality. The pH of egg yolk gradually changes throughout the incubation period from acid to alkaline, with a sudden temporary drop at the 16th day.—*Authors' summary.*

593. SCHLEISSNER, FELIX. Somatogramme. [Body growth.] *Monatsschr. Kinderheilk.* 43(5): 484-493. 1929.—This is a method for the graphic representation of the height-weight ratio at different age levels. As a basis for the graph, the von Pirquet tables of growth are used, the figures for age, weight, and height being placed in parallel, vertical columns. The figures for an individual are then connected by straight lines, and the resulting curves for the different age levels often show a remarkable parallelism. By this means it can be shown that the curves plotted from children of the poorer classes (as for example, those in orphan homes) fall considerably below the average, whereas those from patients in private practice are above. It seems quite possible that a definite prediction as to ultimate growth in body length can be made even as early as 2 years of age, provided the child's growth has not been influenced by illness or endocrine disturbance.—*T. C. Hempelmann.*

594. SCHMALHAUSEN, I. Die Bestimmung des spezifischen Wachstumsertrages als vergleichende Untersuchungsmethode. [Determination of specific growth rate.] *Zeitschr. Wiss. Biol. Abt. D. Roux' Arch. Entwicklungsmech. Organ.* 115(4/5): 678-692. 1 fig. 1929.—By specific growth rate is meant the total increase during a certain period of time or during the whole period of growth. The value of the specific growth rate is independent of the size of the initial mass of an organism. Within each growth period the specific growth rate of an organism appears as a simple logarithmic function of time and can very easily be calculated according to the following formula: $u=k\ln(t^2/t^1)$ where k indicates the size of the growth constant. In different vertebrates the specific growth rate has approximately the same value, becoming as high as 20 or 25 in the larger animals while in the smaller animals it appears to be only about half that. The initial and final size of an organism stand in a simple relation to the specific growth rate which is expressed very exactly for any desired period of time by the following formula: $v=mc^k$. The final size appears therefore as an exponential function of the specific growth rate and is directly proportional to the initial mass.—*Author's summary (transl. by J. L. Lush).*

595. SMITH, ARTHUR H., and WILLIAM E. ANDERSON. Lactation vs. improved growth in stock albino rats. *Science* 70(1804): 98-99. 1929.—Beginning rather uniformly in the 5th generation, failure in lactation was observed in rats given a ration consisting of whole ground wheat 2/3, dried whole milk 1/3, $CaCO_3$ and NaCl each 1% of the weight of the wheat, lettuce and dried yeast. This diet is satisfactory for growth after weaning.—*A. H. Smith.*

596. STEFKO, W. H. Zur Lehre über den dystrophischen Infantilismus. *Zeitschr. Ges. Anat. Abt. II. Zeitschr. Konstitutionsl.* 14(5): 610-624. 8 fig. 1929.—By "dystrophic infantilism" the author means delayed puberty associated with retarded growth and poor physical development. It is found most frequently in those Russian provinces where famine was most widespread. In 1927 it was observed in about 25% of 2300 young people between 14 and 17 years old; at the time of writing the proportion was 8 to 14%. Anthropometric data are tabulated for 20 infantile dystrophies; the histologic findings in the sexual and endocrine glands in 2 necropsies are reported on persons 19 and 21 years old respectively. No mature spermatozoa were present. Hypoplasia of the thyroid and medullary tissue of the suprarenals was characteristic. According to Stefko's view, dystrophic infantilism is the result of unfavorable and insufficient nutrition acting on a congenitally deficient constitution of the sexual glands; the sexual inferiority, however, might never have become apparent if not brought to light by the unfavorable external conditions.

597. VIVARIO, R., et J. LECLOUX. Sur la formation de "glutathion" au cours de la croissance. *Arch. Internat. Physiol.* 32(1): 1-14. 1930.—Previous researches of other authors have shown that in the fertilized hen's egg glutathione is at its maximum while the cells are multiplying without differentiation. The object of the present research was to trace the origin of glutathione, which might ultimately throw some light on cancer metabolism. No glutathione was discovered in dry peas; hydration of the peas induced formation of glutathione, which in about 4-6 hrs. reached a level that was maintained to the end of the experiments (48 hrs.); heat (38°) hastened its formation. The process went on more rapidly and a greater quantity of glutathione was found if pea flour rather than whole peas was used, apparently because the water was more quickly absorbed. The authors conclude that the formation of glutathione, under the influence of the penetration of water into the seed, is one of the factors of germination.

598. ZABINSKI, J. The growth of blackbeetles and of cockroaches on artificial and on incomplete diets. I. *British Jour. Exp. Biol.* 6(4): 360-386. 1 pl. 10 fig. 1929.—The normal development of blackbeetle lasts about 12 mos., that of the cockroach about 12 weeks. The animals were given different diets to examine the effect of variation of nitrogenous matter in different forms upon growth. Three diets were used which varied in their N-constituents, while the N-content of all was identical. All diets were avitaminosed by heating. On a diet containing 15% glycocoll or one containing 20% gelatine, the animals grew normally for a period equalling ⅓ to ½ of the total post-embryonic cycle, after which there began a progressive retardation of growth. The maximum weight was never more than ⅓ the normal. Animals exhibited typical signs of avitaminosis. On a diet containing 18% ovalbumin, initial growth was as rapid. But death followed abruptly before the end of the 4th moult and there were no signs of avitaminosis. Addi-

tion of vitamine B to the above diets gave negative results. Next animals were fed on diets with varying N-content. A diet deficient in N was found to cause a marked retardation of growth, the growth curve showing a slow increase without the abrupt rise and fall as found above. Diets containing protein alone caused death within a short time, without previous increase in weight. A diet containing ammonium sulphate as the sole source of N led to death within 7-10 days. When fed on an exclusively carbohydrate diet, the animals exhibited great resistance and arrested growth. A change to a diet containing N led to a resumption of normal growth, even after a prolonged arrest.—*F. A. E. Crew.*

VITAMINES

599. **ASKEW, F. A., R. B. BOURDILLON, H. M. BRUCE, R. G. C. JENKINS, and T. A. WEBSTER. The distillation of vitamin D.** *Proc. Roy. Soc.* [*London*] *B* 107(748): 76-90. 5 fig. 1930.—A method is described for the partial separation of the irradiation products of ergosterol, by distillation and fractional condensation in a high vacuum. By double distillation, followed by crystallisation from aqueous alcohol, a crystalline product has been obtained, showing high antirachitic power, and a melting point of 113° to 115° C. It is not suggested that these crystals are pure vitamin D. They may consist of an inactive substance contaminated with an extremely active vitamin, or of crystalline vitamin forming mixed crystals with an inactive substance. It is possible, on the other hand, that several antirachitic substances are formed by the irradiation of ergosterol, and that the crystals are a relatively pure specimen of one of these substances. Some evidence is given as to the degree of efficiency of the process of fractional condensation in a high vacuum.—*Authors' summary.*

600. **ASKEW, F. A., R. B. BOURDILLON, H. M. BRUCE, R. G. C. JENKINS, and T. A. WEBSTER. The effects of further irradiation of the radiation products of ergosterol.** *Proc. Roy. Soc.* [*London*] *B* 107(748): 91-100. 3 fig. 1930.—Resins prepared by the irradiation of ergosterol and the subsequent removal of the unchanged ergosterol show absorption maxima near 280mμ. This maximum was previously ascribed to vitamin D. Resins prepared by irradiation with light of wavelength greater than 280 mμ have this maximum considerably increased when re-irradiated with shorter waves only. This increase in absorption is accompanied by a fall in antirachitic activity, thus showing that the substance responsible for the absorption at 280 mμ is not vitamin D. Some of the constituents of these resins have been partially separated: one of these is characterised by its extremely rapid destruction by light of wavelengths shorter than 280 mμ.—*F. A. Askew.*

601. **BATCHELDER, ESTHER LORD. The effect of successive diminutions of vitamin A in the food on the nutrition and vitality of albino rats.** 33p. Dissertation, Columbia Univ.; New York City, 1929.—Systematically graded intakes of vitamin A in the form of whole milk powder were fed to standardized albino rats during 8 weeks. The growth responses were compared with results of other investigations and were used in interpreting measurements of vitamin A in other food materials. Comparable lots of rats were fed vitamin A in the form of butter fat in doses of 0.5, 1.0, 2.0, 4.0, and 8.0% by weight of food ingested, the rest of the diets consisting of whole wheat, skimmed milk powder, table salt and Crisco to make a total of 8% fat. Rate of growth, body weight, reproduction, lactation, longevity, and the vigor of succeeding generations were used in judging the adequacy of the diets. The data illustrate the advantage of coordination of a series of criteria, rather than dependence on any one criterion, in the formation of a comprehensive judgment of nutritional need for and significance of vitamin A.—*E. L. Batchelder.*

602. **BAUER, WALTER, and ALEXANDER MARBLE. Preliminary note on the mode of action of irradiated ergosterol.** *New England Jour. Med.* 201(17): 809-911. 1929.—This was a study of the effect of irradiated ergosterol on the relative rate of restoration of bone trabeculae in the humerus of cats on high Ca diets, the trabeculae having been depleted by a previous low Ca diet free from vitamin D. The much greater increase in the number of trabeculae when irradiated ergosterol was administered is interpreted as indicating increased absorption of Ca from the gastrointestinal tract.—*L. S. Palmer.*

603. **BLUNT, KATHERINE, and RUTH COWAN, (foreword by MORRIS FISHBEIN). Ultraviolet light and vitamin D in nutrition.** 229p. 39 fig. Univ. Chicago Press: Chicago, 1930. Pr. $2.50.—The authors have culled the vitamin D literature for the most authoritative papers, including both laboratory and clinical investigations. They discuss problems of growth as related to skeletal development and review much of the work on Ca and P metabolism, particularly in relation to rickets. No definite conclusions are drawn from the literature. The book is a concise review of the subject for teachers of nutrition, clinicians and laboratory workers.—*R. G. Daggs.*

604. **BOURDILLON, R. B., R. G. C. JENKINS, and T. A. WEBSTER. The absorption spectrum of vitamin D.** *Nature* [*London*] 125(3156): 635. 1930.—Further study has demonstrated the incorrectness of the authors' view (in *Proc. Roy. Soc. B.* 104: 561. 1929. See *B. A.* 4(3): Entry 7658) that the substance in ergosterol, responsible for the high absorption at 280 mμ, is vitamin D. By use of light screens, and by irradiating ergosterol with light of λ greater than 280 mμ, then with that of 280 mμ or less, preparations (1) of high antirachitic potency and low absorptive power (as to light of 280 mμ) and (2) of low antirachitic potency and high absorptive power, were obtained. The intense maximum of absorption at 280 mμ in early stages of irradiation is not due to vitamin D. This agrees with the findings of Reerink and Van Wijk (*Biochem. Jour.* 23: 1294. 1924) and Windaus (*Nachr. Ges. Wiss. Göttingen,* 36-57. 1930).

605. **BROOKS, F. P., ROY F. ABERNETHY, and F. C. VILBRANDT. Preliminary study on the antirachitic properties of shrimp oil.** *Jour. Amer. Chem. Soc.* 52(12): 4940-4943. 1930.—It was found from the analysis of the blood and the bones that shrimp oil has properties akin to cod liver oil, tending to cure the rachitic rats. In the 1st series shrimp oil was as potent as cod liver oil. The 2nd series showed some curative action but less than with cod liver oil, probably due to increasing rancidity of the shrimp oil.—*Authors' summary.*

606. **CASTILLE, et E. RUPPOL. Sur l'activation photochimique de l'ergostérol.** *Bull. Acad. Roy. Méd. Belgique* 9(11): 799-821. 3 fig. 1929.—The ultraviolet absorption was measured by the method of V. Henri. The strong band (2600-3000 Å) is probably due to the ethylene linkages. The spectrum of ergosterol and of its acetate indicates that in the normal state it contains 3 ethylene linkages in conjugated positions united to a benzene ring. The alcoholic groups are close to the benzene ring. The irradiated specimen shows that ethlyene linkages are not joined to the benzene ring. Ergosterol in hexane and alcohol on irradiation undergoes an isomerization, in ether it undergoes isomerization plus oxidation, while in chloroform it undergoes isomerization plus chlorination.—*H. Kahler.*

607. **CHAKRABARTI, SACHINDRA NATH. Investigation on the products obtained by exposing oils and carbohydrates to sunlight in presence of air.** *Allahabad Univ. Studies* (*Sci. Sect.*) 6(2): 227-238. 1930.—It has been shown that if olive, mustard, cocoanut, mahua, castor, til, and linseed oils, butter and some carbohydrates are exposed to sunlight, and air is passed through them, peroxides are formed. These peroxides have been estimated by the amount of I liberated by them from an acid solution of KI. If the oils are only exposed to sunlight and air is not passed through them, the amount of peroxide formed is greatly decreased, due to the smaller amount of air which comes in contact with the oil surface. All these oil-peroxides have the property of oxidizing solutions of glucose when mixed

with them and kept at 40° C. for 18 hrs. The amount of this oxidation is dependent upon the availability of O from the peroxide. From experiments on pigeons with exposed and unexposed oils, Fe and sunlight, we have proved that sunlight is the best preventive for diseases like polyneuritis and beri-beri. Olive oil exposed to sunlight and air comes a close second, whereas Fe and unexposed oils are harmful to these pigeons.—*Author's summary.*

608. **COCCHERI, PIETRO. Influenza della ergosterina irradiata e delle vitamine idrosolubili sullo sviluppo delle larve di Bufo vulgaris. [Action of irradiated ergosterol and of water-soluble vitamins on development of larvae of B. vulgaris.]** *Biochim. e Terapia Sperim.* 17 (9): 372-378. 1 fig. 1930.—Overdoses of irradiated ergosterol were toxic; but were counteracted by administration of water-soluble vitamins.—*M. Comel.*

621. **GUNDERSON, F. L. Vitamin D and the antirachitic activation of foods by irradiation with ultraviolet light.** *Cereal Chem.* 7(5): 449-455. 3 fig. 1930.—A review with bibliography.

622. **HOYLE, JOHN CLIFFORD, and HARRY BUCKLAND. Further observations on the effects of large doses of irradiated ergosterol.** *Biochem. Jour.* 23(3): 558-565. 3 fig. 1929.—Half grown rats weighing 180 gm. consumed an average of 26.4 mgm. of irradiated ergosterol per animal per day for 45 days. This ergosterol was irradiated in an oily solution, and samples irradiated under similar conditions showed a potency of 1600 units per mgm. The effects of this overdosage of irradiated ergosterol were: an immediate loss of about

10% in weight after which they continued at about the same level, and an increase in the volume of urine excreted by 200-300%. Total urinary phosphate and chloride were not affected. The pH of the urine was not changed significantly, being only slightly higher in the experimental group. All the animals survived the experimental period and were then killed. Postmortem findings were: calcium phosphate calculi in the kidney, ureters or bladder of 9 of the 12 experimental animals, and some arteriosclerosis of the aorta in 4 of them.—*R. F. Light.*

623. **HUME, E. M., and I. SMEDLEY-MACLEAN. Some further notes on the relation of carotene to vitamin A.** *Lancet* 218(5554): 290-292. 1930.—The presence or absence of fat from the food of rats, on a diet devoid of vitamin A was not found to be a factor of importance in determining the biological activity of carotene as a source of vitamin A. The use of ethyl oleate as a solvent for carotene is most unsuitable, since the dissolved carotene is rapidly oxidised in it. This solvent has been used by workers who have reported that carotene is inactive as a source of vitamin A and its use would appear to be a sufficient explanation of their finding.—*E. M. Hume.*

624. **HUME, E. M., and H. HENDERSON SMITH. The value of foodstuffs for vitamin A.** *Lancet* 2(5599): 1362-1363. 1930.—In efforts to determine the minimal dose of carotene required to maintain life without promoting growth 2 rats were maintained for 28 days on 20 mgm. and 30 mgm., respectively, daily, of fresh spinach. The 20 mgm. was estimated (by Arnaud's figures) to contain about 0.003 mgm. of carotene. Minimal doses were, for: spinach, 20 mgm. or less; cabbage, more than 20 but less than 80 mgm.; butter, 28 mgm. or less. The number of experimental animals used was too small to be conclusive, but the authors believe that with 3 or 4 animals a difference of 50% in doses can be detected. They suggest that a "biological technique based on maintenance of the rat rather than growth" can be used with fewer animals. Carotene might be used as a standard after determining the chemical and physical constants to be required of the standard carotene.

625. **IRWIN, MARGARET HOUSE, A. E. BRANDT, and P. MABEL NELSON. Applications of statistical method to the data of vitamin feeding experiments.** *Jour. Biol. Chem.* 88(2): 449-470. 1930.—1. The percent effect of measured variables. A statistical study of the data of 929 vitamin A and B feeding tests was made with a view to determining the factors responsible for the variations in the weight gains of the rats used. A comparison of the mean initial weights, days to depletion, final weights, and gains, of rats fed different basal diets free of vitamin A is reported. A similar comparison is given for rats fed different diets free of vitamin B. Correlations between the factors initial weight, total food intake, and gain in weight are given for both vitamin A and B test animals. The percent effect of the measured variables upon the gain in weight was calculated from the partial regression coefficients. The total basal diet ingested was found to be the factor having the greatest influence upon the growth response. 2. How many animals per experimental lot? The factors, initial weight, days on experiment, and total basal diet ingested, were used as the independent variables and total gain as the dependent variable in calculating multiple correlation coefficients and regression equations for 349 vitamin A test rats and 330 vitamin B test rats. Using the standard error of estimate to represent the variability of the animals and the criterion $MD/\sigma_{MD}=3$ as indicative of significance, an estimate of the mean difference in weight gains and number of animals per experimental lot necessary to obtain results of statistical significance in vitamin testing was calculated. Tables of the mean differences and the number of animals per lot to be used in routine vitamin A and B testing in the Iowa State College laboratory are given.—*M. H. Irwin.*

626. **JONES, D. BREESE, J. C. MURPHY, and E. M. NELSON. Biological values of certain types of sea food. II. Vitamins in oysters (Ostrea virginica).** *Indus. & Eng. Chem.* 20(2): 205-210. 1928.—Fresh Chesapeake oysters were ground in a frozen condition to a homogeneous consistency, and preserved in this state throughout the period of experimentation. Experiments with albino rats showed that oysters are a good source of vitamins A, B, and D. Two grams (0.32 gm. on a dry basis) of oysters furnished sufficient vitamin A to cure rats of xerophthalmia. Tests made by the curative method showed that 3.5 gm. (0.56 gm. dry basis) of oysters contained nearly enough vitamin B to supply the needs of young rats. For long-continued normal growth, however, a little more than 5 gm. (0.8 gm. dry basis) was required. Five grams of oysters given to rachitic rats daily for 10 days induced slight calcification of the long bones, comparable in degree with that produced in the same length of time by 4 mgm. of good cod-liver oil. The same daily quantity of oysters induced about half calcification in 15 days and complete calcification of the rachitic metaphyses in 20 days. Oysters were found deficient in the factor required for reproduction and rearing of young. Dehydration at 40° C. under reduced pressure (10 to 15 mm.) was found to inactivate to a great extent vitamins A and B in oysters. —(*Courtesy Industrial & Engineering Chemistry.*)

627. **JONES, D. BREESE, E. M. NELSON, and J. C. MURPHY (with the cooperation of J. P. DEVINE). Biological values of certain types of sea foods. III. Vitamins in clams.** *Indust. & Eng. Chem.* 20(6): 648-652. 1928.—Feeding experiments with albino rats showed that clams are a good source of vitamins A and D. Two species of clams were used, *Venus mercenaria,* commonly known as "hard-shell clams" or "quahaugs," and *Mya arenaria,* commonly called "soft-shell clams." Both species contain little, if any, vitamin B. Soft-shell clams were found to be a somewhat better source of vitamin A. No difference was observed with respect to vitamin D. Five grams daily of soft-shell clams, equivalent to 1 gm. of dry material, are sufficient for the cure and prevention of xerophthalmia. Somewhat more of hard-shell clams is required. Five grams of either species given daily to rachitic rats induced complete calcification in the small bones in 15 days. The rate of calcification was not appreciably influenced by the ash constituents of the clam. Compared with oysters, which are rich in vitamin B, clams are practically devoid of this vitamin. As a source of vitamin A clams are somewhat inferior to oysters, but they have more vitamin D, and are a better source of the factor, or factors, essential for reproduction and rearing of young.—(*Courtesy Industrial & Engineering Chemistry.*)

628. **KAWAI, K. Pharmakognostische Studien über den Lebertran des Japanischen Dorsches ("Tara"). [Pharmacognostic studies of the liver oil of the Japanese haddock.]** *Jour. Pharmaceut. Soc. Japan* 49(7): Japanese orig., 708-729; German summary, 108-109. 1929. —In the present Japanese Pharmacopoeia (Pharm. Jap. IV), *Gadus macrocephalus* Tilesius and *Pollachius Brandti* Jordan & Snyder are specified as sources of liver oil. In comparison with the former, an oil prepared from the livers of the "Sukesodara" or "Suketo" (scientific name in doubt) is by far the stronger. There are great differences in the vitamin A content of the oil, depending on the time of the year of the catch. The oil from male or female fish at the time of breeding is most efficient, the livers at that time showing the smallest amount of oil. The rat-growth method and the colorimetric test for vitamin A agreed well with each other.—*Author's summary (transl. by C. C. Plitt).*

629. **KOHMAN, E. F., W. H. EDDY, and NELLIE HALLIDAY. Vitamins in canned foods. VI. Strawberries.** *Indust. & Eng. Chem.* 20(2): 202-204. 1928.—Strawberries are a rich source of vitamin C, similar to tomatoes in this respect. The daily feeding required for protection against scurvy and normal growth of the guinea pig is between 2 and 3 gm. Commercially canned

strawberries considerably over a year after canning have a vitamin C content similar to that of raw strawberries. Since strawberries contain considerable O, it is indicated that the exhaust plays an important part in making it possible to can them with no apparent loss in vitamin C. Strawberries are not highly endowed with vitamin A, being only 1/40 as rich in it as tomatoes. Strawberries are about ¼ as rich in vitamin B as tomatoes.—*Authors' conclusions.*

630. **KOHMAN, E. F., W. H. EDDY, and CELIA ZALL. Vitamins in canned foods. IX. Tomato products.** *Indust. & Eng. Chem.* 22(9): 1015-1017. 1930.—A review of previous work upon the vitamin content of tomatoes shows that the results vary largely with the methods of treatment. This study contrasts the vitamin content of whole tomatoes canned by the usual commercial process with that of tomato pulp and juice, prepared by methods analogous to those in trade use. Vitamin A retained its potency after concentration under vacuum for periods of 20 min., 2½ hrs., or 4 hrs., and after heating in open vessels, but filtration with celite to remove the pulp destroyed this vitamin. Vitamin B was likewise destroyed by this filtration; heating to 155° F. in open buckets also destroyed it. Vitamin C was destroyed partially or completely by beating air into the juice as in the commercial preparation of tomato pulp. The high antiscorbutic potency of the canned whole tomatoes was in contrast to the other preparations. If the material was heated while air was bubbled in, destruction of Vitamin C did not take place, suggesting that steam acts as a protective envelope.—*M. Fay.*

631. **KOLLATH, WERNER. Biologische Bedeutung wasserlöslicher, pflanzlicher Phosphatide; ihre Wirkung auf das Wachstum von Bakterien und höheren Organismen und ihre Beziehungen zum Vitaminproblem.** *Jahresber. 101, Schlesisch. Ges. Vaterländ. Cultur. Med. Sekt.* Pt. 2. 1928: 42-52. 1929; also in *Med. Klinik* 24 (20): 778-781. 1928.—Water-soluble plant phosphatides obtained by extracting sterilized plant substances hastened the appearance of certain growth forms in diphtheria bacillae. These phosphatides may also be necessary for the formation of "Riesenwachstum" by influenza bacillae. In pigeons on a deficient diet resulting in beriberi, the administration of these phosphatide extracts greatly extended the time before the appearance of the symptoms although these were not prevented. In mice the extracts appeared to increase the storage of fat and P and acted as a growth promoting substance.—*C. M. Conrad.*

633. **McCARRISON, R. The influence of irrigation on the nutritive value of rice.** *Indian Jour. Med. Res.* 15(4): 915-920. 1928.—Rats were fed a basic diet to which was added 1 gm. of whole rice raised under irrigation or 1 gm. of whole rice raised on dry land. The increase in body weight was markedly better in the group on the dry crop rice, though the food consumption was about the same. The author suggests that the difference is due to vitamin B content. Since beri-beri is prevalent in the northeast coast of the Madras Presidency where irrigation is used and is rare on the west coast where the dry crop method is employed, the suggestion seems logical.—*M. Fay.*

634. **MELLANBY, MAY. Periodontal disease in dogs (experimental gingivitis and "pyorrhoea").** *Proc. Roy. Soc. Med.* 23(11): 1503-1510. 4 fig. 1930.—Periodontal disease was produced or prevented in 30 or more experiments on dogs. Vitamin A deficiency is largely responsible for the overgrowth and abnormality of the periodontal epithelium and the corium. Vitamin D deficiency is responsible for defects in the hard periodontal tissues (alveolar bone, lamina dura, etc.). A deficiency of vitamins A and D during early life is of much greater significance than the same deficiency after the periodontal tissues are developed. Thus a defective diet during growth followed by a complete diet in maturity is more likely to lead to periodontal disease than a complete diet during development and a defective one during maturity. This may account for the presence of periodontal abnormalities in a human mouth where there is little or no caries, a condition which would be explained by the consumption of a diet poor in vitamin A but rich in D during development and eruption of the permanent teeth, but containing a liberal supply of both vitamins in later life. The addition of fat-soluble vitamin D to a diet checks the onset of dental caries even when the structure of the teeth is poor. In the experiments here discussed (a) injury to the gingival margin tends to induce local periodontal disease; (b) where tartar and dirt accumulate, periodontal disease is usually more emphasized, but which is cause and which effect it is impossible to say. Both tartar and periodontal disease are possibly produced by the same dietetic defects. The fact that two dietetic deficiencies may be concerned in the etiology of this disease, namely, deficiencies of vitamins A and D, seems to throw light on one of the controversies as to whether the pathological changes of the soft tissues precede the bony changes or vice versa. It is probable that either may occur first on the above hypothesis, although, as a practical fact of dietetics in England, a deficiency of A usually involves also a deficiency of D and vice versa.

635. **MORGAN, AGNES FAY, and ANNA FIELD. Vitamins in dried fruits. 2. The effect of drying and of sulfur dioxide upon the vitamin A content of fruits.** *Jour. Biol. Chem.* 88(1): 9-25. 1930.—The vitamin A content of frozen fresh and variously dried samples of peaches, prunes, and apricots was determined by uniform biological technique. The sulfured dehydrated fruit in all cases appeared to retain the largest proportion of the vitamin, but this retention was not directly related to the amount of SO_2 in the fruit. Of the unsulfured fruit, the sun-dried specimens of prunes and peaches showed better retention of vitamin A than did the corresponding unsulfured dehydrated products. Lye dipping of the dried prunes seemed to exert no effect upon vitamin A retention. The amount of destruction of vitamin A produced by comparable methods of preservation varied widely in the 3 fruits. The vitamin A of peaches seems little affected by any of the drying processes, 86-100% being retained in all cases. The vitamin A of prunes is more labile, 24-91% being retained, and that of apricots still more easily affected, only 16-51% of the fresh fruit value being present in the dried preparations. However, the dried apricots which had lost the greatest proportions of their fresh fruit vitamin A content were still absolutely richer in this vitamin than the best of the peach and prune products. Differences in amounts and kinds of oxidative catalysts present in the fruits are thought to account for these variations. Storage of both sulfured and unsulfured apricots and prunes at 0° for more than a year brought about no detectable loss of vitamin A content. The vitamin A content of 2 varieties of yellow peaches, of prunes, and of apricots is shown to be relatively large, that of the apricots comparing favorably with the best figures reported for spinach, egg yolk, or butter. The peaches and prunes had less vitamin A than the apricots but as much or more than tomatoes, bananas, or lettuce.—*Authors' summary.*

636. **NARAYANAN, B. T., and J. C. DRUMMOND. The concentration of vitamin B_2.** *Biochem. Jour.* 24(1): 19-26. 4 fig. 1930.—Fuller's earth absorbs vitamin B_2, at a pH of 0.05-0.10, but the absorbed active factor is difficult to remove. "Norite" is not an efficient absorbent. The active factor is insoluble in 70% alcohol. Vitamin B_2 is not destroyed by H_2O_2.—*E. B. Carmichael.*

637. **NELSON, E. M., and JOHN RUEL MANNING. Vitamins A and D in fish oils.** *Indust. & Eng. Chem.* 22(12): 1361-1363. 1930.—Tuna and sardine oils were

found to be as good as, or better than, cod-liver oil in vitamin D potency. Menhaden and salmon oils are also important potential sources of this vitamin. Salmon oil proved to be as potent in vitamin A as the poorer grades of cod-liver oil used for medicinal purposes. These results are important commercially because they point the way towards a potential domestic source of vitamin-bearing fish oils, whereas at present the United States is forced to import about 90% of the cod-liver oil used in animal feeding.—*Authors (courtesy Indust. & Eng. Chem.).*

Physiol.* 225(5/6): 582-590. 3 fig. 1930.—In a dog with duodenal and ileac fistulae and in a dog with jejunal and ileac fistulae, on vitamin-free diet, there was slight disturbance in absorption when the diet contained no fat, considerable disturbance when fat was added to the diet.—*From authors' summary (transl.).*

639. **NORRIS, EARL R., and ANNA E. CHURCH. A study of the antimony trichloride color reaction for vitamin A. 2. The dilution curve of cod liver oil with antimony trichloride reagent.** *Jour. Biol. Chem.* 87(1): 139-146. 1930.—A few of the various types of dilution curves which may be obtained with $SbCl_3$ and fish liver oils are shown. There is apparently no uniformity in type of dilution curve with various oils, and consequently it is impossible to make any comparison as to the vitamin A potency of the oil when the color produced is not a linear function of the amount of oil used. If the color produced with any oil were a linear function of the vitamin present and therefore of the amount of oil used it would coincide with the tangent to the dilution curve at the origin. The relative potency of vitamin A as shown by feeding experiments checks very closely with the relative color values of the tangent to the curve at the origin.—*Authors' summary.*

640. **NORRIS, L. C., G. F. HEUSER, and H. S. WILGUS, JR. Is the chief value of milk for feeding poultry due to the presence of a new vitamin?** *Poultry Sci.* 9(2): 133-140. 4 pl. 1930.—White Leghorn chicks were fed a ration consisting of yellow corn meal—64.5 parts, flour wheat middlings—20.0 parts, casein—11.0 parts, steamed bone meal—3.0 parts, cod liver oil—1.0 part, and salt 0.5 part. The ration contained 20.61% protein. The chicks were in 3 lots, 30 chicks in each. The rations of lots A and B were supplemented with a "milk vitamin concentrate" prepared by removing from milk the fat, casein, lactalbumin, nearly all the insoluble Ca phosphate and the greater part of the milk sugar, then concentrating the liquid remaining to the consistency of thick molasses. The ration of lot A was supplemented with 7.14% of this concentrate, and lot B received 2.68% of the concentrate. Lot C served as a control. The experiment was of 12 weeks duration. The rate of growth was greatest for lot A; least for lot C; while that of lot B was intermediate. Lot C developed an unusual paralysis, no lameness developed in lot A, and two cases occurred in lot B. "It is suggested, therefore, that milk contains a hitherto unrecognized factor, vitamin in nature, which is essential for the prevention of a peculiar type of paralysis in poultry involving the legs and feet, and which is indirectly growth promoting. The probability that the effects obtained from this factor have previously been credited to vitamin B is also suggested."—*A. D. Holmes.*

[Catamines and avian beri-beri.]** *Zymologica [Bologna]* 5(1): 13-17. 1930.—The author has studied the anti-beri-beri action of milk ferments in experimental avian beri-beri resulting from the Mattei diet (rice and decorticated sunflower seeds) and confirms the hypothesis of Mezzadroli of the existence of vitamine activity (catamine) in these ferments under the given experimental conditions. This may explain their sedative effect on the vegetative nervous system of the intestinal wall.—*A. Seppilli (transl. by P. Hillkowitz).*

647. **SHERMAN, H. C., and H. K. STIEBELING. Quantitative determination of vitamins A and D. II.** *Jour. Biol. Chem.* 88(3): 683-693. 1930.—Under suitable conditions and with the vitamin in question the first dietary deficiency, gain in weight in rats is the best measure for Vitamin A intake, and the degree of calcification the most practical measurement of Vitamin D intake. With young rats which have a considerable body store of these vitamins quantitative comparisons of the Vitamin A content of materials can be satisfactorily made by determining the amounts necessary to produce the same limited gain in weight (3 or 4 gm. per week during a test period from 5 to 8 weeks) in a sufficient number of suitably standardized rats receiving a basal diet free from Vitamin A, but otherwise adequate. Quantitative comparisons of the Vitamin D content may be made by finding the amounts of food (or other materials) necessary to induce a degree of calcification midway between the maximum values obtained by supplying Vitamin D liberally and the minimum values obtained by restricting as completely as possible the Vitamin D in comparable groups of animals. The actual percentage of Ca in the bones of such experimental animals depends on the nutritional history of each animal, its sex, and its age and weight at the beginning of the experiment, as well as on the mineral constituents of the diet and the length of the experimental period.—*H. K. Stiebeling.*

Dienst Volksgezondheid Nederlandsch-Indie* 19(1): 46-65. 1930.—The P_2O_5 estimation is no reliable standard for the anti-beri-beri vitamin percentage. A colorimetric method which is being developed and which has been applied to a few rice samples shows indices almost parallel to the animal-test.—*Author's summary.*

650. **STEENBOCK, H., E. B. HART, BLANCHE M. RIISING, C. A. HOPPERT, S. BASHEROV, and G. C. HUMPHREY. Fat-soluble vitamins. 28. The antirachitic value of cow's milk as modified by exposure of the cow to sunlight and to radiations from a quartz mercury vapor lamp.** *Jour. Biol. Chem.* 87(1): 103-126. 1930.—Daily exposure of cows to sunlight or artificially generated ultraviolet radiations has little if any effect on the antirachitic potency of milk. These experiments were carried out with Ayrshire and Holstein cows with coats for the most part unpigmented and with the radiations falling on the head, back, or udders, the latter being almost free from hair. The radiation period in some cases was continued for an hour daily at 20 to 30 inches with Cooper Hewitt or Alpine Sun lamps. Rats were used as the test animals for both prophylactic and curative technique. The results stand in marked contrast to our earlier observations with goats. No improvement in milk or butter fat secretion was observed. The well recognized superior quality of summer-produced milk and butter fat must therefore have its primary origin in other factors than sunlight acting directly upon the cow.—*Authors' summary.*

651. **STEENBOCK, H., E. B. HART, BLANCHE M. RIISING, S. W. F. KLETZIEN, and H. T. SCOTT. Fat-soluble vitamins. 29. Is antirachitic activation induced by ultra-violet radiations a panacea for negative calcium balances?** *Jour. Biol. Chem.* 87(1): 127-137. 2 fig. 1930.—In an experiment in which the utmost precautions were taken to exclude the consumption of activated compounds, it was found that direct exposure of a goat to the radiations of a quartz mercury vapor lamp increased the antirachitic value of its milk very decidedly. This was in direct contrast to our experience with cows. Yet in spite of this the goat ultimately showed a very decided negative Ca balance although originally with the beginning of irradiation a slight improvement in Ca retention resulted. In view of a simultaneous increase in the restlessness of the animal with the incidence of a pronounced negative Ca balance, it appears that the elimination of Ca may be controlled neurologically as well as by the antirachitic factor. Whether or not this is effected directly or through some other mechanism, as for example the parathyroid glands, is not known. Antirachitic activation therefore cannot be considered a panacea for a disturbed Ca metabolism.—*Authors' summary.*

652. **STEENBOCK, H., E. B. HART, FLORA HANNING, and G. C. HUMPHREY. Fat-soluble vitamins. 30. The antirachitic value of cow's milk as modified by the feeding of irradiated yeast.** *Jour. Biol. Chem.* 88 (1): 197-214. 1930.—50 gm. of irradiated yeast fed to cows increased the antirachitic potency of milk. Even 200 gm. of yeast did not lower the milk production nor did it decrease the butter fat content. When the amount of yeast was reduced to 10 gm. daily, a slight effect on the antirachitic potency of the butter fat was still noticeable. This effect was not clearly demonstrable on the milk. 180 gm. of cod liver oil produced results similar to 10 gm. of yeast. It appears that the feeding of a standardized irradiated yeast may be considered as a practical measure for the production of a milk of standard antirachitic potency. It remains to be demonstrated whether irradiated yeast can be effectively used for the same purpose in the human dietary.—*Authors' summary.*

653. **STIEBELING, HAZEL K. Studies of the relation of vitamin D to the deposition of calcium in the bones of experimental animals with special reference to the quantitative determination of vitamin D.** 24p. Dissertation, Columbia University: New York, 1928.—Young white rats reared by mothers receiving a ration consisting essentially of ¾ ground whole wheat and ¼ whole milk powder, were placed when 3 to 4 weeks old on a diet, good in other respects but decidedly deficient in Vitamin D. This diet consisted of fat-soluble-vitamin-free casein, 18 parts; powdered dry yeast 10 parts; Osborne and Mendel salt mixture 4 parts; powdered dry spinach 1 part; NaCl 1 part; and cornstarch 66 parts. From that time until the 56th day (the 80th day of age), comparable groups received graded allowances of Vitamin D (whole summer milk powder) or a definite amount of ultraviolet irradiation. The percentage of Ca in the body (or femur) was, on the average, proportional to the allowance of Vitamin D supplied, within a range of values to which the animal body is sensitive. Averages were based on groups carefully matched at the beginning of the test as to nutritional history, sex, and weight. Extensive data were accumulated indicating that as a measure of the degree of calcification under these conditions, the percentage of Ca (or ash) in the fresh femur may be quite as satisfactory as the percentage of Ca (or ash) in the dried extracted bone, or the ratio of ash to the organic residue of the bone.—*H. K. Stiebeling.*

Kl.* 1929 (3): 169-172. 1929.—The author's hypothesis is, that if multiple unsaturated hydrocarbons are differentiated by their absorption spectra, the one with the largest absorption coefficient, and absorbing in the region of longest wave length, will most likely contain conjugated double bonds. The presence of conjugated double bonds becomes much more probable if the material, in contrast to its isomers, takes up 2 atoms of hydrogen when hydrogenated with alcohol and sodium. Ergosterol has this property. It has been shown by others that a conjugated system of double bonds is able to form an additive product with maleic acid anhydride. Of all the compounds in this group that were investigated, only dehydroergosterol forms an additive product with maleic acid. It is concluded that this compound is the only one that contains a conjugated system, the double bonds of which occur in one ring.—*A. G. Hogan.*

661. **ALVAREZ, WALTER C., and KIYOSHI HOSOI, (with the technical assistance of MILDRED FOSTER and E. C. WOOLLEY). Conduction in different parts of the small intestine. I. Distance traversed by a disturbance and rate of travel.** *Amer. Jour. Physiol.* 94(2): 448-458. 4 fig. 1930.—The small intestine of rabbits was stimulated with a faradic tetanizing current and records were obtained of the local contraction and of the disturbance which spread orad and caudad. Make and break faradic and galvanic stimuli produced a local contraction but little or no sign of a traveling disturbance. Interrupted galvanic stimulation produced effects similar to those of alternating faradic stimulation. After faradic stimulation a disturbance traveled orad from 1 to 15 cm. and caudad from 1 to 20 cm. The modal distance orad was 5 cm. and the modal distance caudad was 10 cm. The best conduction was seen in the duodenum. In a few animals a disturbance could be detected 40 or 50 cm. caudad to the point stimulated. Such conduction was rapid and was mediated probably by nerves in the mesentery. The response to electric stimulation of the rabbit's bowel is practically always contraction locally and orad and caudad. Bayliss and Starling's law does not hold true for the rabbit. Occasionally after traveling a short distance as a wave of contraction the disturbance produced by an electric stimulus manifested itself as a wave of relaxation. In the intact bowel the rate of conduction varied from 1 to 13 cm. a sec. with a mode about 2.5 cm. The mean varied from 5 cm. a sec. in the duodenum to 3.8 cm. a sec. in the terminal ileum. In excised bowel the mean rate varied from 7.2 cm. a sec. in the duodenum to 6.0 cm. a sec. in the terminal ileum. In both intact and excised gut the rate caudad was a little faster than the rate orad. Conduction in the wall of the bowel appears to take place by way of nerves which are sluggish like those in lowly forms of life.—*Authors' summary.*

Über den Cholineinfluss auf die motorische Funktion des Dünndarms.** *Pflüger's Arch. Ges. Physiol.* 222(5/6): 656-661. 3 fig. 1929.—Intravenous injection of choline in doses of 0.5-30.0 mgm. into decerebrate cats produced in 64% of the cases studied by the methods described in preceding papers a single strong contraction of the intestine followed by a depression of the tonus either to normal or below. In the other cases the response varied from a positive inhibition to a series of powerful contractions. The character of the reaction and the sensitiveness of the intestine to choline injection varied widely in the same experiment. The authors conclude that while choline may have been a constituent of the solutions used in their previous work other substances were present which complicated the results.—*C. S. Robinson.*

666. **BASCH, FELIX, und HANS MAUTNER. Experimentelle Beiträge zur Lehre von der Resorption.** *Arch. Exp. Pathol. u. Pharmakol.* 151(1/2): 76-90. 1930.—In rats gastric absorption and secretion are increased by vagus stimulation. The sympathetic system acts antagonistically. After atropine, epinephrine, ergotamine and their various combinations the stomach always remains fuller than in the controls. For the final effect of absorption increased peristalsis is unfavorable, while in the intestines increased peristalsis and secretion increase absorption. The best absorption was of isotonic in contrast to hypertonic and hypotonic solutions.—*H. Graf.*

667. **BERNARDI, A., e M. ŽANINI. Contributo allo studio dei fermenti contenuti nel ventriglio di pollo e di rondine di mare (Hydrochelidon nigra L.) Nota IV. [The ferment contents of the proventriculus of chicken and the sea swallow, H. nigra.]** *Biochim. e Terapia Sperim.* 17(1): 6-15. 1930.—Amylase which could be extracted with glycerol was present in the mucous membrane of the proventriculus of chickens. Its activity increased first to a maximum; then decreased to a minimum, and increased again to a maximum. An amylase was present also in the mucous membrane of the proventriculus of *H. nigra.* Its activity, after increasing slowly at first, reached a maximum, and then decreased until action ceased. An invertase was present in chicken, but not in the mucous membrane of the proventriculus of *Hydrochelidon.*—*M. Comel.*

ischen Wirkungen von Infusen aus Röstprodukten der Zerealien und Zichorienwurzeln auf die Magen-Darm-Funktionen. [Physiologic effects on stomach and bowel of infusions of roasted coffee substitutes.] *Arch. Verdauungs-Krankh.* 46(1,2): 1-13. 1929.—The substitutes for coffee have a slightly stimulating effect on gastric secretion. Some of them increase also the tone of the intestinal muscle. Chicory does not have this effect on the muscle.—*W. C. Alvarez.*

669. **BONIS, A. Magenschleim und Säurebindung. Zugleich ein Beitrag zur Titration mit Indikatoren und zur elektrometrischen Titration des Magensaftes.** *Zeitschr. Klin. Med.* 113(5/6): 611-620. 1930.—The sources of error in the 2 methods of titration are critically discussed. Comparative study of unchanged with sedimented, filtered and dialyzed gastric juice indicated that mucus plays an insignificant part in the neutralization of acid, and that the production of mucus probably merely affords mechanical protection to the gastric mucosa. The available facts suggest an antagonistic regulation of the mucus-acid secretion.

670. **BRENCKMANN, ERNEST. Contribution à l'histophysiologie de la muqueuse gastrique en rapport avec l'élimination de l'HCl. Considérations générales sur le problème de l'ulcère.** 110p. 21 fig. Universitaires de Strasbourg, 1929.—This treatise presents a series of physiological and histological observations of the processes concerned in the mechanism of production of the HCl by the gastric mucosa (dogs) and gives a very brief discussion of the phenomena of duodenal regurgitation. The author attempts also to correlate some experimental procedures (sham-feeding) with the hypersecretion of gastric juice and the latter is considered as a contributing factor in the formation of gastric ulcer. The gastric mucosa is subdivided into 4 parts: (1) The air pocket, (2) The central fundus, (3) A narrow transitional antrofundal zone and (4) The pyloric antrum. The secretory work of the stomach was studied by the method of topographic investigation based on the results of macroscopic and microscopic examination of gastric mucosa. Applying $K_4Fe(CN)_6$ and $FeCl_3$ to the interior surface of the stomach and observing the formation of Prussian blue, Brenckmann reports that the mucosa of the air pocket is characterized by comparatively weak vascularisation, by its thinness and by abundance of connective tissue. This zone does not participate in the secretory process during digestion, but is potentially a secretory zone since under the influence of histamine it becomes involved in the production of HCl. The central fundus is the part of the gastric mucosa which plays the most active rôle in the secretory work of the stomach. In new-born animals this secretory zone is reduced to two patches situated on both sides of the smaller curvature near the antrum. Neither HCl nor pepsin could be demonstrated in the stomach of a full term fetus (guinea-pig) after the injection of histamine into the mother. In the adult animal the surface cells of the fundal mucosa are the most actively involved in the secretory work, the middle cells show much delayed response and the lower cells of the glandular tube remain in a state of permanent rest. The transitional zone is located between the fundal and antral zones (1 to 3 cm. wide) and presents the same histological aspect as the fundal mucosa of the air pocket. The pyloric region is free from parietal cells. The zone of the most typical mucosa of the central fundus is about 2-3 cm. from the antrum. The number of chief cells is greatly augmented in this region and the Prussian blue reaction is uniform and constant. Recently Lim and Ma observed the changes of the mitochondrial apparatus in the cells of the gastric mucosa after feeding or after the injection of histamine and arrived at the following conclusions: The chief cells are filled with pepsin zymogen granules in a state of rest. During the digestion these granules disappear, new ones are formed and finally, if the secretion of pepsin is continued, the cells become free from granules. In proportion to the disappearance of zymogen granules the mitochondria and ergastoplasm appear in the chief cells. It is surmised that the ergastoplasm which appears at the base of the cell serves for the formation of the thread granules. The author's data are in accordance with this statement. One certainly cannot agree with the author's belief that in his experiments the "sham-feeding" was responsible for acute hemorrhagic gastro-duodenitis, atrophy of the glandular cells and extreme vasodilatation of blood vessels. Animals subjected to daily "sham-feedings" live for many years in a condition of perfect health in other laboratories. The author's experiments for the purpose of studying duodenal regurgitation were too crude and as he himself admits they failed for that reason. Duodenal regurgitation is a normal physiological process well established and generally recognized.—*E. B. Boldyreff.*

671. **CHILDREY, JOHN H., WALTER C. ALVAREZ, and FRANK C. MANN. Digestion: efficiency with various foods and under various conditions.** *Arch. Internal Med.* 46(3): 361-374. 1930.—These studies continue and amplify those published by Hosoi, Alvarez and Mann [*Arch. Internal Med.* 41: 112. 1928.] The authors sought to improve intestinal absorption by giving food in a number of portions at intervals, and tried mincing the food and slowing the progress of peristalsis with morphine. They also tested the effect of giving progressively larger amounts of foods. Would the efficiency of digestion fail gradually at a certain point or break suddenly? The amount of residue obtained after the digestion of various foods was studied in 6 dogs, all deprived of the colon. The foods best digested were meat, rice, dextrose and fat in small amounts. These foods might well be used in the treatment of patients with diarrhea, and in the preoperative or postoperative care of patients with serious diseases of the colon, rectum or anus. The combining of certain foods, such as bread and milk and raw egg and milk, improved the digestion of both substances. Lactose, in considerable amounts, proved to be a laxative which interfered not only with the digestion of food eaten the same day but also with the digestion of food eaten the following day. Cheese and lard given one day also interfered with the digestion of food eaten the following day. Meat was better digested when given in lumps than when given finely comminuted. The same was true of Swiss cheese. Raw meat was better digested than cooked meat. Except in case of a few foods, it was difficult to give so much that the efficiency of digestion would fail. The dog usually protected himself by vomiting part of the meal. Raw egg when not mixed with other foods was highly indigestible. Raw cornstarch given alone was almost completely indigestible. The addition of lemon juice to food hurried the progress of residue through the bowel and interfered somewhat with the efficiency of digestion. Orange juice had little effect on digestion. Pie crust did not seem to be much more indigestible than white bread. It was more digestible than Graham bread. Anxiety and excitement influenced adversely the efficiency of digestion. Food when taken in one large amount was better utilized than when taken in several fractions at half-hourly intervals. Apparently each feeding stimulated peristalsis and caused the food to pass too rapidly through the bowel. It had little effect on the digestion of ground cooked meat, given at the same time, but it interfered with the digestion of meat given the next day.

672. **CONTI, FRANCESCO. Contributo al meccanismo dell'iperglicemia alimentare. Influenza dell'innervazione epatica. [The mechanism of alimentary hyperglycemia and the influence on it of denervation of the liver.]** *Policlinico [Sez. Med.]* 37(4): 183-196. 1930.—In 8 dogs the curve of alimentary hyperglycemia was studied before and after the vegetative nervous system had been paralyzed by ergotamine and atropine. The reaction was not uniformly affected by the drugs, but in no case was the hyperglycemic reaction to administration of glucose abolished, as reported by Pollak for rabbits. In 5 dogs in which the blood-sugar curve following ingestion of glucose was taken before and after denervation of the

liver, the curve subsequent to the operation was distinctly lowered and flattened. Conti rejects the hypothesis that this depression of the glycemic curve may be due to changes in the intestinal capillary system retarding the absorption of glucose, because in that case the hyperglycemia, though lower, would be more protracted than under normal conditions, whereas in his experiments the blood sugar returned to normal as promptly in denervated as in normal dogs. The hypothesis that the lowered hyperglycemia might be due to disturbances in intrahepatic circulation tending toward greater fixation of the sugar in the hepatic cell was tested by injection of glucose into a portal root before and after hepatic denervation; in 2 experiments reported, no deviation of the hyperglycemic curve from the normal followed denervation under these conditions. Hence Conti concludes that alimentary hyperglycemia is due in part to a nervous stimulus produced by action of the ingested glucose on the intestinal mucosa; but, since the hyperglycemic response is not abolished, but merely reduced, by denervation of the liver, some other as yet unknown factor must be concerned, possibly hormonal or perhaps direct passage of exogenous sugar into circulation.

673. **CORI, GERTY T. Studies on intestinal absorption. 1. The absorption of lactic acid.** *Jour. Biol. Chem.* 87(1): 13-18. 1930.—Absorption of *dl*-lactic acid (fed as sodium salt) from the intestinal canal of rats was determined 1, 2, 3, and 4 hrs. after feeding the same amount per weight. It was found that the rate of absorption decreased with time and was roughly proportional to the amount of lactic acid present in the intestine. Attention was drawn to the fact that the mechanism of absorption of lactic acid differs from that observed for sugars and amino acids. With these two groups of substances the rate of absorption is within wide limits independent of the amount present in the intestine. Slow evacuation of the stomach can limit the rate of absorption of lactic acid in a certain number of cases. From a solution containing lactic acid plus glucose both substances were absorbed at rates below those observed when pure solutions were fed.—*Author's summary.*

674. **CORI, CARL F., EDWARD L. VILLIAUME, and GERTY T. CORI. Studies on intestinal absorption. 2. The absorption of ethyl alcohol.** *Jour. Biol. Chem.* 87(1): 19-25. 1930.—The rate of absorption of alcohol depends on and is roughly parallel to the amount fed. Up to a 20% solution the concentration has little influence on the rate of absorption. From a 40% solution alcohol is absorbed more slowly than from a 20% solution due to slow evacuation of the stomach. Separate analysis of stomach and intestine shows that the latter contains as a rule only 12 to 56 mgm. of alcohol irrespective of the amount of alcohol fed or absorbed or of the amount of alcohol present in the stomach. This small residual quantity of alcohol which seems to be contained mostly in the intestinal wall disappears very slowly. The fact that the small intestine always contains but this small residual amount indicates that alcohol is absorbed as rapidly as it leaves the stomach. The rate of emptying of the stomach is therefore the determining factor for the rate of absorption of alcohol. Massage of the stomach which accelerates the passage of alcohol into the gut also accelerates the rate of absorption. An upper limit of the rate of absorption in the small intestine cannot be determined because the animal dies of alcohol intoxication before such a limit is reached. Small quantities of alcohol do not accelerate the absorption of glucose from the intestine of rats.—*Authors' summary.*

675. **DANNINGER, RUDOLF, KARL PFRAGNER, und HANS SCHULTES. Über die absolute Reaktion in dem Inhalt der einzelnen Darmabschnitte von Pferd und Rind.** *Pflüger's Arch. Ges. Physiol.* 220(1/6): 430-433. 1928.—The gas-chain method was used in determining the pH of intestinal contents removed from horses and cattle immediately after death in the slaughter-house; duodenum, jejunum, ileum, and cecum were separately studied. In both species the cecal contents were alkaline (horses 8.125, cattle 8.224); the contents of the equine ileum were neutral while those of the bovine ileum and jejunum were still alkaline; and the duodenal contents of both species fluctuated about neutrality with a tendency to be acid.—*F. T. Jung.*

678. **FENG, TEH-PEI, HSIANG-CH'UAN HOU, and R. K. S. LIM. On the mechanism of the inhibition of gastric secretion by fat.** *Chinese Jour. Physiol.* 3(4): 371-379. 1929.—Experiments on dogs are reported, which show that the ingestion of fat causes inhibition of the secretion of completely denervated (auto-transplanted) gastric pouches. This not only indicates that the extrinsic nerves are unessential for inhibition but definitely implies a humoral mechanism. The intravenous injection of thoracic lymph collected after a fat meal does not inhibit gastric secretion, nor does the institution of a lymph fistula, so that the chyle no longer drains into the circulation, affect the course of secretion. Thus fat itself is not the inhibitory agent, nor is the agent transmitted through lymphatic channels.—*Authors' summary.*

679. **FISCHL, E., und R. H. KAHN. Die amylolytische Wirksamkeit des Kaninchenspeichels.** *Pflüger's Arch. Ges. Physiol.* 225(5/6): 694-698. 1930.—The oral saliva of 30 rabbits studied in 117 experiments by the methods of Wohlgemuth and Biedermann gave amylolytic values corresponding throughout to those of human oral saliva. Extirpation of the submaxillary and sublingual glands had practically no effect on the amylolytic action, while extirpation of both parotid glands rendered the saliva almost or quite inactive. In 6 starved rabbits the activity of the saliva was markedly increased the 1st day of hunger, with later a slow decrease, but not to entire inactivity as reported by Gayda for the 15th day. The variations in amylolytic activity of rabbit saliva ran parallel with the variations in dry substance content.

680. **GANTT, W. HORSLEY. Salivary secretion and the intake of fluid.** *Amer. Jour. Dis. Children* 37(6): 1125-1127. 1929.—Gantt studied effect of normal and forced fluid intake and of thirst on the parotid and submaxillary secretions when the subject was shown food for 30 sec. and when given food to eat. Parotid secretion decreased in thirst and slightly increased on forced fluid intake. An epileptic fit decreased unconditioned salivary secretion in all cases. Submaxillary secretion decreased in thirst; unconditioned and conditioned reflexes were decreased in thirst.—*M. R. Freeland.*

(Son absence chez un cocaïnomane présentant une anesthésie du voile du palais.)** *Lyon Méd.* 143(19): 580-584. 1929.—The patient had anesthesia of the pharynx. An Einhorn tube was passed without the usual discomfort, and did not produce the usual secretion of gastric juice, while wine caused a normal response. This is further proof that the passage of the tube causes a secretion of gastric juice.—*M. G. Mulinos.*

682. **GROEBBELS, FRANZ. Die Verdauung bei der Hausgans, untersucht mit der Methode der Dauerkanüle.** *Pflüger's Arch. Ges. Physiol.* 224(6): 687-701. 4 fig. 1930.—Permanent cannulas were inserted in the duodenum, pylorus, gizzard and glandular stomach in 14 geese; studies were made on the digestion of oats, barley, maize, potatoes, bread, bran and yellow turnips. (1) Mechanics: The goose has no pyloric reflex; there is no constant relation between the mechanical con-

traction of the muscular stomach and the exit of food. The duration of passage of equivalent amounts, reckoned in dry substance, varies with the consistency of the foodstuff, following the order: grains, potatoes, bread. Parching or grinding oats did not alter the duration of passage. Forced feeding lengthened the passage of food. The grinding sound from the gizzard was always present and frequently repeated after grain feeding (even when food had reached the glandular stomach), sometimes absent and less frequently repeated after bread feeding, generally absent after potato feeding. The presence of a cannula in the gizzard disturbed its mechanical action. Sand and pebbles left the gizzard in large quantities during the first 2-3 hrs. after grain feeding; the amount was variable after bread feeding, the amount during the first 2 hrs. being small; only a small amount left the gizzard at the beginning of the experiment after feeding potato. Fluids passed through both stomachs without delay. (2) Chemistry: In the goose the back-flow of digestive secretions is physiological. Bile flows into the glandular stomach, amylase into the gizzard. The digestion of carbohydrates begins in the gizzard, that of protein in the glandular stomach, and apparently food can be impelled forward and back between the 2 stomachs. There is no regular connection between secretion of bile and pancreatic juice and exit of the food from the gizzard. In like experimental animals and for equivalent amounts of dry substance the amount of secretion follows the order: potatoes, oats, barley, maize, bread. Parching or grinding the oats does not change the amount of secretion; but it is distinctly lowered by forced feeding, considerably lowered after a 4-day fast. The amount of secretion varies according to the amount of food with potatoes and bread, but not with oats. Much gastric juice and bile are secreted after potato feeding, much bile after bread, little gastric juice and much pancreatic juice after yellow turnips.

Med.* 107(6): 700-715. 1928.—It is found in general that the Rosenthal test with phenoltetrachlorphthalein and the van den Bergh direct reaction go hand in hand. In a doubtful case either will supplement the other. There is a long discussion of the various modifications of the van den Bergh reaction.—*C. H. Greene.*

684. **HOWLAND, RUTH B. The pH of gastric vacuoles.** *Protoplasma* 5: 127-134. 1 fig. 1928-1929.—*Actinosphaerium eichhornii* may enclose in its gastric vacuoles, ciliates (usually hypotrichs), rotifers and nematodes, which remain alive after incorporation. The pH of the vacuole fluid in a newly formed vacuole containing live food is, for a period of 5-10 min., neutral or slightly acid, i.e., 6.6 to 7.0. With decrease in pH, the activity of live prey decreases, until it becomes motionless. The length of time elapsing before this occurs is variable. In the case of ciliates this occupies but a few minutes, while rotifers may live for several hrs. It is possible, therefore, that the acid functions as a killing fluid within the vacuole. The pH of all gastric vacuoles containing food in the process of active digestion is 4.3 ± 0.1. Old vacuoles containing indigestible residuum usually have a pH value of 5.4 to 5.6. More rarely these may register 6.8 to 7.0.—*Author's summary.*

685. **JARNO, LEO. Das Problem der duodenalen Regurgitation.** *Arch. Verdauungs-Krankh.* 45(1/2): 50-56. 1929.—This is mainly a discussion of the possible effects of bile and its constituents in the stomach.—*W. C. Alvarez.*

Zeitschr.* 201(1/3): 199-205. 1928.—The assimilation of Ca by the musculature of the small intestine of the cat, rabbit, guinea-pig, and rat under the action of adrenaline is not regular and can occur without adrenaline when the intestine is paralyzed by other causes. The irregularity of this phenomenon is not an argument for the theory of a vegetative irritation by the ions.—*H. Pribram.*

687. **KATZENSTEIN, MARGARETE. Untersuchungen über Speichellipase.** *Zeitschr. Ges. Exp. Med.* 69(1/2): 179-192. 1 fig. 1929.—A series of studies on salivas sustains the findings of Scheer and his collaborators of a fat-splitting ferment in oral saliva. This lipase has no connection with bacterial effects; it is more abundant in parotid secretion than in the total saliva. It is most effective at pH 7.5-7.7, the physiologic pH of human saliva. This paper is a report of study of the lipase content of salivas in various diseases. In diseases in which the flow of saliva is increased (as in certain cases of stomatitis, abscess of cervical glands, Vincent's angina and Feer's disease or vegetative neurosis of childhood) the lipase content was usually low. In the diseases in which the flow of saliva was reduced (paradentosis, gingivitis, measles, varicella and diabetes mellitus) the concentration of lipase was increased. The lipase-content in scarlatina was variable. Experiments on the dog showed a lipase in the total saliva; no noticeable difference was observed in the pure parotid secretion.—*Author's summary (transl.).*

688. **KOKAS, E. von, und G. von LUDÁNY. Weitere Untersuchungen über die Bewegung der Darmzotten.** *Pflüger's Arch. Ges. Physiol.* 225(2/3): 421-428. 1 fig. 1930.—When dogs were fed 2-3 hrs. before the experiment, movements of the villi were visible, often even to the naked eye, on opening the intestine under narcosis. In a hungry animal the movements could be elicited only by artificial stimulus. In a dog which had been fed, when a loop of intestine had been tied off, movements of the villi were discernible only where intestinal contents were present and resorption was going on. Villous movements were observed after detachment of a segment of intestine from the animal, indicating that the lengthening of the villus is not the result of an influx of blood nor probably of a hydrostatic increase of pressure in the central lymph-space; but rather of a local chemical stimulus connected with resorption. After detachment of the mucous membrane from the muscularis mucosae, and thereby from the plexus of Meissner, the movements of the villi ceased, indicating that the center of villous movement is to be sought in Meissner's plexus.

697. **MANGOLD, E., und K. HAESLER. Der Einfluss verschiedener Ernährung auf die Grössenverhältnisse des Magendarmkanals bei Säugetieren (nach Versuchen an Ratten).** *Wissensch. Arch. Landw. Abt. B. Tierernähr. u. Tierzucht* 2(3): 279-305. 1 fig. 1930.—There having been observed in swine a distinct, though small, influence of type of ration (non-bulky-animal and bulky-vegetable rations) on the size relations of the digestive tract, a similar study was made on rats. In 9 experiments on 64 animals in groups of 2-3 animals each from the same litter, during growth up to 200 gm., tests were made of the intravenous injection of alanine, glycoll and relative weight, capacity, and length of sections of the digestive tract. Each group received a purely plant, purely animal or mixed normal ration; within these categories the feed for 2 groups was made bulky by addition of cellulose or loam. The differences between groups due to the 9 kinds of feeding were less than for swine. In many cases the impression of distinct difference gained from the general average for different feeding categories was dispelled by comparison of individual groups. The greatest change was a fairly constant increase in weight and volume of large intestine and weight decrease in small intestine. Under animal diet there was distinct volume reduction of cecum and indication of volume increase of small intestine. The absolute length of small intestine was increased by animal diet and reduced by vegetable. In relation to length of body, the lengths of small and large intestine were unaltered and the whole intestine tended to be shorter than normal under both animal and vegetable diets. Males exceeded females in total length as compared with body length. The differences between vegetable-, animal-, and normal-fed rats were themselves so small that within these categories no influence of bulk, to say nothing of different effect of loam and cellulose, appeared.—*Authors' summary (transl. by M. H. Keith).*

698. **MEYER-BISCH, ROBERT. Ueber die Regulation der Pankreassekretion durch das Blut.** *Verhandl. Deutsch. Ges. Inn. Med.* 40(Kongress): 254-258. 1928.—The action of the intravenous injection of alanine, glycocoll and cystine on the composition and speed of outflow of the pancreatic secretion is studied. Hypertonic NaCl solution enhanced the concentration of chloride in the pancreatic secretion out of proportion to the increase in the blood. The N content underwent similar changes. The output of the secretion decreased. $NaHCO_3$ induced regular increase of the chloride content, whereas the amount of the secretion varied in different animals. The injection of alanine, glycocoll and cystine was followed by cessation of the secretion for as long as 50 min. in some experiments. The secretion after the suspension also contained more chloride than the initial secretion. The clinical significance of this study lies in the finding that certain substances which vary quantitatively in blood in connection with food intake, may have definite physiological effects.—*S. Katzenelbogen.*

699. **NEVER, HENRY E. Speiseregime und Sekretionstätigkeit der Verdauungsorgane.** *Pflüger's Arch. Ges. Physiol.* 225(1): 51-55. 4 fig. 1930.—Meat was fed for about 4 wks. to 2 dogs with gastric and duodenal fistulae; then bread and potatoes were fed for 4 wks. At the test mealtimes the digestive juices were collected at the fistulae and quantitatively determined. The different diets had no effect on the secretion of the digestive juices.—*Author's summary (transl.).*

700. **POESCHEL, RUDOLF. Untersuchungen über die Magenfunktion bei magengesunden alten Leuten.** *Zeitschr. Klin. Med.* 113(3/4): 379-388. 1930.—Fractional extraction of gastric contents showed, in 30 old people without gastric disorders (14 ♂♂ and 16 ♀♀), a tendency toward anacidity in the gastric juice (supporting the findings of Seidelin in 1904); the proportion of anacid cases rose with advancing age. The presence of large amounts of mucus suggested a chronic gastritis, though no complaints referable to such a condition were encountered. No difference between the reaction of ♂ and ♀ was apparent. The chemical character of the contents of the fasting stomach (secretion) corresponded in a general way to the results of the reaction. The time of gastric evacuation is quite various in old age, but not shortened. Poeschel concludes that anacidity cannot be diagnostic of gastric cancer in old age.

701. **POPOW, N. A., und A. A. KUDRJAWZEW. Über den Einfluss der Reaktion der Erreger der Speichelabsonderung auf die aktive Reaktion des Speichels.** *Pflüger's Arch. Ges. Physiol.* 224(1): 69-71. 1930.—The pH of saliva of the parotid gland of 2 dogs, after acid or alkali administration, was taken by both a pear-shaped and a U-shaped electrode. With a pear-shaped electrode the average pH of the saliva of the dogs after acid administration (0.5% HCl) was 8.83 and 9.24 respectively; after alkali administration (.10% Na_2CO_3 or .25% NaOH) it was 8.76 and 9.15 respectively. With the U-shaped electrode after acid administration the pH of the saliva was 8.25 in 1 dog and 8.45 in the other; after alkali administration 8.17 and 8.32 respectively.

702. **POPPER, HANS L., und ALFRED SELINGER. Zum Nachweis von Pankreasfermenten in der Galle. Einwirkungen auf Leber, Gallenwege und Pankreas.** *Zeitschr. Klin. Med.* 113(3/4): 389-394. 1930.—In previously published work Popper had shown the presence of diastase in the bile of the gall-bladder in about 20% of cases; when the arrangement of the duct orifices permits, the pancreatic ferment passes direct from the pancreatic duct into the bile-duct and thence into the gall-bladder. Westphal has expressed the opinion that this pancreatic juice produces injurious changes in the biliary passages and in the liver. To settle this question Popper and

Selinger have studied 14 patients in whom cholecystectomy or other operative procedure had produced for a length of time varying from 14 days to 13 months intermingling of pancreatic juice with the bile of the gallbladder. They found no injury to the biliary passages or the liver and no special disposition to acute pancreatitis. They conclude that so-called non-perforating biliary peritonitis must be referred to a cause as yet unknown, and that the mixture of bile and pancreatic juice after cholecystectomy causes no postoperative difficulties.

703. **PRIKLADOWZKY, S., und M. BRESTKIN. Äussere Sekretion der Verdauungsdrüsen und Blutchemismus. I. Mitteilung. Alkalireserve und Chloride im Blut.** *Zeitschr. Ges. Exp. Med.* 64(3/4): 494-505. 8 fig. 1929.—In sham feeding experiments on esophagotomized, gastric-fistula dogs it is shown that gastric secretion is accompanied by increase of the alkali reserve of the arterial plasma, conversely alkaline secretion (pancreas) results in decreased alkali reserve. The changes in normal dogs depend on the food given: lean meat, a sharp increase in alkali reserve returning to near fasting level in 4-5 hrs.; bread, a more prolonged but smaller increase; and fat, an initial decrease followed by a definite increase over the fasting value. Practically always, the blood chloride falls during the height of the increase, and rises during the decrease of the alkali reserve.—*M. H. Power.*

704. **RADEFF, T.** Смилаемостьта на суровата целулоза на зърнинитѣ храни при гжлаба. [The ability of pigeons to digest the crude fiber of cereals.] Годишникъ на Софийския университетъ, Ветеринаромедицински факултетъ (*Jahresber. Univ. Sofia, Vet. Fakultät* 5: 261-270. 1 fig. 1929.—A male and female white pigeon were unable to digest the crude fiber of rye. The crude fiber of wheat was digested to the extent of about 2%, that of barley about 11% and of maize about 10.6%. These experiments show that the functions of the cecum of fowls in the digestion of crude fiber can, in pigeons, be taken over by other sections of the alimentary tract.—*A. Kalojanoff* (*transl. by C. S. Robinson*).

705. **SCHREIBER, BRUNO. Studi sull'assorbimento intestinale nelle Oleturie. [Intestinal absorption in Holothurians.]** *Pubbl. Staz. Zool. Napoli* 10(2): 235-277. 1930.—In vitro studies on the semipermeability of Holothurian intestines show with regard to the nature and cause of this permeability that under certain conditions they are permeable to isotonic glucose solutions. Semipermeability may be considered as a pathological manifestation of the intestine in probable relation to the high temp. to which the animals were subjected while still living. In experiments of long duration, one observes a series of variations in permeability interpretable as a proof of the vitality of the mucosa during the phase of penetration.—*B. Schreiber* (*transl. by J. G. Edwards*).

706. **SHAFFER, PHILIP A., and THEODORE E. FRIEDEMANN. Sugar activation by alkali. I. Formation of lactic and saccharinic acids.** *Jour. Biol. Chem.* 86(1): 345-374. 3 fig. 1930.—Amounts of saccharinic and lactic acids formed from hexoses, pentoses and trioses under influence of varying conc. of KOH are reported. High alkalinity favors high, temp. and high sugar conc. lower, yield of lactic acid. Within limits, yield of lactic acid from glucose appears to be a function of a fraction of sugar in form as a salt. At high alkalinity and low sugar conc. dihydroxy acetone is almost quant. conv. to lactic acid, yield being a function of the triose, calc. for an assumed pK value of 12.80. Concl. alk. and temp. "activate" sugars by salt formation and consequent ionization, and saccharinic acid formation may be regarded as spontaneous rearrangement of unstable sugar ions. Ratio of particular acids formed probably depends upon the proportions of different salts or ions.—*M. R. Freeland.*

707. **TSCHUKITSCHEFF, I. P. Über den Mechanismus der Hungerbewegungen des Magens. II. Der Einfluss humoraler Verdauungsagentien auf die periodische Tätigkeit des Magens.** *Pflüger's Arch. Ges. Physiol.* 225(5/6): 769-781. 5 fig. 1930.—Pancreatic secretin, injected into the blood, would always, after 1 or 2 min., stop the gastric hunger contractions. Similar injections of certain amino acids had no effect. Injection of the end-products of digestion of fibrin by gastric juice, or first by gastric juice and later pancreatic and intestinal juice, caused inhibition of hunger movements. Injection of the blood of hungry animals increased hunger contractions. The author believes that the intensity of hunger contractions is a function of protein metabolism.—*W. C. Alvarez.*

708. **VERZÁR, F., und A. KÜTHY. Die Verbindung der gepaarten Gallensäuren mit Fettsäuren und ihre Bedeutung für die Fettresorption. II. Löslichkeit und Diffusibilität.** *Biochem. Zeitschr.* 210(4/6): 265-280. 5 fig. 1929.—In a previous paper it was shown that the alkaline salts of the coupled bile acids—Na taurocholate and Na glycocholate—are able to bring finely dispersed fatty acids into a clear watery solution. Such solutions have two qualities of biological importance. The fatty acids are in such solutions diffusible and are stable above pH 6.2, that is just at the physiological reaction of the small intestine. Since neither trypsin nor the bacterial flora of the intestines decomposes these bile acids, it follows that the coupled bile acids as such may have an influence on the absorption of fatty acids. So it seemed necessary to examine some of the physico-chemical properties of such solutions. On examining the relationship between the respective concentrations of fatty acids and bile acids, it was found that in very dilute solutions perfect clearness could be obtained. Increasing concentration of fatty acids decreases the clearness of the solution. Such solutions cannot be cleared up, even by a very great amount of the bile acids. It is suggested that in low concentrations the existing state is a molecularly dispersed system, whereas at high concentrations we have a polydispersed system. The suggestion is supported also by ultrafiltration and diffusion experiments; according to the latter, in small concentrations (0.06%) all the fatty acids are diffusible, whereas in higher concentration (0.25%) part of them does not diffuse. Also the precipitation experiments show that such solutions are colloidal, the particles possessing negative charges.—*F. Verzár.*

709. **WERENINOW, A., M. und T. WINOGRADOFF, und M. DIAKOW. Die Einwirkung der Infusorien auf die Verdauung der Wiederkäuer.** *Biochem. Zeitschr.* 226(4/6): 387-394. 1930.—Experiments were made on 4 rams. They were starved for 1 wk.; the absence of infusoria from the 1st stomach was ascertained; then for 16 days the animals were fed sterilized food and the feces collected for 9 days. They were then artificially reinfected with infusoria, and, after the lapse of 10 days, the feces were again collected. While the difference in fecal content was not great, cellulose was better digested in the absence of infusoria.

710. **WILSON, ROBERT H. The rate of absorption of cystine from the gastrointestinal tract of the white rat.** *Jour. Biol. Chem.* 87(1): 175-180. 1930.—The rate of absorption of cystine, fed as the Na salt, from the gastrointestinal tract of the rat has been determined. The absorption is at the rate of 30.5 mgm. of cystine per 100 gm. of body weight per hr., a value lower than that of any other amino acid which has been reported. When fed as the hydrochloride, it is absorbed still more slowly, which may be due to decreased solubility of the cystine.—*Author's summary.*

711. **WINOGRADOW, M., T. WINOGRADOWA-FEDOROWA, und A. WERENINOW. Zur Frage nach der Einwirkung der Panseninfusorien auf die Verdauung der Wiederkäuer.** *Zentralbl. Bakt. II. Abt.* 81(8/14): 230-244. 1930.—The average of 2 test periods shows that dry material is about 3.4% less digested in the sterile sheep. This is confirmed by the colorimetric data (3.9%). Cellulose was about 12.8% less digested in the sterile sheep, but N about 4.5% better digested than in the normal sheep. As for the single experimental

period, in the first half there is an especially large negative difference, balanced in large measure in the second half and not beyond the limits of accuracy of the method. It is worthy of mention that the amount of the digestible energy in the 2nd half is the same in the sterile sheep as in the normal. The lowering of the digestibility of the food in the sterile sheep has manifested itself particularly in the 1st half, while in the 2nd half there is no important difference. On the basis of these results it can be stated that if the infusions exert a favorable action on the digestion of the cell tissue, this action cannot be important. We are not inclined to hold this conclusion as decisive since further tests are necessary with attention to the influence of the individuality of the animals.—*Authors' conclusions* (*transl. by G. T. Lewis*).

712. **GOLLWITZER-MEIER, KL. Anoxämie und Kreislauf.** *Pflüger's Arch. Ges. Physiol.* 220(3): 434-447. 1928.—A decrease in O partial pressure in inspired air from 160 to 120 mm. produces in the dog only a slight effect on the circulation. When the O pressure falls below 100 mm., significant circulatory phenomena always appear: increase in arterial pressure and increase in frequency, in output per beat and in min. vol. (determined by Fick's method). Notwithstanding the increased minute-volume, the venous pressure does not sink but increases slightly, apparently as a result of increased venous return to the heart. With a decrease in arterial O tension below 40 mm., min.-vol. decreases, usually with a simultaneous increase in frequency and a considerable increase in venous pressure; this is a sign of cardiac insufficiency. It is assumed that circulatory regulation is effected by central anoxemia. Changes in pH in the vasomotor center furnish an important stimulus for circulatory regulation.—*K. Gollwitzer-Meier* (*transl. by D. B. Dill*).

713. **GROLLMAN, ARTHUR. Physiological variations in the cardiac output of man. IX. The effect of breathing carbon dioxide, and of voluntary forced ventilation on the cardiac output of man.** *Amer. Jour. Physiol.* 94 (2): 287-299. 1930.—In 19 experiments on 4 subjects it was found that CO_2 did not affect the circulatory system of normal man until it reached a concentration of about 6% in the inspired air. Higher concentrations caused an increase in the pulse rate, blood pressure, and cardiac output. Forced voluntary ventilation of atmospheric air also caused a moderate increase in the circulatory rate. When CO_2 was added to the inspired air, to avoid any change in the alveolar tension of this gas, practically similar increases were observed. Since, in the last named experiments, only the mechanical effect of hyperventilation was present, the changes observed after natural breathing of CO_2-air mixtures or during forced respiration of air are also attributed to the mechanical aid which violent respiratory efforts exert on the circulation.

714. **GRÜNEBERG, FR., und A. VIETHEN. Die Wirkung von Kohlensäuregasgemischen auf die Atmung des gesunden und kranken Kindes.** *Jahrb. Kinderheilk.* 128(1/2): 65-82. 1 fig. 1930.—About 50 studies were made on the effect of mixtures of CO_2 with air or O on the respiratory center in 31 healthy children aged from 3 wks. to 14 yrs. The mixtures were exactly measured by the Franken apparatus. Mixtures of 0.5%-10% CO_2 with either air or O increased the aeration of the lungs, more decidedly if the CO_2 was given with interruptions than if given continuously. The amount of the increase in respiratory volume was exactly determined for each percentage of CO_2 from 0.5 to 10%; up to 4% the increase in volume was attained through deepened respiration; above that percentage a marked increase in the number of respirations per time unit was observed. Comparison of the action of CO_2 with that of lobelin showed that CO_2 was at least as effective as lobelin, in suitable cases more so; the action of CO_2 began earlier and was more intense. Atropine, cardiazol, coramin, strychnin and caffein showed no effect worthy of mention on respiration.

715. **HAZELHOFF, E. H., und HERMANN JORDAN. Die Regulierung der Atmung bei Insekten und Spinnen.** *Zeitschr. Wissensch. Biol. [Abt. C.] Zeitschr. Vergleich. Physiol.* 5(1): 179-190. 1 fig. 1927.—The observations were made chiefly on *Periplaneta americana*. The animals were fastened to a cork plate in a gas chamber and exposed to different temperatures and gas mixtures. At 28° C., the normal temp., the resting animal shows no movements of the almost completely closed spiracles. When in motion, living animals use only the first thoracic and abdominal pair. The others close completely for an instant at each expiration. Observations under water show that inspiration and expiration occur in all stigmata. Besides the known regulation of respiration, there is a regulation of diffusion. For example, animals die with all the stigmata dilated. When the temperature is increased the stigmata widen. 2 to 3% CO_2 opens the stigmata further. Increased ventilation (pumping movements) appears in the presence of 10 to 15% CO_2. Reduction of O to 5% often causes dyspnea. Experiments in which different gas mixtures are blown through a capillary tube show that each stigma is self-regulated peripherally. In 4 experiments it was shown that CO_2 is the physiological cause of the regulation of diffusion. In 10 kinds of insects and 5 kinds of spiders the same results were obtained. According to the literature, the normal closure of the stigmata is a protection against desiccation. Opening of the stigmata and with it diffusion ventilation is chiefly the result of local stimulation of the spiracles by CO_2.—*H. Kalmus* (*transl. by W. S. Root*).

716. **KRUSIC, IVAN. O tepelné polypnoi u ptáků. [A thermal polypnea in birds.]** *Biol. Spisy. Vysoké Školy Zvěrolékařské Brno* (*Publ. Biol. École Vétérinaires Brno*) 7: 97-102. 1928.—Birds, like many mammals, react to a high surrounding temp. by a thermal polypnea (accelerated respiratory movements). With birds this polypnea is central rather than reflex in origin. It occurs only as a result of a rise in body temp. During thermal polypnea respiratory movements are significantly modified in that rhythm and depth become very variable. Pigeons of all laboratory animals are most sensitive to high temp. while fowls are very resistant. In all the animals experimented upon respiratory movements of the throat were seen resembling those of amphibia and reptilia. The phase of recovery in birds in normal external temp. is accompanied by the same phenomena which Vacek has seen in certain mammals.—*Author's French summary* (*transl. by A. H. Turner*).

717. **SCHNEIDER, EDWARD C. Observations on holding the breath.** *Amer. Jour. Physiol.* 94(2): 464-470. 2 fig. 1930.—Among 318 American aviators (France, 1918-1919) the range of time for breath-holding was 29-128 sec. (mean time 67.8 ± 1.2 sec.). Among the army group of aviators 127 were given the official altitude classification examination. It appeared that the coefficient of correlation of breath-holding with the rate

at which the individual absorbs O was only -0.27 ± 0.06, and with the lowest degree of "O want" it was as small as -0.18 ± 0.06. Such low coefficients as these indicate that O is by no means the primary factor in bringing on the breaking-point in breath-holding. From these and other observations Schneider concludes that for the majority of men the length of time the breath can be held is determined more by psychological than by physiological factors. When, however, the length of time is determined by physiological factors, it is the composition of the blood, its alkaline reserve and its content of CO_2, which are of primary importance; while a lack of O is only a secondary cause in determining the length of the hold.

718. **SOMER, E. DE. Recherches sur les modifications que subit la respiration par des variations cardiaques. Relations cardio-respiratoires.** *Jour. Physiol. et Path. Gén.* 28(2): 311-320. 6 fig. 1930.—Definite arrest of the heart is a cause of respiratory acceleration, and should be included among the sources of abnormal effects in experimental work. An analogous condition is seen when the beat of the heart is weakened temporarily by such agents as intravenous injections of air or hydrochloric acid, stimulation of the vagus, collapse of the lung, and poisoning by chloroform or CO_2. These effects have been studied after section of both vagi, when the respiratory acceleration can no longer be observed, showing that the cardiac influence is not due to an anemia of the respiratory centre.—*W. R. Fearon.*

719. **UNDRITZ, W. The rhinoanemometer.** *Acta Oto-Laryngol.* 14(3/4): 513-524. 5 fig. 1930.—The rhinoanemometer is an apparatus for measuring objectively the quantity of air passing through the nasal cavity at inspiration and at expiration. The capacity of passage of the nose must be numbered among the other physiological tests characterizing the vitality of the organism. Researches concerning the capacity of passage of the nose, before and after being smeared with epinephrine, give a line on the vasomotor state of the organ.

720. **WINKLER, ALEXANDER. The regulation of respiration. The effects of hemorrhage and reinjection, and of the intravenous injection of sodium carbonate and sodium cyanide upon the response of the neuromuscular mechanism.** *Amer. Jour. Physiol.* 94(1): 224-234. 19 fig. 1930.—A series of experiments is described in which are studied the effects of hemorrhage, reinjection, and the injection of Na carbonate and Na cyanide upon the amplitude of contraction of the sartorius muscle of the dog. Both submaximal and supramaximal stimulation of the motor nerve and of the muscle were employed. The simultaneous responses to motor nerve and to direct muscular stimulation in general showed similar variations. Hemorrhage, if large enough, was found to produce a decrease in amplitude, reinjection an increase, the effect being the same whether submaximal or supramaximal stimuli were used. Na carbonate when injected in large quantities was found to produce an increase in the response to submaximal stimuli. Smaller quantities were without effect. The effect of carbonate on the response to supramaximal stimuli was inconstant and, in general, not significant. Moderate injection of cyanide produced an increase in the response to submaximal stimuli, sometimes followed by a decrease. Cyanide in larger quantities produced a decrease in the response to supramaximal stimuli. The effect of lesser quantities was uncertain. Some correlation between changes in pulmonary ventilation and those in muscular activity after cyanide was observed; such a correlation was not found with the other procedures. The relation of these experiments to the previous work of Glazer and Winkler was discussed. The conclusion was reached that the previously studied increase of the reflex response after hemorrhage and decrease after reinjection were probably wholly central in origin; the reflex increase after carbonate probably both central and peripheral, but mainly central; and the reflex increase after cyanide certainly peripheral in part with possibly a central component as well.—*Author's summary.*

721. **WINKLER, ALFONS. Experimentelle Beiträge zur Frage nach Charakter, Art der Akzentuation und Entstehung der Atemgeräusche über Kavernen.** *Wien. Arch. Inn. Med.* 15(3): 463-486. 1928.—From a study of the sounds produced by various alterations and various ways of blowing into a rubber model made of balls and tubes imitating the bronchial tree, conclusions are drawn concerning the pulmonary sounds. For the production of such sounds, a relatively strong stream of air is necessary. Cavities modify the sounds in various ways. Open cavities with elastic walls control the speed and strength of the air current. The air entering the cavity hits the opposite wall and causes vibration, which is regular and has a resonating effect if the wall is smooth inside, of greater amplitude if rough. Open cavities with non-elastic walls do not affect the volume of air passing. The basic respiratory sounds arise in the bronchioles which are connected to cavities, depend on the speed and strength of the air current, and are due partly to direct air currents and partly to vortices at branches. Elastic walls strengthen the sounds. If the opening into respiratory cavities is narrowed, the air current is increased and loud sounds result. A cavity which is not in use can affect the sound as the air crosses its opening. The vibration of the air started by the vocal cords diminishes towards the periphery of the bronchial tree. During expiration the glottis is narrower than at inspiration; the vibration of the air column is thus stronger at expiration. This effect of the glottis depends on its width and the force of respiration. The glottis can act on open but non-respiratory cavities and evoke typical sounds, which are accentuated at expiration. Closed cavities with fixed walls do not participate in the respiratory sounds. The typical cavity sound is loud and deep and of an amphoric character with high metallic overtones. Study of the rubber model shows that the classic cavity sound is produced only by large, open, elastic cavities, with smooth walls, and taking an active part in respiration. The pulmonary sounds are composed primarily of a multitude of single vibrations. The question of transmission of the sounds from various depths of the chest through normal and thickened lung tissue is discussed at length. Only the deeper sounds get through normal air-filled tissue; the higher vibrations are filtered out, the more completely the higher they are. Closed cavities not involved in the respiratory stream can participate in the sounds through being set in vibration by adjacent active tissue; their sound is amphoric. Otherwise, closed cavities are not detectable. The classic sound of open cavities can be heard at the chest wall only when a multiplicity of conditions is fulfilled, but as these conditions also determine the audibility and accentuation of expiration, the classic sound is associated with prolonged and accentuated expiration. This accentuation of cavity sounds is dependent on the glottis and is more marked the more central the cavities, less marked, the more peripheral they are. Conditions can be arranged in which the accentuation occurs on inspiration. The foregoing are only a few of the points made in the paper.—*L. H. Hyman.*

722. **WINTERSTEIN, HANS. Vorrichtung zur künstlichen Atmung unter physiologischen Bedingungen.** *Pflüger's Arch. Ges. Physiol.* 222(3): 409-410. 1929.—The animal is placed in a closed chamber through which only the head protrudes through an air tight rubber collar. A pump produces rhythmically a negative pressure by which physiological inspiration takes place. Expiration follows the return of air to the chamber.—*H. Winterstein (transl. by D. A. McGinty).*

723. **WINTERSTEIN, HANS. Kohlensaüre und Atmungsregulation.** *Pflüger's Arch. Ges. Physiol.* 222(3): 4f1-414. 1 fig. 1929.—With direct introduction of CO_2 into the blood stream, the increase of respiration corresponds fully to the shifting of reaction occasioned by other acids. The statement of Buytendijk that acid injection brings about no hyperventilation and that the blood becomes alkaline during reflex respiratory inhibition is erroneous and obviously due to mistakes in the method.—*H. Winterstein (transl. by D. A. McGinty).*

724. **AKEHI, T. Internal secretion of the pancreas and the female genital function. Part I. Histological investigation of the pancreas in pregnancy and puerperium, especially the Langerhans's islands.** *Japanese Jour. Obstetr. & Gynecol.* 13(4): 427-432. 7 fig. 1930.—The subject was studied in an unspecified number of rabbits. Individual experiments are not detailed, but the following conclusions are drawn: The Islands of Langerhans are gradually hypertrophied and proliferated in pregnancy, and a number of newly generated Islands appear. Such phenomena become more marked as pregnancy approaches term. During parturition, the Islands rapidly become atrophied and decrease in number. On the 1st and 2nd days of puerperium the condition of the Islands falls below that of the non-pregnant. The normal condition returns approximately on the 4th day of puerperium. The β cells of the Islands are affected most acutely by pregnancy and puerperium, and the other types show no marked change.

725. **ALLAN, H., F. DICKENS, and E. C. DODDS. Observations on the standardization of the water-soluble, oestrus-producing hormone.** *Jour. Physiol.* 68(4): 348-362. 1930.—The problems of evaluation of vaginal smears, of methods of administration of the oestrus-producing hormone, and of variations in response have been considered. The relationship between the dose of hormone administered and the percentage of rats showing positive oestrus response is shown by curves. By means of these, unknown preparations may be compared with a standard. It was found that injection of single doses gave much less response even though the total number of units was the same as that given in divided doses. If the single dose was administered in oil the response was greater. Oral administration, even in divided doses, was very inefficient. The application of these experiments to the question of standardization is discussed.—*A. M. Woodruff.*

726. **ANSELMINO, KARL JULIUS, und FRIEDRICH HOFFMANN. Nachweis einer glykogenvermindernden Substanz (Schilddrüsenhormon) im Blute von Schwangeren.** *Arch. Gynäkol.* 143(2): 310-318. 1930.—Serum from pregnant women (14), from 2 directly after delivery and during the puerperium, from 2 fetuses, and from an unstated number of nonpregnant women, was injected subcutaneously into ♂ mice (0.5 cc. 5 times at 12-hr. intervals; mice killed on the 4th day). The glycogen content was decreased beginning with serum from the 2nd mo. of pregnancy and continued to decrease until the 2nd day of the puerperium when it began to increase, being almost normal on the 8th day. Fetal blood contained far less of the glycogen-decreasing substance than did the maternal. At the end of pregnancy 2.5 cc. serum produced a 75% decrease in liver glycogen in the mouse. Similar investigations with thyroxin showed that 40-50 γ thyroxin had the same action as 2.5 cc. serum.

727. **ARLOING, FERNAND, A. JOSSERAND, et J. CHARACHON. Cortico-surrénale et cancer expérimental.** *Bull. Acad. Méd. [Paris]* 103(8): 211-214. 1930.—In the course of 1½ yrs. of experiments not detailed, the authors found that the suprarenal cortex of a rabbit injected with substance of white mouse tumor became endowed with the property of retarding or arresting the growth of such tumors. Grafts or glycerinated extracts of such suprarenals in tumor-bearing mice were active if the suprarenal were taken without delay; if, however, the rabbits were not killed promptly, the suprarenal was either ineffective or even promoted the tumor growth. After such delay, the suprarenal cortex became yellow, tripled in thickness, and showed a zone in which there was an enormous development of spongiocytes. These phenomena the authors link up with the discoveries of Sokoloff with regard to the suprarenal cortex of cancerous mice.

Physiol.* 278 (2): 383-390. 4 fig. 1930.—The thymus hormone used was a dry powder prepared from the calf's thymus by the Institute of Experimental Endocrinology in Moscow. It was given for periods up to 4 mos. to 30 white ♂ rats aged from 3 wks. to 6 mos. The dosage was for some rats 0.01-0.08 [unit ?] and for others 0.2-0.6. The lower dosage produced no difference in growth, weight or sexual organs between treated animals and controls, but treated animals were sluggish and depressed so long as thymus was administered. The higher dosage produced no difference in growth, but did cause general disturbance of metabolism, slightly lower weight than that of the controls, general sluggishness, nervous depression, and, in immature rats, delayed sexual development, in the adults, hastened degeneration of the seminiferous tubules. On the other hand, the rats receiving high thymus dosage seemed to show increased resistance to infection and more rapid and cleaner healing of wounds. Details of experiments are not given.

loghi di surreni in conigli. [Heterologous suprarenal implants in rabbits.] *Policlinico [Sez. Pratica]* 37(28): 1017-1019. 1930.—In an unspecified number of rabbits triturated suprarenal gland tissue was implanted under the skin of the back, 2-8 implants per animal being made at intervals of 7-14 days in doses of 1.5-20-30 cgm. The rabbits were killed 1-6½ mos. after the 1st operation; no histologic changes were found in arteries or veins.

733. **BELAWENETZ, S. Über die Wirkung der Thyreokrinfütterung auf die Hoden der weissen Ratten.** *Anat. Anzeiger* 65(9/10): 155-161. 5 fig. 1928.—Feeding "thyreokrin" ("hormone of the thyroid") to white rats aged 4 weeks to 8 mos., in doses of 0.005 to 0.05 gm., caused a degeneration of the testicles in both mature and immature subjects, most severe in the latter. In spite of increasing doses the degeneration was followed by a regeneration which appeared earliest in the adults (25-35 days) and later in the immature animals (10 weeks). In the beginning of this regeneration the persisting living spermatogonia, not the Sertoli cells, participated. Animals receiving "thyreokrin" lose their procreative faculty through a failure of the functional capacity of the spermatozoa since coitus was observed. The observation period was too short to determine the duration of the impotence.—*J. B. Youmans.*

740. **BUTENANDT, ADOLF. Über physikalische und chemische Eigenschaften des krystallisierten Follikelhormons. Untersuchungen über das weibliche Sexualhormon. (5.)** *Hoppe-Seyler's Zeitschr. Physiol. Chem.* 191 (3/4): 140-156. 1 pl., 4 fig. 1930.—The pure follicular hormone, characterized by melting point, crystalline form, solubility, optical rotation, ultraviolet absorption spectrum and physiological action, has, according to previous determinations, as its probable formula $C_{18}H_{22}O_2$; this formula needed further confirmation, since the homologous formula $C_{17}H_{20}O_2$ appeared according to former researches not completely excluded, though much less probable. The relations of the O atoms could be verified. One is present as an easily esterifiable hydroxyl group, as could be shown by the preparation of acetyl and benzoyl derivatives; the other O atom is in a carbonyl group, which gives a test with ketone reagents. The hormone therefore has the structure of a hydroxyketone; it is probable that the transformation of the neutral substance into an alkali-soluble form (a reaction that corresponds to that of a lactone) is to be explained by a ready transformation of the carbonyl group into an enol group. The molecule probably contains 3 double bonds. These are saturated by intensive hydrogenation with simultaneous reduction of the keto group. The hydrocarbon $C_{18}H_{30}$ is the foundation for the completely hydrogenated hormone $C_{18}H_{32}O$. It contains 8 fewer H atoms than a saturated paraffin, a fact that can be explained by the presence of either an aromatic nucleus or of 4 hydrogenated rings in the molecule.—*Author's summary (transl. by G. L. Kelly).*

741. **CAMERON, A. T., and F. D. WHITE. Preliminary note on an attempt to concentrate the active principle of the adrenal cortex.** *Trans. Roy. Soc. Canada Sect. V.* 22(2): 145-149. 1928.—An active principle of the adrenal cortex, capable of accelerating growth when fed to young white rats, passes into solution during hydrolysis with N/10 HCl. The action of this compound is antagonised, at least in part, by adrenin. Such antagonism is overcome by simple oxidation. It is doubtful whether ethyl alcohol fractionation affords a real method of concentration, the apparent results being probably due to the adrenin fractionation produced. Methyl alcohol extraction permits concentration. An effective method of removing adrenin without destruction of the active principle of the cortex must next be found. Adrenin, fed to young rats for a period of 18 days or longer, produces definite toxic effect, including marked inhibition of growth.—*From authors' conclusions.*

742. **CANNON, W. B., and Z. M. BACQ (with the assistance of R. M. MOORE). Studies on the conditions of activity in endocrine organs. XXVI. A hormone produced by sympathetic action on smooth muscle.** *Amer. Jour. Physiol.* 96(2): 392-412. 1931.—In a cat with heart denervated, adrenals and liver excluded from action and spinal cord severed in the mid-thoracic region (so as to permit, without anesthesia, painless operations in the hind part), stimulation of the sympathetic supply to the smooth muscle of the tail hairs (and of the blood vessels of the region) causes, for about 2 min., a gradual increase of blood pressure, a gradual increase of heart rate and a gradual increase of salivary secretion. The time relations of the increase and the slow return to the former state are, in each instance, similar to those reported for the denervated heart alone, as a consequence of emotional excitement. If the blood flow into and from the legs and tail is hindered, the phenomenon is much reduced or is delayed until the flow is restored. Since the only tissue known to be affected by sympathetic stimulation at the base of the tail or on the mesenteric arteries is smooth muscle, since the only connection be-

tween the hind part of the animal and the responding denervated organs in the fore part is the blood stream, and since interfering with the stream in the region where smooth muscle is stimulated either markedly depresses or abolishes the response, it is inferred that a substance is given off from smooth muscle into the blood, that it is carried effectively by the blood to distant organs, and that it influences those organs as sympathetic impulses would influence them. Because the properties just mentioned are those of a hormone the authors regard the substance given off by smooth muscle, when affected by sympathetic impulses, as a hormone. The substance arises not only from pilomotor muscles, but also from the smooth muscle of the intestine, and the bladder and uterus. Because the substance is derived from structures under sympathetic control, when they are influenced by sympathetic impulses, they suggest that it be called sympathin. Sympathin is given off from the smooth muscle of the tail and can increase the heart rate after ergotamine has prevented sympathetic impulses from causing erection of the tail hairs. The bearing of these observations on those of Loewi and others on the humoral transmission of nerve impulses, the support which the observations bring to some early views of Elliott, and the possible relations of sympathin and adrenin, are considered in the discussion.—*Authors' summary.*

Le secrezioni pancreatiche dopo l'iniezione di peptone.** [The pancreatic secretions. I. In the normal condition. II. After injection of histamine. III. After injection of peptone.] *Policlinico [Sez. Med.]* 37(2): 90-96; (6): 289-297; (7): 344-352. 1930.—I. In 6 normal dogs the pancreatic secretions were determined in the blood serum and in the urine. Insulin production was estimated indirectly from the glycemic curve. No uniformity in pancreatic secretion was observed nor was there any distinct parallelism between the endocrine secretion (insulin) and the exocrine (digestive ferments). Similar results were obtained on a dog with a pancreatic fistula. II. 5 normal dogs and a pancreatic fistula dog were subcutaneously injected with histamine. The blood sugar increased sharply and progressively. The ferments were slightly augmented. In the pancreatic fistula dog, histamine increased the volume of pancreatic juice from 4 cem. to 12.3 without a corresponding increase in the enzymatic activity of the ferments; there was no parallelism between the activity of the 3 ferments (diastase, lipase and trypsin). No relation was observed between the endocrine secretion and the ferments after histamine. III. Peptone was subcutaneously injected into 4 normal dogs and intravenously into 1; subcutaneously also into a pancreatic fistula dog. A marked and constant rise in blood sugar resulted. The pancreatic ferments were slightly and irregularly affected. Peptone apparently does not stimulate the pancreatic acini. The trend of the 3 series of experiments indicates the mutual independence of the endocrine and exocrine pancreatic secretions, and of the various constituents of the pancreatic juice.

Sperim.* 5(3): 340-342. 1930.—Extracts of testicle and ovary of lower vertebrates administered either per os or parenterally have a double action, a stimulating one on the sexual functions, and an inhibiting one on the thyroid (these actions were tested on human hyperthyroids).—*M. Comel.*

747. **CLAUBERG, CARL. Der biologische Test für das Corpus luteum Hormon.** *Klin. Wochenschr.* 9(43): 2004-2005. 3 fig. 1930.—In tests upon baby rabbits weighing less than 600 gm. the same quantity of corpus luteum hormone was required to produce proliferation of the cells lining the uterus as with larger animals. Doses of 10 mouse units were given daily for 8 days and produced definite proliferation of the uterine cells. Animals were killed daily and it was found that the normal appearance was exhibited on the 6th day after discontinuing injections. A rabbit unit (K. E.) is proposed which is the quantity of corpus luteum hormone producing a definite change in the uterine cells persisting for 5 days. The desired response is shown by illustrations in the original article.—*C. Clauberg (transl. by J. C. Munch).*

748. **CLAUS, PEARL E. Separation of anterior-lobe substances and study of their individual effects.** *Physiol. Zool.* 4(1): 36-55. 6 pl. 1931.—The technical procedure for separating 2 substances of the anterior lobe of the pituitary is described: one, a crystalline product which is the follicular stimulating factor; the 2nd, a substance which causes luteinization of the follicles. The method consists of extracting the anterior-lobe substance with alcohol containing 2% HCl, purification by use of acetone, ether, and absolute alcohol, and crystallization from glacial acetic acid. An aqueous extract of the crystals causes precocious sexual maturity in immature female and male mice, and stimulates increased follicular development in adult female rats. The crystals in question have not only been obtained from anterior-lobe tissue, but also from the urine of pregnant women, the epididymis of the bull, fish sperm, thyroid gland, and adrenal cortex. Whatever the source, the same physiological properties are manifested. This widespread occurrence opens up the question of whether we may not be dealing with a substance more general in nature than a hormone as ordinarily conceived. This can only be answered through further experiment. With the exception of the crystals, the only other active fraction obtained from the anterior pituitary by the procedure described was the luteinizing substance. This fraction causes the formation of atretic corpora lutea in the ovary, but does not cause precocious sexual maturity. It also stimulates placentomata formation, whereas the crystals do not.—*Author (courtesy Wistar Bibl. Serv.).*

749. **COGNETTI de MARTIIS, LUIGI. Sulla ormoni sessuali e sulla derivazione germinale di quello testicolare.** [Sexual hormones and their derivation from testicular cells.] *Bull. Mus. Zool. e Anat. Comp. Univ. Genova* 9(32): 1-21. 1929.—Cattaneo (1913) first indicated the modifying action of the hormones of various organs on the primordial cells and their derivatives. This action is perhaps correlated with the modifications of various organs. The author conceives a germ-cell origin of the male sex hormones; the phagocytic resorption of sex cells by the Sertoli cells supports this idea. The hormones may originate (a) from the metabolism of the primordial germ cells as they develop and multiply, (b) from phagocytic Sertolian metabolism. The *a* products may be absorbed by the Sertoli cells, but may also function in the resorption of primary spermatogonia which degenerate abundantly in mammalian testes during spermatogenesis. The *b* products would aid in puberty and would stimulate the completion of secondary sexual characters which have been initiated by the stimulating action of other products. A complementary metabolic action of the interstitial cell products on *a* and *b* is not excluded.—*L. Cognetti de Martiis (transl. by R. A. Muttkowski).*

750. **COLE, H. H., and G. H. HART. Sex hormones in the blood serum of mares. II. The sera of mares from**

the 222nd day of pregnancy to the first heat period postpartum. *Amer. Jour. Physiol.* 94(3): 597-603. 2 fig. 1930.—Serum was collected from mares between the 222nd day of pregnancy and the 1st heat period following parturition to study its effect upon the genital system of immature rats. The serum was found to produce an effect upon the genital system until about the time of parturition. A positive vaginal reaction, a weak uterine reaction, and an inhibiting effect upon the ovaries were regularly observed. No reaction was observed from serum taken after parturition.—*Authors' summary.*

751. COLOMBI, CAMILLO. L'azione dell'ormone ipofisario anteriore sul testicolo, con parficolare riguardo alle cellule interstiziali. [Action of the hormone of anterior hypophysis on the testicle, and especially on the interstitial cells.] *Boll. Soc. Ital. Biol. Sperim.* 5(5): 726-728. 1930.—Injections of urine of pregnant women were followed in mice by increase of the interstitial cells. —*M. Comel.*

752. COMEL, M. Azione e meccanismo d'azione di dosi eccessive di ergosterolo irradiato sull'insufficenza paratiroidea sperimentale. [Studies on the action of overdoses of irradiated ergosterol on experimental parathyroid insufficiency.] *Arch. Fisiol.* 29(1): 123-144. 1930.—When overdoses of irradiated ergosterol are administered to dogs during a period of time either immediately preceding parathyroidectomy, or following it, the appearance of functional symptoms of the parathyroid insufficiency is prevented, with the exception of a diminished resistance to infections. The latter may however be due as well to the ergosterism itself (intoxication by irradiated ergosterol). Although the administration of overdoses of irradiated ergosterol is followed by a rise in the blood Ca, the hypercalcemia does not persist, in the parathyroidectomised dogs. Hypocalcemia follows, but only a little increase in the amount of serum P is observed, the quotient Ca/P persisting accordingly at values above 1 and nearly normal. The survival of the parathyroidectomised dogs is prolonged indefinitely in those cases (the majority) where infective processes did not occur. After a variable period the serum Ca and P content reverts to normal values. The action of the irradiated ergosterol is explained by a substitutive influence of the function of the parathyroid glands upon tissues, their irritability and permeability. The final return to the norm and indefinite survival are explained by an intervention of aberrant parathyroid tissue, which has undergone hypertrophy in the meantime.—*M. Comel.*

753. COMEL, M. Studi sulla sindrome paratireopriva in cani trattati con stronzio. [Studies on parathyroid deficiency in dogs treated with strontium.] *Arch. Fisiol.* 29(2): 159-180. 1930.—The action of Sr on parathyroid deficiency is demonstrated only if treatment is sufficiently intense as to cause intoxication by Sr. Tetany is prevented or inhibited if already developed. If treatment with Ca "exosiossipropionato" is associated with the treatment with Sr "exosiossipropionato" the Ca cannot substitute for Sr, the action of which is more effective. The other symptoms of parathyroid deficiency, serological as well as functional, are not affected by Sr; yet the survival of the animals is prolonged. The Sr exerts its action by affecting the nervous system, acting probably on the cerebral and cerebellar cortex as well as on the spinal centers. An action on peripheral nerves as well as an action on muscle is possible. In normal dogs treated with Sr, modifications of the parathyroid glands were observed. No direct relation between calcemia and tetany existed in the operated and treated dogs, whereas a relation existed between tetany and Ca/P ratio. It is probable that two distinct periods of parathyroid deficiency exist, the first of acute, the following of subacute or chronic deficiency.—*M. Comel.*

754. COMEL, MARCELLO. Ricerche sulla sindrome paratireopriva. III. Suo decorso negli animali sottoposti a trattamento con stronzio e calcio. [Sr and Ca effect in parathyroid insufficiency.] *Boll. Soc. Ital. Biol. Sperim.* 5(5): 729-732. 1930.—Tetany, although it is rendered milder following treatment with Ca "exosiossipropionato," is completely inhibited only if treatment with Sr "exosiossipropionato" is given. This treatment is efficient only when intoxication by Sr is reached. Tetany no longer appeared, but hypocalcemia, hyperphosphatemia and the other symptoms persisted.—*M. Comel.*

755. COMEL, MARCELLO. Studi sulla sindrome paratireopriva. IV. L'azione su di essa dell'ergosterolo irradiato somministrato in dosi eccessive e il suo meccanismo. [Effects of overdosage of irradiated ergosterol on parathyroid deficiency.] *Boll. Soc. Ital. Biol. Sperim.* 5(5): 732-734. 1930.—When overdosage of irradiated ergosterol (subcutaneous) has preceded, or immediately followed parathyroidectomy, no tetany ensues, although hypocalcemia is developed. P rises in serum, but never so conspicuously as in nontreated parathyroid deficiency. In a later stage the Ca and P values become normal in serum, while no tetany is developed. A few animals died from septic infections of the skin; a greater number survived indefinitely. The author attributes indefinite survival to a progressive hypertrophy of aberrant parathyroid tissue, whereas ergosterol aids the animal to sustain the first stage of acute deficiency. —*M. Comel.*

756. COMEL, MARCELLO. Modificazioni delle paratiroidi nello stronziamismo sperimentale. [Modifications of parathyroid glands following experimental strontianism.] *Boll. Soc. Ital. Biol. Sperim.* 5(5): 735-737. 1930.—Following experimental poisoning with Sr "exosiossipropionato" the parathyroid glands grow in size and show hyperplasia and hyperemia. To such changes a probable hyperfunction is to be attributed. It is explained by an endocrine protective function of parathyroid against Sr poisoning through its Ca regulating or through its detoxicating activity.—*M. Comel.*

757. EHRHARDT, KARL. Eine artefizielle Schwangerschaftsreaktion (A. Z. R.) bei der nichtschwangeren Frau. Beitrag zum Verhalten des Hypophysenvorderlappenhormons im nichtgraviden Organismus und zur Frage der therapeutischen Wertigkeit von Prähormon verglichen mit derjenigen von Schwangerenblut. *Arch. Gynäkol.* 143(2): 446-458. 1930.—In 4 cases of amenorrhea and uterine hypoplasia a blood transfusion from a pregnant donor was made, 3500-7000 mouse units being given. After the transfusion, reaction II-III was present in the blood from 2 to 12 hrs. Later samples showed reaction I or were negative. During the first 24 hrs. the urine gave a positive reaction II-III, the hormone appearing in the urine in about 10 min. and remaining 12-24 hrs.

758. EULER, ULF von. Studien über die Beeinflussung der Gewebsoxydation durch Adrenalin und Insulin mit besonderer Berücksichtigung der Bedeutung der Innervation. *Skand. Arch. Physiol.* 59(3/4): 123-200. 8 fig. 1930.—The influence of epinephrine on muscle respiration was investigated by the manometric respirometer method of Barcroft-Warburg. Epinephrine increases the utilization of O by intact as well as finely divided muscle in concentrations of 10^{-6} to 10^{-14} in agreement with the earlier findings of Ahlgren with the methylene blue method. The increase of oxidation appears only with O concentrations of 2 to 10%, under the given experimental conditions, that is only with a suboptimal supply of O. Epinephrine increases the utilization of O in washed muscle only after addition of glycerophosphates and hexosephosphates among a series of substances investigated. After the addition of lactic acid, epinephrine produces inhibition. As it was first shown that the effect does not occur after denervation of the muscle, it could be shown that section of the rami communicantes supplying the muscle checked it. Section of the motor nerves did not prevent this action. The antagonism of epinephrine and ergotamine could also be shown in respect to muscle respiration. The utilization of O in the system: glycerophosphate-glycerophosphoric acid-redoxase solution (from the white matter of the brain) is not influenced by epinephrine. It

does not increase the utilization of O nor the methylene blue reduction of erythrocytes and leucocytes, neither does it do so in the presence of glycerophosphates or hexosephosphates. A summary of the findings concerning the influence upon tissue oxidation of insulin yields the following: The experiments of Ahlgren with methylene blue, as well as those with the microrespirometer, demonstrating the effect of insulin in increasing the oxidation in the presence of glucose were confirmed in respirometer experiments, as well as by other methods. The negative findings with the same method which have several times been published can most likely be traced to unfavorable experimental conditions. It was shown that the effect of insulin on muscle occurred first with suboptimal O, as exhibited in the present valid experimental conditions of O pressures of from 2 to about 10% O in N. In O pressures of more than 10% the effect of insulin on finely divided muscle could not be shown. As the negative findings in this respect were obtained chiefly with the Warburg method and optimal O supply, they are of no value in proving the absence of insulin effect. The insulin-glucose action gave the same results on intact muscle. The insulin effect could be shown still better on brain tissue. The oxidation increasing effect of insulin is not, as formerly believed, limited to glucose; it is possible also to obtain the same effect with glycerol. The possibility of a transformation of glycerol into glucose by the tissue received no support. The oxidation of glycerol in the presence of insulin appears in many respects to suggest points of comparison with the oxidation of glucose (weakening of the effect after keeping the muscle for 2 hrs. at room temperature, antagonism toward epinephrine). The cessation of action of insulin previously found when muscle is utilized which has been kept for about 2 hrs. at room temperature, could be confirmed. These experiments showed that with freshly cooked muscle juice, as well as with cozymase preparations, the effect of insulin could be reactivated with glucose as well as with glycerol, whereby the first point as to the nature of glykomutin (Ahlgren) has been established. The relations between glykomutin and cozymase are briefly discussed. When muscle is deprived of sympathetic innervation at various times previously (2 days to 2 mos.) the effect of insulin can no longer be obtained. However, motor denervation does not interfere with insulin action. An insulin action could not be proved on erythrocytes or leucocytes. The antagonism of insulin-epinephrine in the presence of glucose could be confirmed, and it could be shown that this antagonism occurs also in the presence of glycerol.—*Author's summary (transl. by G. Bachmann).*

759. FEE, A. R., G. F. MARRIAN, and A. S. PARKES. The significance of the occurrence of oestrin in male urine. *Jour. Physiol.* 67(4): 377-382. 1929.—Small amounts of oestrin can be obtained from male urine. After large doses of oestrin have been added to the circulation in the heart-lung-kidney preparation, small amounts can subsequently be detected in the urine. The hormone disappears very rapidly from the blood in the heart-lung preparation. Disappearance is not due to absorption by the tissues of the lungs and heart but probably results from oxidation as the blood circulates through the lungs. Owing to the fact that large amounts of oestrin can be found in the urine of pregnant women, these results suggest that large amounts of the hormone must be produced during pregnancy.—*C. W. Bellerby.*

760. FERRARI, RODOLFO. Influenza della tiroide sull'edema da perfusione con soluzioni saline. [Action of thyroid gland on the edema from perfusion with salt solutions.] *Arch. Fisiol.* 29(2): 191-202. 1930; also in *Boll. Soc. Ital. Biol. Sperim.* 5(3): 414-416. 1930.—The edema caused in the ear or in the hind leg of rabbits by perfusion with oxygenated Ringer-Locke's solution has a practically constant intensity. After thyroidectomy the edema produced in the same conditions is noticeably greater. The presence of small amounts of thyroxin in the perfusing fluid caused the edema of normal animals to decrease in a remarkable manner. The thyroid gland exerts an action preventing edema; such action is shown to exist also in tissues removed from the organism.—*M. Comel.*

761. FLUHMANN, C. FREDERIC. The induction of the pseudo-pregnancy vaginal reaction in spayed mice by the injection of human blood. *Amer. Jour. Physiol.* 95(2): 422-426. 1 fig. 1930.—The test has been used to examine the blood of over 70 patients. A mucification of the vaginal mucosa of spayed mice has been produced by the injection of blood serum from patients in whom it is known there is a histologic corpus luteum, namely, during pregnancy, early in the puerperium, during the premenstrual stage, and accompanying a corpus luteum cyst. However, since it has also resulted from the injection of blood from men, from 1 woman following a bilateral oöphorectomy and from 4 women past the climacteric, it does not seem justifiable to consider it as a reliable test for the presence of progestin in the blood.

Gén.* 28(2): 342-356. 11 fig. 1930.—In thyro-parathyroidectomised dogs the blood Ca falls rapidly to half the normal value or less. At the same time, the vaso-motor and secreto-motor activities of the splanchnic becomes weaker. With a few animals this loss of nerve excitability is only slight. With all animals examined intravenous injection of 4% $CaCl_2$ restored completely the activity of the nerves. This is ascribed to the rise in blood Ca, which in one experiment was increased from 7 mgm. per 100 cc. to 16.5 mgm. per 100 cc., as the result of injecting 2 gm. of $CaCl_2$.—*W. R. Fearon.*

766. GLEY, E. et EDW. CZARNECKI. Contribution à l'étude des interrelations humorales. III. Nouvelles recherches sur les prétendues relations entre la thyroïde et les surrénales. *Jour. Physiol. et Path. Gén.* 28(2): 357-360. 1930.—The alleged dependence of the adrenal apparatus on the thyro-parathyroid apparatus is explained by the effects of hypocalcemia following parathyroidectomy. Hypocalcemia causes a lowered splanchnic activity (cf. preceding abstract), which has been mistaken for an adrenal deficiency. When this is recognised it can be shown that no hypofunction of the adrenals follows suppression of the thyroid apparatus.—*W. R. Fearon.*

767. GLEY, PIERRE. Sur la préparation de l'hormone du corps jaune. [Methods of preparation of the corpus luteum hormone.] *Jour. Physiol. et Pathol. Gén.* 27(3): 528-540. 1929.

768. GOLDSTEIN, BORIS. Zur Funktionsprüfung des Pankreas. *Arch. Verdauungs-Krankh.* 48(5/6): 304-317. 1930.—The results obtained (in 11 cases with achylia gastrica, 6 with normal acidity and 3 with hyper-acidity) show that the secretory processes in the pancreas are independent of each other. Secretin stimulates the secre-

tion, the vagus the ferment production; the sympathetic system controls both processes. The secretion after acid stimulation is most likely a mixed action of secretin and sympathetic stimulation. In achylia gastrica there is an increased concentration of diastase in duodenal content and especially in the blood. A high ferment concentration in achylia gastrica is not a sign of hyperfunction of the pancreas. It is the result of a change in the factors affecting the gland—the absence of secretin stimulation and probably also the absence of sympathetic stimulation. Insufficiency of pancreatic activity is characterized by a marked decrease of the diastase concentration in the duodenal content.—*K. Reuterskiold.*

769. **GRAFF-PANCSOVA, E. Über den Mechanismus der Thymophysinwirkung, zugleich ein Beitrag zur Verstärkung der Hormonwirkung.** *Arch. Exp. Pathol. u. Pharmakol.* 136(3/4): 158-171. 3 fig. 1928.—Dogs with a bladder fistula were used for these experiments. They received no water nor food for several hrs., then were given by stomach tube 200 cc. water and the urine output for the next 2 hrs. measured. Subsequently they received 200 cc. water plus 0.02 cc. hypophysis extract subcutaneously; 200 cc. water plus 0.5-1.0 cc. thymus extract; or 200 cc. water plus 0.02 hypophysis extract plus 0.5 cc. thymus extract. Thymus or hypophysis extract alone had little effect in lessening the amount of diuresis while the combination decreased it from 3 to 7 times. Novoprotein, Witte-peptone, and muscle extract, likewise, strengthened the anti-diuretic action of posterior pituitary hormone while extracts of mammary gland, placenta, parathyroid, and adrenal had practically no effect. It is concluded that the strengthening of the anti-diuretic action of the hypophysis is due to the protein or protein decomposition products rather than to the extract of any specific organ.—*P. E. Claus.*

770. **GRANT, MADELEINE P. The release of follicular colloid from the thyroid of Necturus maculosus following heteroplastic anterior-pituitary implants.** *Anat. Rec.* 46(3): 205-221. 3 pl. 1930.—Histological studies were made of the thyroid following implantations of the anterior lobe of the anuran pituitary into the peritoneal cavity of 10 mos. old *Necturus* larvae. Control cases showed thyroids with a histological picture characteristic of the inactive gland, with low cuboidal cells, possessing homogeneously staining cytoplasm. The follicular colloid stained strongly acid and appeared highly refractile. The 1st histological evidence of response of the thyroid to anterior-lobe implantation appeared within 12 hrs. and showed extreme vacuolization of the cytoplasm of the cells and intracellular droplets of colloid. From the study of a series of cases fixed at 24-, 48- and 72-hr. intervals, it was evident that the follicles progressively released the stored colloid. At the end of the 3rd day, the majority of the follicles were completely collapsed and empty. The morphological picture throughout these timed series was an abundant intracellular colloid content which first appeared in the form of large, discrete, refractile, colloid droplets and, in the later stages, as an "emulsion" of colloid in cytoplasm. Since the follicles showed progressive release of stored colloid and the correlated morphological pictures showed abundant intracellular colloid content, the thesis of transportation of stored colloid through the follicular cells of the *Necturus* thyroid is presented.—*Author (courtesy Wistar Bibl. Serv.).*

771. **GREENWOOD, A. W., and J. S. S. BLYTH. An experimental analysis of the plumage of the Brown Leghorn fowl.** *Proc. Roy. Soc. Edinburgh* 49(4): 313-355. 4 pl. 1929.—The influence of partial and complete thyroidectomy and the feeding of desiccated thyroid on the plumage of otherwise normal and castrated Brown Leghorn fowls was studied. Hypothyroidism results in a diminution in the amount of melanin and an extension of the red pigment in both sexes, and in a lack of barbule formation coincident with increased fringing. Hyperthyroidism in the ♂ leads to the opposite effect, viz., an increase in the melanin and barbules while the red pigment and fringing tend to disappear. In the ♀ the effect of thyroid feeding is slight. The hypothesis is advanced that the plumage typical of the ♂ is developed independently of the gonads but depends upon a certain level of thyroid activity while that of the female is controlled by the interaction of the thyroids and gonads. The ovaries stimulate the thyroids to greater activity. The plumage of young chicks of both sexes is similar to that of the adult female. This is ascribed to the yolk of the young chick which exercises an influence similar to, but less in degree than, that of the ovary from which it arises. Thyroidectomy was followed by a marked depression in growth rate, but did not affect the age of sexual maturity, the average weight of the eggs, the fertility of the animals, the fertility of the eggs, or the sex ratio of the chicks.—*J. A. Dye.*

772. **GUASSARDO, GUIDO. Variazioni del contenuto in Ca e K nel siero di sangue in seguito all'iniezione di determinati ormoni (ipofisina, tiroxina, paratiroidina, insulina, adrenalina). (Ricerche sperimentali.)** [Variations in blood serum Ca and K following injection of certain hormones.] *Riv. Clin. Pediatr.* 28(10): 841-855. 1930.—Stimulation of the sympathetic by injection of epinephrine or thyroxin produced in 3 dogs a reduction of serum Ca followed by a reduction of K; stimulation of the parasympathetic by parathyroidin, insulin or hypophysin produced a rise in K followed by a rise in Ca. A disturbance of the K: Ca ratio, however, inverted the action of the branches of the vegetative nervous system; thus, in presence of an excess of Ca, stimulation of the vagus did not inhibit but stimulated the heart.

773. **GÜNTZ, EDUARD. Schrumpfnebennieren mit Hodenatrophie. Zugleich ein Beitrag zu Wesen und Bedeutung der Zwischenzellen.** *Frankfurter Zeitschr. Path.* 40(3): 490-500. 1930.—A case of Addison's disease which displayed the clinical picture of a paratyphus was produced by cytotoxic atrophic adrenals. A high degree of atrophy of both testicles was also found in the 28-year-old male. Contrary to other atrophic conditions of the testicle the interstitial cells were much reduced. It is attempted to consider the 2 pathologies as a syndrome. The author concludes that a definite interrelationship, though not of clear and uniform character, exists between the 2 glands, and that only in primary endogenous disease of the adrenal cortex is testicular atrophy observed, as in the case in question. The testicular disease must be a result of the injury to the adrenal cortex and possibly the hypophysis (not microscopically examined) is concerned. Conclusions as to the importance of the interstitial cells can be drawn only in so far as it is evident that they constitute a passive organ of the endocrine system.—*Author's summary (transl. by C. S. Leonard).*

774. **HABERLANDT, L. Über ein Hormon der Herzbewegung. XIII. Mitteilung. Fortgesetzte Froschherzversuche mit dem Herzhormonpräparat.** *Zeitschr. Ges. Exp. Med.* 68(1/4): 185-195. 6 fig. 1929.—An extraordinarily active hormonal preparation has been made which has both a positive chronotropic and bathmotropic action on the ventricle of the isolated frog heart, in dilutions in Ringer's solution as high as 1: 100 million or even 1: 1000 million. The quiescent ventricle could also be started to beat in these dilutions. The refractory period is usually shortened by the substance, or is unaffected; rarely it is lengthened. Time is a factor in these latter effects. It is affirmed that the effects described are not due to epinephrine, histamine or K, as claimed by certain other experimenters.—*M. Dresbach.*

Physiol.* 225(2/3): 384-388. 4 fig. 1930.—The preparation of cardiac hormone in dilutions of 1: 1000 to 1: 50 promoted movements of isolated frog stomach and of guinea-pig and rat intestine, the effect persisting after atropinization.—*From author's summary (transl.).*

776. **HABERLANDT, L. Über ein Hormon der Herzbewegung. XVIII. Mitteilung. Versuche an Wirbellosen.**

Pflüger's Arch. Ges. Physiol. 225(4): 541-557. 10 fig. 1930.—These experiments were made on the hearts of snails. Isolated hearts of *Helix pomatia,* which had become motionless in Ringer's fluid or in aqueous or alcoholic extract of the foot muscle of the snail, when placed in aqueous or alcoholic extract of snails' hearts, began rhythmic pulsation 2-3 days after their isolation (20 experiments), thereby clearly indicating the existence of a heart-stimulating substance in invertebrates. In 22 experiments a preparation of epinephrine-free and histamine-free cardiac hormone from beef-hearts proved effective on the heart of *H. pomatia,* inducing, accelerating, and strengthening the pulse-beat in dilutions up to $1:10^6$, and thereby furnishing a new illustration of the effect of vertebrate hormonal substance on invertebrates. In 33 experiments on the hearts of *Aplysia limacina, A. depilans* and *A. punctata* the results were even more striking, since *Aplysia* hearts could be made to resume pulsation even after 3 days and by dilutions up to $1:10^{17}$.

778. **HAHN, JAR. Über den Einfluss der Schilddrüsenfütterung auf die Metamorphose der Vanessa io und der Tenebrio molitor.** *Zeitschr. Wissensch. Biol. Abt. D. Roux' Arch. Entwicklungsmech. Organ.* 115(1/2): 336-359. 6 fig. 1929.—Experiments with caterpillars of *Vanessa io* resulted in a retardation of development and a weight increase. Experiments with Tenebrio molitor were negative. These experiments support the opinion of the authors, who deny a positive and specific influence of the thyroid gland on invertebrates.—*H. Pribram.*

779. **HANNAN, JOHN H. Ovarian transplantation.** *Jour. Obstetr. & Gynecol. Brit. Empire* 36(3): 569-575. 1929.—A series of transplants of ovaries from cats and rabbits were made into ovariectomized rabbits. The site chosen for transplantation was between the deep and superficial fascia of the back below the last rib. The whole ovary was transplanted without section. Transplants examined histologically at intervals up to 12 weeks showed progressive retrogression and disappearance of germinal epithelium and follicles and final removal of ovarian tissue. The conclusion drawn is that iso- and hetero-transplantations are not justified as remedial measures in cases of hypo-ovarian endocrine disturbances.—*E. Allen.*

780. **HARINGTON, CHARLES R., and W. T. SALTER. The isolation of l-Thyroxine from the thyroid gland by the action of proteolytic enzymes.** *Biochem. Jour.* 24(2): 456-471. 1930.—A method, which employs pepsin, was described for isolating thyroxine. The thyroxine was levorotatory, and had a specific rotation of $[\alpha]_{5461} - 3.8$ as the sodium salt in 60% alcoholic solution. The digestion product (1.3 mgm. per diem for 6 days of a preparation containing 50% of I) produced an increase in O consumption of 85% in the rat when given orally, while pure *l*-thyroxine had no effect. There was less physiological difference when they were injected subcutaneously. Trypsin did not liberate I from diiodotyrosine within 5 mos. Several methods were described which showed how the early stages of the digestion of thyroid gland by pepsin and trypsin was carried out. The purified digestion product consisted of a mixture of free thyroxine with thyroxine peptides.—*E. B. Carmichael.*

781. **HAUROWITZ, FELIX, und MAX REISS. Versuche zur Biologie und Chemie des Hypophysenvorderlappen-Sexualhormons.** *Naturwiss. Zeitschr. Lotos* 77 (5/12): 255-256. 1929.—An abstract. Methods of purification are briefly indicated. The hormone is split by peptone-splitting enzymes, hence it is probably near the peptones chemically; but it is not salted out by $(NH_4)_2SO_4$ and it passes a semi-permeable membrane. It is probably a peptone with an active prosthetic group. It is not distinguishable from, and may be identical with, the hormone found in the urine of pregnancy.

782. **HEIDRICH, L., E. FELS, und E. MATHIAS. Testikuläres Chorionepitheliom mit Gynäkomastie und mit einigen Schwangerschaftserscheinungen. Gleichzeitig ein Beitrag zur Pathologie der hormonalaktiven Gewächse.** *Bruns' Beitr. Klin. Chir.* 150(3): 349-384. 5 pl. (4 col.), 11 fig. 1930.—Trauma to the left testicle; produced local swelling, painful enlargement of the breasts and profuse secretion of colostrum. The testicular growth on removal presented the structure of a chorionepithelioma of teratoid origin. Metastases had been formed in the abdomen, neck and lungs; the mammary enlargement and secretion continued. At the patient's death, about 10 mos. after the original trauma, the structure of the hypophysis was found to be that of the 7th or 8th month of pregnancy. The metastases were of pure chorionepitheliomatous type. The patient's urine, tested at various intervals before his death, showed the presence of ♀ sexual hormone and of increasing quantities of the hormone of the anterior lobe of the hypophysis (Aschheim-Zondek test for pregnancy).

783. **HERREN, R. YORKE, and H. O. HATERIUS. The relation of ovarian hormones to electro-myographically determined Achilles reflex time.** *Amer. Jour. Physiol.* 96(1): 214-220. 1931.—Determination on 16 ♀ rats through 30 oestrous cycles showed a long Achilles reflex time during the oestrous period and a short Achilles reflex time during the dioestrous period. Determinations on castrates indicated a lengthened Achilles reflex time following injection of extract of follicular fluid and a shortened Achilles reflex time consequent to injections of extract of corpus luteum, whereas controls displayed no significant change. The pregnant animal was characterized by a gradual decrease in Achilles reflex time until the 10th or 11th day of term, at which time a gradual increase in reflex time appeared, culminating in the extremely long reflex time of parturition. Pseudo-pregnant animals showed a gradual decrease in Achilles reflex time corresponding in length to the functional life of the corpora lutea of pregnancy. It is concluded that the sex hormones play a vital part in the interaction of the various neural levels, either through direct influence on nervous tissues of higher levels, or indirectly through other connections with the higher levels.—*Authors' summary.*

784. **HILL, MARGARET, and A. S. PARKES. The relation between the anterior pituitary body and the gonads. Part I. The factors concerned in the formation of the corpus luteum.** *Proc. Roy. Soc.* [*London*] *B* 107 (748): 30-38. 1 pl. 1930.—Extracts containing the gonad-stimulating principle of the anterior pituitary body were prepared from urine of pregnancy by a method similar to those employed by Zondek and Aschheim and by Evans and Simpson. Ovulation was produced freely in non-copulated oestrous rabbits by one intravenous injection of these preparations. It has not so far been possible to correlate the number of follicles ovulating, or even the occurrence of ovulation, with the dosage given. Following ovulation induced by this means corpora lutea develop and function without extraneous assistance; the result being a period of pseudo-pregnant development in the uterus and mammary glands. Pseudo-pregnancy thus induced is of the normal length, and has the usual characteristic features. The fact that corpora lutea develop after ovulation induced without copulation shows that the stimulus to luteinisation of the ruptured follicle is initiated by the actual act of ovulation and not as a delayed effect of copulation.—*Authors' summary.*

785. **HILL, MARGARET, and A. S. PARKES. On the relation between the anterior pituitary body and the gonads. Part II. The induction of ovulation in the anoestrous ferret.** *Proc. Roy. Soc.* [*London*] *B* 107(748): 39-49. 3 pl. 1930.—Ovulation may be induced in the anoestrous ferret by the administration of certain preparations containing the gonad-stimulating substance or substances of the anterior pituitary body. Other preparations, however, resulted in the formation of large cystic follicles or in the coincident growth and partial luteinisation of follicles. In all cases where ovulation occurred,

as well as in many others, the anoestrous accessory organs (uterus, vagina and vulva) underwent the changes typical of oestrus as a result of the ovarian stimulation. Following ovulation, corpora lutea develop and function with or without further administration of extracts. In correlation with this ovarian development, pseudo-pregnant changes take place in the uterus. Owing to failure to induce spermatogenesis in the male, pregnancy was not obtained during anoestrus, though copulation occurred between treated males and treated females. There can be little doubt, however, that the ova from the induced ovulations were fertilisable, and that implantation could have taken place.—*Authors' summary.*

786. HIMWICH, H. E., and F. W. HAYNES. Effects of posterior pituitary extracts on basal metabolism. *Amer. Jour. Physiol.* 96(3): 640-646. 1931.—In 64 experiments on 20 rats the changes in O consumption, CO_2 production and R.Q. after the subcutaneous injection of pituitrin, pitressin, and pitocin, were determined by Haldane's method. The decrease of the metabolic rate by pituitrin is due to pitressin and occurs despite the effect of pitocin, since pitressin markedly diminishes the metabolic rate, while pitocin increases it slightly, but definitely. Such opposing actions may explain some of the inconsistencies in the literature since the different preparations used by various observers may have contained varying amounts of the oxytocic and pressor principles. Moreover, some of the previous workers injected pituitrin peripherally in doses too small to produce definite changes, since in the present experiments effects on metabolic rate were observed only with large doses.—*Authors' summary and conclusions.*

787. HOGBEN, LANCELOT, and CECIL GORDON. Studies on the pituitary. VII. The separate identity of the pressor and melanophore principles. *Jour. Exp. Biol.* 7: 286-292. 1930.—When pituitary extracts are subjected to prolonged action of high concentrations of NaOH, the destruction of the pressor activity is accompanied by an appreciable increase in melanophore activity. This increase is ascribed to the fact that constriction of the vessels by the pressor component normally tends to mask the activity of the melanophore stimulant. It is suggested that the melanophore, pressor and oxytocic activities of pituitary extracts are referable to distinct entities.—*J. M. Robson.*

788. HORIE, KENJI. Experimentelle Untersuchungen über die Funktion der Nebenniere. I. Mitt. Die Nebennierenrinde und der Cholesterinstoffwechsel. [Japanese] *Mańshu Igakkwai Zasshi* 7(6): 1927.—The adrenal cortex plays an important rôle in the cholesterol metabolism of the rabbit. The excess cholesterol is infiltrated and stored in the adrenal cortex, to be utilized when needed.—*O. Mori (courtesy Japanese Jour. Zool.) (transl. by R. A. Muttkowski).*

789. HOUSSAY, B. A., y L. GIUSTI. Funcion sexual, hipófisis e hipotalamo en el sapo. [Sexual functions, pituitary and diencephalic in toads.] *Rev. Soc. Argentina Biol.* 6(2): 146-163. 1930.—Implantation of glandular lobe produces increase in volume and activity of testicles and subsequently increased sexual flexion reflex (not observed in castrates). Testicular implantation does not produce effects. Injection of large doses of testicular extracts produces flexion reflex in castrates. Cauterization of infundibulum produces intense flexion reflex even in castrates and after hypophysectomy. This last operation also produces ovulation and expulsion of ova which is not observed after extirpation of the pituitary or only the glandular lobe. Hypophysectomy or extirpation of glandular lobe when complete do not produce ovulation (rectifying previous communications). Pituitaries of *Bufo arenarum, B. d'orbigny* and *L. ocellatus* are active for these species. Alkaline extracts of mammalian pituitary, exceptionally produce incomplete ovulation in toads.—*J. T. Lewis.*

790. HOUSSAY, B. A., y L. GIUSTI. Funciones de la hipófisis y de la región infundíbulo-tuberiana del sapo Bufo arenarum (Hens.). [Functions of pituitary and infundibulum in Bufo arenarum (Hensel).] *Rev. Soc. Argentina Biol.* 6(3): 206-215. 1930.—Insufficiency of pars intermedia produces paleness, hyperfunction, darkening of the skin. Insufficiency of pars glandularis produces a) testicular atrophy, b) asthenia, convulsions and death, c) hypersensitiveness to insulin, d) attenuation or total absence of pancreatic diabetes, e) sometimes hypoglycemia and diminished hepatic glycogen content, f) arrested development (in other batrachians). Implantation of pars glandularis prevents the appearance or corrects these symptoms and produces opposite ones, besides ovulation and expulsion of ova. Symptoms of infundibular lesion are a) a bronzed epidermic cuticle, b) polyuria, c) reflex sexual flexion of anterior limbs even after hypophysectomy or gonadectomy. Lesion of tuber stimulates the melanophore-dilating secretion of pars intermedia, and the secretion that provokes ovulation; it inhibits the "diabetogenic" secretion.—*J. T. Lewis.*

791. HOWES, N. H. A histological study of the ox pituitary gland after freezing and exposure. *Jour. Exp. Biol.* 7: 253-259. 1930.—A series of cytoplasmic changes, corresponding to alterations in the biological activity and chemical content previously investigated, are observed in ox pituitary glands which have been exposed, after the death of the animal, to different temperatures for varying times. It would appear that freezing causes no alteration in the distribution of biological activity.—*J. M. Robson.*

792. HUG, ENRIQUE L. J. A. Hipófisis y crecimiento. [Hypophysis and growth.] 147p. Tesis, Univ. Nacional Buenos Aires, 1928.—A complete and accurate survey of literature up to date. Personal experiments are reported in detail. The pituitary was removed in 5 series of puppies using litter mates as controls. Careful postmortem microscopical examination of the operated region revealed in some cases remains of glandular tissue, in others removal was complete. In these and in animals with only small portions of gland, growth was retarded, the lag became evident from 1 to 2½ mos. after the operation and was more or less marked. In severe cases the animals had an infantile appearance:—short head; fine hair, short and soft; bone calcification retarded or stopped; persistence of decidual teeth, late appearance of second dentition but without macro- or microscopic lesions. Body temperature was frequently low. Basal metabolism was diminished and atypical, sexual organs under-developed. Atresia and sclerosis occurred in ovaries. The thyroids were usually of normal size but the epithelium was atrophied and the follicles distended with colloid. Marked loss of weight and cachexia were observed. No special sensitiveness to infection or disease was observed. Repeated intraperitoneal injections of fresh pituitary (ox, dog, sheep) and grafting of the pituitary had no effect on these symptoms. In 3 series infundibular lesions were made. Growth was not affected but in one case testicular atrophy was observed. Polyuria is usual in these animals.—*J. T. Lewis.*

793. IHRKE, I. A., and F. D'AMOUR. The influence of testis hormone upon the oestrous cycle in the rat. *Amer. Jour. Physiol.* 96(2): 289-295. 1931.—Daily injections of testis hormone into spayed ♀ rats did not stimulate the cornified vaginal smear of oestrus or have any demonstrable effect. Injection of mixtures of testis hormone and oestrin into spayed ♀♀ was accompanied by the cornified cell smear as long as injections were continued. When injections were stopped the leukocyte (or dioestrous) smear appeared and was permanent. Testis hormone injected daily into normal ♀♀ suppressed the oestrous cycle for the period of the injection. When injections were no longer given the normal cycle expressed by the vaginal smear reappeared. While the cycles were suppressed by testis hormone the oestrous smear could be induced by injection of hypophysis secretion. From this, together with preceding work, the authors conclude: (1) Sex hormones, whether produced by intact gonads or introduced by injection, stimulate the homologous sex characters in the organism but do not influence heterologous characters; (2) sex hormones do not have a direct influence upon either the homologous or heterol-

ogous gonad; (3) the sex stimulating secretion of the hypophysis controls the 2 functions of the gonad—the gametogenetic and endocrine functions; without the presence of this secretion both gonad functions are in abeyance; (4) gonad hormones of either sex act to depress the hypophysis and result in a lessened amount of hypophysis sex stimulating secretion available to the organism.

794. **INGRAM, W. R. Studies of amphibian neoteny. III. The Golgi apparatus of thyroid cells of Rana clamitans in relation to the anterior pituitary.** *Anat. Rec.* 46(3): 233-247. 1 pl. 1930.—Previous work having shown that the function of the anterior pituitary is related to thyroid activity and metamorphosis in *R. clamitans*, a partially neotenous anuran form, observations were extended to the Golgi apparatus of thyroid cells following implantation with adult anterior-lobe tissue. With the onset of greatly increased activity under this influence, the Golgi apparatus becomes large, extensive, and closely related to secretory substances; whereas in normal inactive glands it is very small. The position of the Golgi material varies, but cases of complete reversal in position were very rare, and in such cases no evidence of reversed direction of secretion was found. Since the general gross and histological picture in these metamorphosing amphibians resembles that in exophthalmic goiter in higher forms, the observations are compared with Ludford and Cramer's findings for this disease in mammals, and their relationship to various theories of the mechanism of thyroid secretion is discussed. Anterior-pituitary treatment as described has no effect on the gonads of the animals used in these experiments, hence it is suggested that it is the growth principle of the anterior lobe, apart from the sex-maturity principle, that is the controlling factor for thyroid activity and amphibian metamorphosis.—*Author (courtesy Wistar Bibl. Serv.).*

795. **JACQMIN, LOUIS. L'influence des hormones testiculaires sur la prédisposition au cancer.** *Rev. Belge Sci. Méd.* 1(9): 777-810. 1930.—Believing that the grafted tumor, foreign to the host organism, can scarcely explain why normal, native tissues at a given moment turn lawless and abnormal, Jacqmin has studied the cancer provoked by tar as offering the best parallel to spontaneous human cancer. I. White ♂ mice "castrated before puberty" and non-castrated ♀ controls (exact number not stated) were painted with tar for 2½ mos. Of the castrated mice 13 and of the non-castrated 14 survived the appearance of the 1st papilloma; 11 of the castrated and 13 of the controls survived the appearance of the 1st cancer. In the castrated mice there were 80% of cancers and 44% metastases, against 57% cancers and 14% metastases in the controls. The average survival of the castrates after appearance of cancer was 63 days, against 95 days in the controls. II. In a similar series of mice castrated after puberty, 17 castrates and 15 controls survived the appearance of the 1st papilloma; 14 castrates and 9 controls survived the appearance of the 1st cancer. The cancers appeared, on the average, on the 180th day in the castrates and on the 159th in the controls. The controls lived only 25 days after the appearance of cancer, while the castrates lived 75 days. There were, however, 50% of metastases among the castrates and none among the controls. III. Mice were castrated during the first 4 mos. of tar treatment. All the mice that lived 7 mos. after the beginning of the tar treatment (11 castrates and 12 controls) produced cancers; there were 73% of visceral metastases in the castrates and 33% in the controls. The castrated mice lived, on the average, 68 days after the appearance of cancer; the controls lived 52 days. IV. The vasa deferentia were ligated in another series of mice, and tar treatment begun 6 wks. later. Of the vasectomized mice 39 survived the appearance of the 1st papilloma and 36 the appearance of the 1st cancer; of the controls, 29 and 27 respectively. The vasectomized mice presented more tumors than the controls (78% against 53% at the end of the experiment) and earlier (153 days from the 1st tar treatment in the vasectomized against 168 days in the controls), but no more metastases. The survival after appearance of the 1st cancer was practically the same in vasectomized mice (53 days) and controls (52 days). V. Estas had previously shown that injection of ionium nitrate (which also sterilizes) favors the formation and growth of tar cancer. To determine whether castration and the consequent elimination of the testicular hormone has any effect greater than the mere suppression of spermatogenesis, Jacqmin gave 7 mice each an injection of ionium nitrate; then, some weeks later, castrated them and 4-6 wks. afterward began tar treatment. On the 150th day all presented cancers—a rapidity of result unparalleled in the experience of both Jacqmin and Estas. There were 72% of metastases. As no controls were available, the only basis for comparing with ionium injection not followed by castration is Estas' series, but Jacqmin believes himself justified in concluding that the effect of castration is added to that of ionium.

796. **JEFFRIES, M. E. Hormone production by experimental cryptorchid rat testes as indicated by the seminal vesicle and prostate-cytology tests.** *Anat. Rec.* 48 (1): 131-139. 1 pl. 1931.—A study of the reactions of the rat testis to experimental cryptorchidism, both from the standpoint of spermatogenetic activity and hormone production. Degeneration changes make their appearance in the germinal epithelium 3-5 days after elevation of the testis into the abdomen. It is rapidly progressive, but somewhat variable, and within 2-3 weeks practically all cells of the germinal line may have disappeared, or some tubules may continue to show dividing spermatogonia and perhaps spermatocytes, but spermatozoa are never found. The extensive destruction of germinal epithelium does not modify in any detectable manner the production of the internal secretion or hormone. Indicators of testis hormone, such as the cytology of the prostate gland and seminal vesicle, reported by Moore and coworkers, show these glands to be entirely normal 2 mos. after abdominal elevation of one testis and removal of the opposite one. Since the indicators serve to register hormone absence for periods as short as 3-5 days, it is concluded that hormone secretion by the severely injured testis suffers no interference. It is therefore evident that the function of spermatogenesis is unrelated to hormone secretion in the testis of the rat.—*Author (courtesy Wistar Bibl. Serv.).*

797. **JENSEN, H., und A. M. DeLAWDER. Über die Aktivierung von Insulin. Untersuchungen an kristallisiertem Insulin.** *Biochem. Zeitschr.* 225(1/3): 141-150. 1930.—It was found that neither crystalline insulin nor the commercial preparation "Iletin" could be activated by the addition of serum, enterokinase or yeast press juice. This finding is in contradiction to that of other investigators, who have used rather impure insulin preparations, which may explain the different results obtained. The possibility of slower absorption of insulin with the addition of the above named substances has been discussed. One is not justified, however, in saying that insulin has been activated. The question whether it is possible to activate insulin is still open.—*H. Jensen.*

798. **JUHN, MARY, and L. V. DOMM. The relation of gonadal condition to erythrocyte number in fowls.** *Amer. Jour. Physiol.* 94(3): 656-661. 1 fig. 1930.—The erythrocyte number was determined on 80 brown Leghorns, 40 ♂ and 40 ♀, at intervals from the day after hatching to 16 mos. of age. A definite sex dimorphism in the number of red cells was noted confirming other observations cited. The juvenile and the gonadectomised bird of either sex and the mature ♀ all show a similar erythrocyte number. The number of red cells is significantly higher in the adult ♂, the increase becomes apparent at the time of sexual maturity. Red counts (30) carried out in poulards show that the modifications in the ♂ direction noted after removal of the left ovary can now be extended to include the erythrocyte number which equals that of the adult ♂.—*Authors' summary.*

799. **KARPLUS, I. P., und O. PECZENIK. Über die Beeinflussung der Hypophysentätigkeit durch die Er-**

regung des Hypothalamus. *Pflüger's Arch. Ges. Physiol.* 225(5/6): 654-668. 4 fig. 1930.—Cisterna cerebro-spinal fluid following stimulation of the hypothalamus shows increased oxytocic and melanophore expanding activity. This is regarded as evidence of augmented pituitary secretion. Stimulation of the cervical sympathetic or of the sciatic, the effects of which resemble those produced by stimulation of the hypothalamus, do not affect pituitary secretion. In like manner section of the cervical sympathetics does not abolish the effect of hypothalamus stimulation upon pituitary secretion. It is concluded that the hypothalamus is the seat of the mechanism controlling the rate of liberation of the pituitary hormone into the cerebrospinal fluid.—*Authors' summary (transl. by M. I. Smith).*

800. KOLDA, JAROSLAV. Ústavní studie o rušení adrenalinu. 6.0 významu některých dalších kyselin při chemickém a světelném okysličování adrenalinu. [On destruction of adrenalin. 6. The effects of some acids on the chemical or photo-oxidation of adrenalin.] *Biol. Spisy Vysoké Školy Zvěrolékařské Brno (Publ. Biol. École Vétérinaires Brno)* 7: (135)-(142). 1928.—Adrenalin was dissolved in phosphoric, hypophosphoric, phosphorous, lactic, citric, trichloracetic or sulphuric acid; in all cases the solution had a pH of 4.0. It was also dissolved in a sodium benzoate solution of pH 5.8 or 6.2. Adrenalin was oxidized by H_2O_2 or by ultraviolet or visible rays or a mixture of both rays. H_2O_2 oxidizes adrenalin dissolved in H_2SO_4 at the slowest, adrenalin dissolved in phosphorous acid at the highest rate. Photo-oxidation is slowest in H_2SO_4, fastest in the benzoate solution. Rate of oxidation of ultraviolet and visible rays is about the same, both rays together have a stronger effect.—*Author's German summary (transl. by G. T. Cori).*

801. KORENCHEVSKY, V. The influence of cryptorchidism and of castration on body weight, fat deposition, the sexual and endocrine organs of male rats. *Jour. Path. & Bact.* 33(3): 607-636. 1930.—Experiments were performed on 185 rats. In both-sided cryptorchid rats the deposition of body fat is increased and a considerable atrophy of the penis, prostate, seminal vesicles and thyroids occurs. If only one testis is made cryptorchid and the other left normal, the changes are less constant and much less pronounced. Castration of rats is followed by a decrease of body weight, an increase in fat deposition, a striking atrophy of the penis, prostate and seminal vesicles and a considerable atrophy of the thyroids. The adrenals and the hypophysis are hypertrophied. The analysis of the data obtained shows the presence of sexual hormones, both in seminiferous and in Leydig's cells. A comparison of the weights of the fat and of the organs investigated, in rats belonging to the same litter, does not usually give large variations in the figures obtained, whilst in rats belonging to different litters the variations may be very great.—*V. Korenchevsky.*

802. KORENCHEVSKY, V. Experimental cryptorchidism of pigs. *Jour. Path. & Bact.* 33(3): 683-687. 1 col. pl. 1930.—Two domestic pigs were made cryptorchid and compared with two castrated litter mates. The final weight of the cryptorchid pigs was greater than that of the castrated pigs by 13.2%. The amount of retroperitoneal fat, but not that of subcutaneous fat, was slightly increased in cryptorchid pigs and they were more hairy than the castrates. Histologically in the testes the seminiferous tissue seemed to have disappeared, the Sertoli's cells were normal, whereas the hyperplasia of Leydig's cells was greater than in any other species of animal made cryptorchid.—*V. Korenchevsky.*

803. KOSAKAÉ, JIRO. Beiträge zur Kenntnis der Wehenauslösung. IV. Beiträge zur Gefässwirkung des Placentaextraktes und über die Kombinationswirkung desselben mit einigen anderen Wehenmitteln auf die Gefässe. V. Untersuchungen über die Bewegung des Uterus in situ des Kaninchens mit zerstörter Hypophyse. Schlussbetrachtungen über alle Untersuchungen in Bezug auf die Wehenauslöung. VI. Untersuchungen über den Einfluss der Placenta auf die uteruserregende Kraft des Ventrikelliquors. VII. Untersuchungen über den Einfluss des dem Körper zugeführten Mittels auf die uteruserregende Kraft des Ventrikelliquor des Kaninchens. VIII. Untersuchungen über die Bewegung des Kaninchenuterus in situ nach der Einführung einiger Mittel in den IV. Ventrikel. IX. Untersuchungen über den Einfluss der Placenta auf die vasopressorische und uteruserregende Kraft des Ventrikelliquor und des Serums. *Japanese Jour. Obstetr. and Gynecol.* 13(3): 238-243; 244-256; 257-266; 267-273; 274-290; 291-297. 1930.—[Nos. 1-3 of the series were not published under the series title. They were: I. Ueber die Wirkung von Kombination der Uterusmittel. *Zeitschr. Geburtsh. u. Gynäkol.* 85: II. Ueber die Wirkung von Placentaextrakten auf die Speichelsekretion. *Biochem. Zeitschr.* 130: III. Pharmakologische Untersuchungen über die Wirkung des Placentaextraktes. *Japanese Jour. Obstetr. and Gynecol.* 11: IV. Placenta extract had been found to produce vasodilatation in most vessels of warm- and cold-blooded animals; only in the vessels of the rabbit's ear and kidneys was it a vasoconstrictor. These and other effects (stimulation of the uterus, narrowing of the pupils, increase of lacrimal and salivary secretion, cardiac inhibition and lowering of blood-pressure) indicated that the action of placenta extract is predominantly a stimulation of the parasympathetic. The effect of placenta extract on a rabbit's ear preparation in which the parasympathetic action had been previously excluded by atropin (likewise a vasodilator) was found to be distinctly lowered. Hence placenta extract appears to act on the endings of the parasympathetic nerves. The extract sometimes showed an effect on muscle by hindering the toxic action of $BaCl_2$. No enhanced effect on the vessels of the ear preparation or the toad's leg was to be observed from combination of pituitrin or secacornin with placenta extract. V. The hypophysis was partially removed from 5 sexually mature ♀ rabbits, and 10-25 days later they received intravenous injections of placenta extract, which was likewise given to 4 controls. In 2 out of the 5 operated animals the uterine contractions from placenta extract were greatly weakened. In 8 other ♀ rabbits the hypophysis was almost or quite completely removed, and placenta extract given 2-23 days later; in 4 of these the uterine contractions were practically abolished, and in none of the remainder were the contractions of normal strength or frequency. Kosakaé maintains, consequently, that the corpus luteum and the ovarian hormone have nothing to do with initiating birth; this is caused, he believes, by the action of matured placenta substance at the end of pregnancy on the posterior lobe of the hypophysis, which thereupon initiates uterine contractions. VI. Proceeding on the basis of Herring's hypothesis that the secretion of the posterior lobe of the hypophysis is excreted into the 3rd ventricle, Kosakaé studied the action of the ventricular fluid from non-pregnant, pregnant and puerperal rabbits, untreated and previously treated with placenta extract, preparation of hypophysis posterior lobe, and both combined. He found the uterus-stimulating power different according to the sexual period, strongest in pregnancy, next strongest in puerperium; increased by subcutaneous injection of either placenta extract or hypophysis posterior lobe preparation (still more by both), the increase being most effective in pregnancy. In a hypophysectomized rabbit, despite injection of both placenta extract and pituitrin, the ventricular fluid had no uterus-stimulating power. Kosakaé concludes that the increase of the uterus-stimulating power of the ventricular fluid after injection of placenta extract is due to stimulation of the posterior lobe of the hypophysis; and that the intensification of the action of placenta extract by simultaneous administration of posterior lobe of hypophysis is due mainly to increased activity of that organ, and in some slight degree to the direct infusion of the injected substance into the ventricular fluid. VII. The effect of the ventricular fluid of the rabbit on the surviving excised uterus of the guinea-pig was found to be markedly decreased by previous subcutaneous or intravenous injection of the rabbit with epinephrine or

secacornin, but enhanced by previous injection of pilocarpin. All of these effects are attributed to the action on the posterior lobe of the hypophysis of epinephrine and secacornin; these substances, given simultaneously with placenta extract, likewise inhibit its action. VIII. In this series of experiments the substances investigated were injected into the 4th ventricle of rabbits and the effect on the uterus in situ noted. Preparation of hypophysis posterior lobe (5 rabbits), placenta extract (2 rabbits), the 2 substances combined (3 rabbits), epinephrine (3 rabbits) and pilocarpin (1 rabbit), injected into the ventricle, all had a weaker uterine effect than when intravenously introduced, and their toxicity seemed greater. Pilocarpin displayed no immediate effect, but later regularized the spontaneous contractions. Preparation of posterior lobe of the hypophysis produced somewhat different effects according to the amount of substance and the condition of the uterus. A small amount soon reduced the untreated uterus to immobility, while it caused increase of tonus in the sensitized uterus. A large amount produced transient contractions, which might be preceded by inhibition. This immediate inhibiting effect is attributable to the action on a center of 1 of the substances in the preparation; the later effect tends to establish rhythmic action. Placenta extract, alone and combined with preparation of hypophysis posterior lobe, given intraventricularly, has the same effect as the latter alone. These data indicate that the effect of the so-called uterus-contracting substances, given intracisternally, manifests itself only when the substance affects the uterus itself peripherally. A central action follows these intraventricular injections as a secondary effect of the increased function of the posterior lobe of the hypophysis, raising the activity of the uterus several hrs. later. IX. A mixture of placenta extract and pituitrin was subcutaneously given to 15 normal rabbits (3 cc. in 3 hourly injections to each rabbit); 1 hr. after the last injection ventricular fluid was taken from 13 of them, and 3 hrs. later sera from 12. These fluids and sera were tested by intravenous injection in 6 rabbits. Of the 13 ventricular fluids 10 produced more or less marked increase in uterine movements; so did 10 of the 12 sera; but in no case was there any change in blood-pressure.

804. **KRAUS, E. J. Zur Frage der Funktion fötaler endokriner Organe.** *Beitr. Pathol. Anat. u. Allg. Pathol.* 82(2): 291-306. 4 fig. 1929.—Following a critical analysis of researches by other workers and after a careful study of a case of total congenital thyroid aplasia, the author reaches the following conclusions: The opinion that the fetal endocrines are inactive and that the fetus is dependent solely upon the hormones of the mother is erroneous. The remarkable changes in the pituitary, thymus and adrenals, observed in a case of congenital thyroid aplasia, indicate an intimate relationship between the thyroid and the above-mentioned glands during embryonic life. This relationship must depend upon the interaction of their hormones, necessitating, therefore, endocrine activity. The origin of the striking alterations shown in the endocrine system in such cases can only be explained by accepting function on the part of these glands in the embryo. Certain changes observed in cases of anencephaly can only be explained on the same basis. Evidence of the specific function of a gland is seen by the presence of a specific active substance within the gland (epinephrine in the adrenal, an oestrus producing hormone and the hormone producing the melanophore reaction in the pituitary, insulin in the pancreas, I in the thyroid, etc.). The demonstration of the presence of these hormones within the gland does not necessarily prove that the hormones reach the circulation. A consideration of the findings in the above-mentioned case of thyroid aplasia, also in cases of genital-suprarenal syndromes in the new-born, and the manifestations of isolated cases of congenital acromegaly and Basedow's disease indicate that these hormones reach the circulation during embryonic life. Fetal endocrines are probably supported at first by the maternal endocrines although proof of this is difficult. The changes in this case of congenital thyroid aplasia do not indicate that the maternal endocrine system supplemented the deficient fetal thyroid to an adequate degree. Rather, there is evidence that deficiencies of the maternal endocrines are supplemented by those of the fetus. Hyperplastic changes in the thyroids of the offspring of thyroidectomized dogs, hyperplastic changes in the Islands of Langerhans in the children of diabetic mothers, and the researches of Carlson and Drennan appear to support this point-of-view. "Thyreoprive Zellen" is the name proposed for the chromophobe cells appearing in the anterior lobe of the pituitary in cases of thyroid aplasia. These cells, according to Wegelin, are comparable to the transitional cells of E. J. Kraus.—*H. C. Mack.*

805. **KUNDE, M. M., R. M. OSLUND, and R. KERN. The temporary control of post-operative tetany in thyro-parathyroidectomized dogs by the administration of thyroid hormone.** *Amer. Jour. Physiol.* 96(1): 45-53. 1931.—In approximately 55% of a series of 31 dogs, tetany following thyro-parathyroidectomy was temporarily controlled by experimental hyperthyroidism. The remaining 45% died as in uncontrolled tetany. Experimental hyperthyroidism maintained the serum Ca above the tetany level for 1-3 wks. in 55% of a series of 31 thyro-parathyroidectomized dogs. In all thyro-parathyroidectomized dogs of this series, a further decrease in the serum Ca followed the discontinuance of thyroid ingestion. In the unoperated animals, moderately severe hyperthyroidism, experimentally induced, causes an elevation in the level of the acid soluble P of the blood serum which may reach 100% above normal, with no change in the serum Ca. After thyro-parathyroidectomy, the increased concentration of the blood P persists, or shows a tendency to a still higher elevation with increased severity of the hyperthyroidism, regardless of the decrease in the serum Ca.—*Authors' summary.*

806. **KUNDE, M. M., F. E. D'AMOUR, R. G. GUSTAVSON, and A. J. CARLSON. The effect of estrin administration on the reproductive and blood vascular systems: the thyroid, thymus, hypophysis, adrenals, kidneys, liver and spleen.** *Amer. Jour. Physiol.* 96(3): 677-682. 1931.—In 4 puppies (3 ♀♀ and 1 ♂), 7-9 wks. old at the beginning of the experiment, subcutaneous injections of oestrin over a period of 6-17 wks. caused a diminution of the size of the ovaries, an arrest in the development of the follicles and a relative increase in the amount of ovarian stroma, as compared with 2 controls. Marked hyperplasia of the uterine glands (especially the basal glands) followed oestrin injections but no hemorrhagic discharge from the vagina was observed. The hypophysis of the dog receiving ♀ sex hormone for 17 wks. was smaller than the hypophysis of the control, and measurements indicate a relatively greater decrease in the anterior than in the posterior lobe. Neither gross nor histopathology was observed in the arteries, heart, liver, spleen, thymus or adrenals after 17 wks. of daily doses of ♀ sex hormone.

807. **LA BARRE, JEAN. The rôle of the central nervous system in the control of pancreatic secretion. I. The secretion of insulin during hyperglycemia. II. The external secretion of the pancreas during hyperglycemia.** *Amer. Jour. Physiol.* 94(1): 13-16. 1 fig. 17-21. 1930.—I. The complete technique involved the use of 3 dogs. The head of dog B was kept alive by a double cross-circulation between B's head and the trunk of dog A. The head of B was isolated completely from its trunk except for the 2 pneumogastric nerves. There was then made an anastomosis between the pancreatic vein of dog B and the jugular vein of dog C. Dog C was the test-object for hypernormal insulin-secretion by dog B. With such preparations, the author performed 2 series of experiments. In the 1st series, before establishing a double cross-circulation between dogs A and B, he removed the cerebral hemispheres of the isolated head of B. In a 2nd series of experiments, before establishing the transfusion of the isolated head, he removed not only the cerebral hemispheres but also the thalamic region. The hyperinsulinemia resulting from the transfusion of hypergly-

cemic blood through the isolated head of the dog was not affected by the removal of the cerebral hemispheres but was abolished by the separation of the thalamic region from the remainder of the central nervous system. II. In 2nd series, 3 experiments, a 2nd injection of dextrose given when the effect of the 1st injection had almost disappeared produced a repeated sudden increase of the external pancreatic secretion. The 3rd series, 5 experiments, was a study of the influence of hyperglycemia on the external pancreatic secretion in animals with cerebral hemispheres and thalamus excluded by a retrothalamic section. The conclusion is that the extirpation of the cerebral hemispheres does not modify the increase of the pancreatic-juice flow consequent to hyperglycemia. Extirpation of the thalamus abolishes the response.

808. **LAQUEUR, E., E. DINGEMANSE, and S. KROBER. Crystalline "Menformon."** *Nature [London]* 125 (3142): 90. 1930.—A progress report. A product in the form of macrocrystals (colorless platelets), similar to those reported by Doisy, were obtained.

809. **LEBEDINSKY, N. G. Bekämpfung der Alterserscheinungen durch teilweises Zerreissen und Zerdrücken des Hodengewebes. Versuche an Hunden.** *Biol. Zentralbl.* 50(7): 392-422. 12 fig. 1930.—Four dogs of 10½ to 11½ years of age were pricked through the scrotum with long bent needles and a fraction of the testis torn or crushed. Senile characteristics such as indifference, non-interest in food, weakened sense perceptions, quick fatigue, stiffness of the body and quivering of the hind legs, were markedly relieved. This improved condition, including a partial return of eroticism, has endured for 9 mos. Histological study after 6 mos. on one of the experimental dogs showed a general atrophy in the traumatized area, but an increase of Leydig's cells in the adjacent area. Products of torn tubules cannot reach the outside of the body; hence this method of "rejuvenation" is intrinsically comparable to vasectomy, ligaturing, and other methods of damming the testicular products. But since only a small fraction of the testis is destroyed in the present method, the products can still reach the outside of the body, as the epididymis and vas deferens remain whole.—*From abst. by N. G. Lebedinsky (transl. by R. A. Muttkowski).*

Ital.* 41(6): 151-155. 1930.—A census of the islets of Langerhans in normal and castrated *Mus musculus*, studied by means of serial sections, shows no numerical change in the islets after total castration of either sex. No structural modifications are found in the islets of the castrates; nor was any correlated growth observed among the exocrine acini. The thyroids in castrates present signs of hypofunction, but the islets are maintained unaltered. —*G. Lentati (transl. by R. A. Muttkowski).*

811. **LENART, GEORG, und CHARLOTTE REIS. Parathormon-eosinophile Untersuchungen bei gesunden Kindern.** *Arch. Kinderheilk.* 92(3/4): 161-169. 1931.—Since variations in the Ca content of the blood are accompanied (not causally) by proportional, though inverse, changes in the eosinophil count, the latter was tested in healthy children and found practical as an index of parathormone sensitivity. In 11 children after subcutaneous injection of 1 unit of parathormone per kgm. body wt., the absolute number and the percentage of eosinophils dropped at the 5th hr. and returned to normal at the 24th in all but 2 infants, in whom it was nomal at 48th hr.

812. **LEWIT, S. G., N. S. BERLAND, und I. A. RYWKIN. Die biologische Kontrolle des Antithyreoidins.** *Zeitschr. Ges. Exp. Med.* 71(3/4): 506-524. 1930.—The authors criticize the reports of previous investigators. They have covered the same ground as Asimoff, using thyreocrin and antithyreocrin, preparations corresponding to thyroidin and antithyroidin, in their effect on the metamorphosis of 120 axolotls. Feeding with a mixture of thyreocrin and antithyreocrin, or with a mixture of thyreocrin and dried ox blood, produced an almost complete arrest of metamorphosis. Neither antithyroidin alone, nor normal blood alone, restrained metamorphosis. The authors regard it as completely proved that antithyreocrin has no specific anti-thyroid action.

813. **LINFORD, H. L'électromyogramme, l'électroneurogramme et l'électromyélogramme de la grenouille surrénalectomisée.** *Jour. Physiol. et Path. Gén.* 28(2): 361-369. 12 fig. 1930.—The post-operative effects, such as loss of spinal reflexes and death, after adrenalectomy in the frog are not characteristic of any particular condition. No difference could be found between the nerve-reactions of an adrenalectomised frog and a control animal in the same state of health.—*W. R. Fearon.*

814. **LORETO, C. Ricerche sulle variazioni del chimismo gastrico dopo paratiroidectomia sperimentale. (Nota preventiva.) [Variations in gastric chemistry after experimental parathyroidectomy.]** *Ann. Ital. Chir.* 9(11): 1169-1176. 1930.—In parathyroidectomized dogs [number not stated], surviving the operation 30-48 hrs., Loreto found slight diminution of the total acidity of the gastric juice taken during survival period, and, in the gastric mucosa immediately after death, hyperemia of an extensive zone of the base of the gastric mucosa and often little zones of submucous hemorrhage.—*Author's summary (transl.).*

815. **LOWE, ESTHER. Seasonal and sexual variation in the thyroid glands of cats.** *Quart. Jour. Microscop. Sci.* 73(4): 577-592. 2 pl. 1930.—A sex difference in the condition of the glands was apparent only during the period October–December when the glands of males contained far more colloid than those of females. Both sexes were producing a small amount of new secretion. During the rest of the year seasonal changes affected both sexes equally. Increased activity took place in January and February, followed in March by a more passive condition. From June–August they were again actively secreting. The glands of pregnant females were more actively secreting than those of non-pregnant females but varied in accordance with the seasonal variation recorded for normal males and females.—*E. Lowe.*

816. **LUKÁCS, J. Geht das Schilddrüsenhormon in die Milch über?** *Arch. Kinderheilk.* 91(1/2): 9-13. 1930.—Earlier experiments had shown that the growth of young white rats was proportionally retarded by experimental hyperthyroidism. Experiments here reported show the effect on suckling rats of thyroid feeding to the mother. Taking as 100% the gain in weight of 4 control litters (31 rats) suckled by normal mothers, 6 litters (51 rats) suckled by mothers fed on thyroid gained 46%-69%. This Lukács regards as evidence that the thyroid hormone produced in the maternal organism is excreted with the milk.

818. **MACLEOD, J. J. R. Some recent experiments with insulin.** *Leopoldina* 4:1-5. 1929.—A description of 2 depancreatized dogs, kept alive and in good condition for 4 years on a diet of meat, pancreas, and sugar, with daily injections of insulin. The carbohydrate balance and energy exchange were carefully followed. The author concludes that pancreatic enzymes are essential to the well-being of the animal, that the power to metabolize carbohydrate may be regained in certain cases, and that sugar may be derived from fatty acids in diabetes. —*T. C. Burnett.*

819. **MAHNERT, A. Die Wirkung von Sexual- und Hypophysenvorderlappenhormon auf die Abderhaldensche Fermentreaktion.** *Monatsschr. Geburtsh. u. Gynäkol.* 85(2/3): 94-97. 1930.—The occurrence of occasional negative Abderhalden reactions in undoubtedly pregnant women suggested that unknown influences, possibly hormones, may sometimes inhibit the working of the reaction. The 1st series consisted of the addition of sexual hormone, or hormone of the anterior lobe of the hypoph-

ysis, to the sera of 10 normal, non-pregnant women; such addition did not enable these sera to split placenta proteins. The next series consisted of experiments on 20 sera from pregnant women, who previously had given positive Abderhalden reactions. Addition of the hormones named clearly weakened the action of sera which had given strongly positive reactions, but had practically no effect on those which gave weakly positive reactions. Mahnert concludes that a physiologic increase of hormones in the blood and urine may account for occasional negative reactions in pregnant patients. The final series consisted of experiments to determine the cause of this inhibiting action of the hormones. Sera or urines from pregnant women were divided, ½ of each specimen having pulverized placenta mixed with it and then centrifuged off, the other ½ left untreated, and both parts injected into ♀ infant mice. The action of the 2 parts was practically the same, indicating that there was no adsorption or binding of the hormones by the placental protein. Hence the inhibition of ferment activity by hormones is to be regarded as an action on the ferment itself and not on the placental substrate.

820. **MARAÑON, G. L'influence sexuelle des glandes endocrines non-genitales. L'action virilisante de la substance cortico-surrenale et de l'hypophyse.** *Rev. Franç. Endocrin.* 8(1): 1-23. 1930.—Hormonal influences on sexual evolution are of two sorts, gonadal and extragonadal. Of the latter there are again 2 kinds, 1 of which seems active for sexuality in both sexes, the other is specific for one or the other sex. Adrenal and hypophysis produce substances of a virilizing type, which seem to be independent of their other hormonal effects.—*B. Cunningham.*

821. **MARFORI, PIO. Sui principi attivi della linfoganglina. [On the active principles of lymphoganglin.]** *Arch. Fisiol.* 28(3): 550-551. 1930.—Against Viale's assertion the author denies that cholin may be the active "hypotensive" principle of lymphoganglin.—*M. Comel.*

822. **MARRIAN, G. F. The chemistry of oestrin. III. An improved method of preparation and the isolation of active crystalline material.** *Biochem. Jour.* 24 (2): 435-445. 1 pl. 1930.—By acidification and ether-extraction of urine from pregnant women 8000 to 40,000 mouse units of oestrin were obtained per litre. These extracts were purified with a loss of 28-40% of the activity. The mouse unit of the purified preparations is about 0.0006 mgm. A crystalline material was obtained from the above preparations which had a potency of about 5 times that of the original.—*E. B. Carmichael.*

823. **MARRIAN, G. F., and A. S. PARKES. The assay of oestrin.** *Jour. Physiol.* 67(4/6): 389-401. 3 fig. 1929.—A discussion of the variable factors affecting the standardization of oestrin is followed by the description of a convenient technic. It consists of 4 injections at 12 hr. intervals.—*T. C. Burnett.*

824. **MASON, JAMES B., J. MARKOWITZ, and FRANK C. MANN. A plethysmographic study of the thyroid gland of the dog.** *Amer. Jour. Physiol.* 94(1): 125-134. 3 fig. 1930.—A method of plethysmography of the thyroid gland is described. The effects of various drugs on the volume of the thyroid gland were studied. The effects of epinephrine, nicotin, nitroglycerin, pilocarpin, acetyl cholin, atropin, pituitrin, rattlesnake venom, thyroid extract, and thyroxin are explicable on a circulatory basis. Strophanthin, KI, and caffein sodium benzoate have little, if any, effect. The effects on volume of the thyroid gland are recorded following stimulation of the vagus and sympathetic nerves in the neck and thorax. These experiments have demonstrated that the vasoconstrictor fibers pass to the thyroid gland by way of the sympathetic nerves. Following stimulation of the homolateral vagus nerve in the thorax, before its juncture with the sympathetic trunk, or following stimulation of the opposite vagosympathetic trunk, there is produced an increase in the volume of the thyroid gland. This was considered to be secondary to increased flow of blood consequent on the concomitant rise in blood pressure. The opportunity often presented itself for studying the reactions of hypertrophied glands to the stimuli mentioned. The results were identical with what occurred in non-goitrous animals. As might be expected, changes in volume were correspondingly greater in large goitrous glands. In several instances the authors' experiments were repeated on animals that had been rendered hyperthyroid by injecting thyroxine, or by feeding desiccated thyroid gland. The results were unaffected.—*Authors' summary.*

825. **MEYTHALER, F., und E. STAHNKE. Die Wirkung des Pankreashormons bei experimenteller Umgehung der physiologischen Leberpassage.** *Arch. Klin. Chir.* 162(Kongressbericht): 272-273. 1930.—The pancreatic hormone was conducted directly into the systemic circulation by anastomosis between the venae pancreaticoduodenales and the right vena renalis in 4 dogs. The fasting blood sugar fell from 85-110 mgm. % to 50-68 mgm. %. Administration of 100 gm. glucose by mouth, which before operation had produced alimentary hyperglycemia of as much as 200 mgm. %, after operation caused only a slight rise. Introduction of insulin directly into the systemic circulation in these experiments, the authors conclude, deprived the liver of the power to stabilize the blood sugar within the physiologic limits of 80-100 mgm. %. Epinephrine produced no hyperglycemia in these dogs.

826. **MINAMIKAWA, K. Experimental investigation of the effect of the nervous system on the function of the genital organs. V. Relation between the maturation of the genitals due to Zondek-Aschheim's hormone of the anterior pituitary lobe and sympathectomy.** *Japanese Jour. Obstetr. and Gynecol.* 13(5): 546-550. 1930.—Preliminary experiments on 16 rabbits confirmed the results of Aschheim and Zondek from injection of urine of pregnant women. Next, unilateral sympathectomy was performed on an unspecified number of young rabbits, and a series of injections of urine (taken during the 7th-8th mo. of human pregnancy) was made at various intervals after the operation; 96 hrs. after the beginning of injections the uterus and ovaries were removed for examination. Both, but particularly the ovaries, were markedly hypertrophied, generally far more so on the operated than on the unoperated side—invariably when the injection was begun in the 2nd wk. after sympathectomy; in this case the number of hemorrhagic follicles and corpora lutea was greater on the operated than on the unoperated side. No such difference was perceptible in the corpora lutea and follicles of the 2 sides when the injections were begun 1 mo. after sympathectomy, and the difference in hypertrophy of the 2 sides was progressively less in cases in which the injections were begun on the 30th-40th day after sympathectomy.

827. **MISSAL, MORRIS E., and MARGARET WOODWELL JOHNSTON. The failure of pituitary substances to influence the basal metabolism or the specific dynamic response to food in a normal subject.** *Jour. Lab. & Clin. Med.* 14(4): 314-321. 1929.—The oral administration of whole pituitary substance (Wilson) for 16 days and the intramuscular injection of antuitrin (Parke-Davis) for 7 days and pituitary solution obstetrical (Wilson) for 11 days were without effect on the basal metabolism or respiratory quotient of an apparently normal man on a constant diet. In experiments in which the increase in metabolism was determined following the ingestion of sucrose or glycine the results were so irregular with regard to time and magnitude of maximal response in the control period as well as following the administration of the various pituitary substances that conclusions regarding the effect of the latter on the specific dynamic action of food are unwarranted.—*J. B. Youmans.*

828. **MIYAGAWA, YONEJI, and KOHEI SAITO. On the biological significance of corpus luteum of ovary. An experimental study on the inner secretion of corpus luteum (corpus luteum hormone).** *Japanese Jour. Exp. Med.* 7(2): 145-156. 1929.—The authors observed changes characteristic of pregnancy in the genitalia and mammary

glands of albino rats and virgin guinea pigs after injections of corpora lutea of pregnancy. Injections of immature placental tissue produced the same results, whereas, the mature placenta, guinea pig embryos, uterine mucosa, ovarian follicular fluid, the interstitial gland of the ovary and the corpus luteum following menstruation were without effect. Injections of corpus luteum of pregnancy, moreover, produced changes in other glands (pituitary, thyroid, adrenals, pancreas) which were identical with those observed in pregnant controls. The authors conclude, therefore, that the substance capable of producing pregnancy changes in the genitalia and mammary glands is formed by the corpus luteum of pregnancy and not by the corpus luteum following menstruation. They call this substance the corpus luteum hormone. It is soluble in alcohol, ether, and water.—*H. C. Mack.*

829. MOORE, CARL R., and L. T. SAMUELS. The action of testis hormone in correcting changes induced in the rat prostate and seminal vesicles by vitamine B deficiency or partial inanition. *Amer. Jour. Physiol.* 96(2): 278-288. 5 fig. 1931.—The testes of 18 ♂ rats kept upon a diet deficient in the antineuritic fraction of vitamin B, or on insufficient diets containing an excess of B, were found to consist of normal seminiferous tubules in active spermatogenesis but the reproductive accessories (prostate gland and seminal vesicles) were castrate in type. In animals with castrate accessories daily injections of either testes hormone (10 rats) or anterior hypophysis hormone from pregnancy urine (4 rats) caused the castrate condition to be replaced by the normal state within 10 days. The authors interpret these findings in terms of a more general theory: Partial starvation induced by diets deficient in vitamin B, or insufficient diets rich in B, leads to a poor nutritive state which affects the hypophysis. Inhibition of hypophysial secretion leads to a lowered amount of the sex stimulating hormone available in the organism. In the absence of this stimulating substance the testes fail to continue their endocrine function and castrate accessories are present. Injections of testis hormone stimulate the accessories directly, whereas injections of hypophysis hormone stimulate the intact testes to secrete their hormone which then acts upon the accessories. There is evidence to show that under the conditions of the experiment the endocrine function of the testis is disturbed, whereas spermatogenetic function continues.

830. MORISHITA, HIDEO. Studies on the detoxicating hormone of the liver (Yakriton). 16th report. Prophylactic effect of Yakriton against ammonium carbonate convulsion. *Tohoku Jour. Exp. Med.* 14(2/3): 167-175. 1929.—Sato showed that "yakriton" detoxicated NH_4Cl when injected into rabbits. The author injected 3.1% solution of $(NH_4)_2CO_3$ intraperitoneally in a dose of 10 cc. per kgm. Rabbits varied greatly in sensitivity. Some showed convulsions within 5 min. and died, whereas others showed no apparent effect following injection of 4 times this dose. Subsequent injections of the same dose showed the same type of response. A dose of 30 units of Yakriton per kgm. subcutaneously prevented the development of convulsions after intraperitoneal injection of $(NH_4)_2CO_3$. Commercial $(NH_4)_2CO_3$ was found to be about 3 times as toxic as NH_4Cl.—*J. C. Munch.*

831. NEWTON, H. F., R. L. ZWEMER, and W. B. CANNON. Studies on the conditions of activity in endocrine organs. XXV. The mystery of emotional acceleration of the denervated heart after exclusion of known humoral accelerators. *Amer. Jour. Physiol.* 96 (2): 377-391. 1931.—Experiments yielding negative evidence are summarized: After complete denervation of the heart and exclusion of all known humoral cardio-accelerator agencies a momentary excitement and struggle will cause, in cats, a slow increase of the cardiac rate, reaching a maximum in about 3 min. and then slowly subsiding. Repeated struggles cause summation of effects on the heart rate. Full anesthesia (with ether, urethane or chloralose) greatly reduces and may abolish the phenomenon, i.e., stimulation of muscles and the sympathetic system under anesthesia does not produce the typical effect on the heart rate. Experiments are described which show that the phenomenon is not due to rise of arterial blood pressure, increase of temp., escape of adrenin from the denervated adrenal medulla or cortex, or from the liver, nor due to substances produced by the pancreas, gastro-intestinal mucosa, semilunar ganglia, pituitary body, gonads, thyroids, parathyroids, or active skeletal muscles. Transection of the thoracic spinal cord in the prepared cat leaves the fore part of the animal with the denervated heart, and the hind part with the denervated adrenal and liver, but with the lower abdominal sympathetic strands still intact. Struggle by the fore part of the animal is without effect; stimulation of the spinal cord in the lumbar region, causing muscular spasm and erection of the tail hairs, is followed by the typical slow rise and fall in the rate of the denervated heart. Obviously a substance is given off into the blood-stream by the hind part of the animal that affects the heart in the fore part. If all parts of the sympathetic system are disconnected from the spinal cord, except short ganglionated strands in the lower thorax, struggle causes the usual cardiac acceleration; but after the remnants of the system are excised, struggle no longer has that effect. This condition may last for many wks.

832. NICE, L. B., O. C. IRWIN, and RUTH M. KRAFT. Coagulation time of the blood of adrenalectomized rats. *Amer. Jour. Physiol.* 96(2): 305-307. 1931.—In 47 normal rats a well defined shortening in the time of coagulation (av. 47%) followed restraint and stimulation. The clotting time of the blood of the adrenalectomized rats after excitement was decreased in 15 determinations, increased in 5, and in 1 case unchanged. The average decrease for the group as a whole was 13%. The authors' results indicate that the adrenal glands are a large factor, but not the only one, responsible for the shortening of the coagulation time of the blood of emotionally excited rats.

833. NISHIMOTO, HIKOE. The change in the urinary constituents caused by the administration or removal of the thyroid gland. *Japanese Jour. Exp. Med.* 7(2): 225-239. 1929.—The author experimented with dogs. Nitrogenous substances, S compounds and certain other salts were determined quantitatively in the urine after administration of thyroid preparation in excessive quantities and after removal of the thyroid gland. Administration of thyroid preparation led to an increase in total N excretion, also a slight increase of ammonia and allantoin as compared with the quantity increase of amino acids, purine bases and uric acid. A marked increase of neutral S as well as Ca was observed. In the case of removal of the thyroid gland, the findings were reverse of those noted above.—*R. G. Turner.*

834. NOTHMANN, MARTIN. Nebenschilddrüsenhormon und Kalkstoffwechsel. *Klin. Wochenschr.* 8(23): 1068-1069. 1929.—Parathyroid extracts, prepared according to the directions of Collip, are yellow and are frequently slightly turbid. Such extracts have shown marked differences in their action when injected into different species of animals. The experiments described in this paper were carried out with a German preparation called Paratotol which is clear and colorless. This preparation elicits an identical reaction when injected into man, dogs, cats or rabbits. The Ca concentration in the blood is elevated to or above normal. The maximum concentration is attained in ½ to 1 hr. The blood Ca drops to its initial value after 3 hrs.—*M. Hanke.*

835. PADOA, EMANUELE. Caratteri legati al sesso nel piumaggio dei polli e inversione sessuale sperimentale. [Sexual characters of feathers in chickens, and experimental sexual inversion.] *Boll. Soc. Ital. Biol. Sperim.* 5(2): 86-90. 5 fig. 1930.—Three hens with black feathers from father Valdarno black, and mother Plymouth Rock, with barred feathers, were ovariectomised at the age of 3 mos., and developed masculine characters in feathers, form and disposition, comb, wattles, and spurs. In 1 case typical masculine behavior was

developed. No signs of barred feathers appeared. The form of feathers is due to hormonal factors (metabolic sex differences), whereas the sexual characters are based upon special genetic factors.—*M. Comel.*

836. **PARKES, A. S. On the synergism between oestrin and oxytocin.** *Jour. Physiol.* [*London*] 69(4): 463-472. 1930.—Pituitrin caused abortion or reabsorption in mice in doses of 1 unit or more: oxytocin, however, was practically without effect, even in doses of 5 units. The experimental finding that comparatively small amounts of vasopressin will terminate pregnancy apparently accounts for this discrepancy. It was not possible to cause abortion regularly by a single injection of "water-soluble" oestrin, but 380 units given in a series of injections over 36 hrs. usually produced abortion in 36-48 hrs. Although 260 units given in 13 injections over 12 hrs. failed to produce regular abortion, the administration of 1 or more units of oxytocin immediately after the last injection of oestrin caused almost immediate (1-6 hrs.) evacuation of the uterus. This reaction time is in marked contrast to that required (36-48 hrs.) for abortion following the injection of adequate amounts of oestrin. This result is in keeping with Bourne and Burn's report that oestrin will sensitize the uterus to the oxytocic principle of the posterior pituitary body. Oestrus recurs at varying intervals after induced abortion, but usually before it would have appeared if pregnancy had proceeded to term. The bearing of these results upon theories of the initiation of parturition is discussed.—*Author's summary.*

837. **PANIZZA, B. La determinazione sperimentale del sesso e la sterilità sessuale per via ormonica. [Experimental determination of sex, and hormonal sexual sterility.]** *Arch. di Fisiol.* 28(1): 51-68. 1 fig. 1930.—Homologous grafts of measured quantities of testicular tissue into the peritoneum of the guinea pig, if executed before fecundation, induce a decided predominance of female offspring. If the quantity of testicular tissue so grafted is above a certain value, there follows instead a deficient development of the fetus; probably ovarial lesions are caused, which are frequently followed by abortion, and more frequently, in the guinea pigs so treated, by sterility.—*M. Comel.*

Results of total and partial adrenalectomy and adrenal transplantation in the albino rat.** *Science* 72(1859): 175-176. 1930.—The rat is no exception to the rule that mammals cannot survive adrenalectomy. A very small piece of cortex remaining in situ can keep the animal alive indefinitely. Transplants of cortical material into an ovary have been successful, subsequent removal of this ovary brought on the usual train of insufficiency symptoms and death.—*J. M. D. Olmsted.*

840. **PENCIER, M. T. de, S. SOSKIN, and C. H. BEST. The effect of liver on the blood sugar level and on the sugar excretion of depancreatized dogs.** *Amer. Jour. Physiol.* 94(3): 548-552. 1930.—Ingestion of raw liver failed to lower the blood sugar or sugar excretion in 2 series of experiments on depancreatized dogs, or the blood sugar in a series of experiments on an unspecified number of normal dogs.

841. **PIAZZA, CESARE V. Valutazione biologica dell'attività dell'ormone emopoietico del fegato. [Biologic evaluation of the activity of the hemopoietic hormone of liver.]** *Boll. Soc. Ital. Biol. Sperim.* 5(3): 455-457. 1930.—When the hemopoietic substance (hormone) isolated by the author from liver is injected intraperitoneally in rabbits, an increase in reticulocytes of the blood follows. This increase is regarded as a biological test for evaluating the activity of the liver hormone.—*M. Comel.*

842. **POPOW, N. A., B. G. IWANOW, und A. A. KUDRJAWCEW. Zur Frage des Einflusses der Entfernung des Grosshirns bei Kücken auf das Wachstum.** *Pflüger's Arch. Ges. Physiol.* 225(5/6): 643-647. 3 fig. 1930.—In each of 7 pairs of chickens about 3 weeks old, the cerebrum was removed from 1 chicken; the general growth and growth of the thymus after 21-39 days showed distinct retardation in each of the decerebrate chickens as compared with the unoperated control; the thymus, indeed, was atrophied. Removal of the thymus from each of 5 older chickens also retarded growth as compared with the 5 unoperated controls.

843. **RABINOVITCH, JACOB. Changes in the thyroid gland of the guinea pig following a period of administration of potassium iodide.** *Amer. Jour. Pathol.* 6(1): 71-74. 1930.—Fifteen guinea pigs were fed 0.1 gm. KI daily for 15 days with resulting hyperplasia of the acinar epithelium of the thyroid gland, marked mitotic activity and softening of the colloid. These effects disappeared in the thyroids of those animals which were killed 3, 7 and more days after the last administration of KI.—*S. H. Gray.*

844. **RABINOVITCH, J., and S. H. GRAY. The effect of potassium iodide upon the thyroid gland of underfed guinea pigs.** *Amer. Jour. Pathol.* 6(1): 75-77. 1930.—Guinea pigs when fed KI usually show very definite signs of hyperplasia of the thyroid gland, especially as evidenced by an increased number of mitotic figures. In these experiments, however, it was found that when the animals are underfed, losing from 11% to 26% of their weight in 15 days, the stimulating effect of KI is missing. No hyperplasia occurs.—*S. H. Gray.*

845. **REGNIER, J., D. SANTENOISE, P. VARE, H. VERDIER, et M. VIDACOVITCH. Démonstration physiologique directe de l'existence d'une hormone thyroidienne régulatrice de l'excitabilité des centres psychomoteurs.** *Rev. Franç. Endocrin.* 8(1): 26-65. 1930.—The thyroid has two distinct relations to the nervous system, (1) It produces a substance which acts upon cerebral activity by lowering chronaxie of the psycho-motor centers; (2) on the other hand the production and excretion of this substance is dependent upon the action of the vagus. This substance appears to differ from thyroxine, the secretion and discharge of which is apparently independent of nerve control.—*B. Cunningham.*

846. **REYNOLDS, SAMUEL R. M., and M. H. FRIEDMAN. Studies on the uterus. III. The activity of the uterine fistula in unanesthetized rabbits following coitus and during pseudopregnancy. IV. The response of the uterine fistula of the unanesthetized rabbit to the injection of urine from pregnant women.** *Amer. Jour. Physiol.* 94(3): 696-704. 3 fig.; 705-707. 1930.—III. Female rabbits prior to coitus were seen to exhibit marked or moderate uterine activity. In 2 cases of 12, however, feeble activity preceding coitus was observed. During the 10 hr. period following coitus, and before the time of ovulation, the uterine activity became greatly decreased. The decrease in activity was seen about the 5th to the 8th hr., and was still more pronounced between the 9th to 12th hrs. post coitum. During the period of pseudopregnancy, the uterus remained relatively quiescent until about the 15th to the 20th day, when activity might return. The possible factors responsible for the initiation and maintenance of the quiescent condition of the uterus are considered. IV. The intravenous injection of urine from a pregnant woman into 10 ♀ rabbits regularly decreased the activity of the uterine fistula, while injection of urine from non-pregnant women into 5 ♀ rabbits left the activity of the uterine fistula quite unaltered or slightly increased it.

847. **RICHTER, CURT P., and GEORGE B. WISLOCKI. Anatomical and behavior changes produced in the rat by complete and partial extirpation of the pituitary gland.** *Amer. Jour. Physiol.* 95(2): 481-492. 1930.—The hypophysis was completely removed in 10

adult rats and partially removed in 15 adult animals, leaving intact either parts of the anterior lobe, or parts of both anterior and posterior lobes. The 10 animals with total removal of the glands were very inactive, as was determined by means of records of running activity in revolving drums. Spontaneous activity was not affected by partial removal of the gland. Body-weight and food-intake were definitely decreased by hypophysectomy. Usually they decreased to a low level, at which they remained fairly constant. The 4-day sex cycles were absent in the hypophysectomized animals, present and normal in the animals with only anterior lobe tissue remaining. In 3 animals, with both anterior and posterior lobe tissue present, the sex cycles were markedly disturbed. Permanent polydipsia was produced in a large fraction of the rats with the pituitary gland partially removed, but occurred in only 1 out of 10 animals with the gland totally extirpated. Further evidence has been gained that polydipsia does not depend on the removal of the pituitary gland. The variable and often transient increase in water-intake following complete or partial hypophysectomy is presumably due to the injury of the adjacent brain-stem. The magnitude of the increase is often the same as that characteristic of the increase produced by puncture of the neighboring tuber cinereum, but the increase is transient. Injections of alkaline extract of the pituitary gland following hypophysectomy produce a definite increase in body-weight and food-intake, but have no effect on spontaneous activity or water-intake. In completely hypophysectomized rats, autopsy reveals marked changes in other organs and tissues. The thyroids and adrenals are hypoplastic. The reproductive organs are markedly enlarged. The thymus and the lymph-glands of the entire body are markedly enlarged. There is a pronounced disappearance of body fat. These changes can be obtained in a mild degree, in some instances, after incomplete removal of the pituitary.—*Authors' summary.*

848. SANTENOISE, D., H. VERDIER, et M. VIDACOVITCH. Isolement d'une nouvelle hormone pancréatique, régulatrice de l'activité vagale. [Isolation of a new vagus regulating hormone from the pancreas.] *Rev. Franc. Endocrin.* 8(3): 204-260. 1930.—The authors have separated from pancreatic extract by alcohols and neutral salts two substances, one not at all vagotonic but producing hypoglycemia, the other strongly vagotonic. They conclude therefore that the pancreas secretes 2 hormones, the second of which reacts on the vagus, and which they propose to call vagotonine.—*B. Cunningham.*

849. SATAKE, YASUTARO, and TAIZO KUMAGAI. On diabetes mellitus. *Ann. Rept. of Work* (*Saito Ho-on Kai*) [*Sendai*] No. 4: 56-59. 1927(1929).—A report of work by various investigators. TAKEUCHI has estimated the content of hormone per gm. of pancreas in several animals. In descending order of content, these are: dog, horse, pig, ox, man, and cat. In general, the hormone content for the body weight is greatest for the carnivora and least for the herbivora. KOZUKA found that blood fructose as well as glucose is decreased by the pancreatic hormone. SATO found that the liver glycogen is increased on repeated administration of small doses of the hormone, whereas the glycogen content of skeletal muscle and of lymph from the thoracic duct were always diminished. The glucose content of lymph could not be reduced below the carotid blood level. The hormone augments the difference between blood sugar values for femoral vein and femoral artery; the difference between the values for carotid artery and jugular vein is unchanged. Glucose consumption in the isolated heart is also increased several times by the hormone. SUGAWARA and TADA observed that the simultaneous injection of adrenalin chloride and guanidine hydrochloride into doubly splanchnicotomized dogs gave the same effect on blood sugar that was obtained when the two substances were injected separately.—*F. Hollander.*

850. SCHOUPPÉ, KARL. Beitrag zur hormonalen Beeinflussung des Geschlechtes. *Arch. Wiss. u. Prakt. Tierheilk.* 62(3): 267-270. 1930.—Hens fed with 1 gm. testis every 2-3 days for 3 weeks produced sterile eggs. The temporary sterility can be quickly reversed by administering ovarian hormones. Feeding with ovaries appears to influence sex, since the chicks produced were all ♀. In dogs sex cannot be influenced after conception, even with the feeding of large quantities of hormones.—*K. Schouppé* (*transl. by R. A. Mutthowski*).

851. SCHOUPPÉ, KARL. Beitrag zur Frage des Antagonismus der weiblichen und männlichen Keimdrüsen. *Wiener Tierärztl. Monatsschr.* 17(15): 565-573. 1930.—From the literature it is evident that similar sexual hormones promote, while opposing ones retard formation of gonads. Weise alone observed opposite action from administration of antagonistic hormones. He made his investigations on cattle. If further investigations confirm his findings, therapeutics will be enriched with a new method of treatment, namely, the "hormone stimulant therapy" using antagonistic hormones. By feeding testicular extract to a nymphomaniac mare, the abnormality was corrected. Through feeding testes to a sow, prevention of oestrum, alterations of the uterus such as loss of tone, shrinking of the bands and sterility could be observed.—*K. Schouppé* (*transl. by R. B. Becker*).

855. SHPINER, LEONARD BENJAMIN. Increased metabolism only one factor in the production and maintenance of the hyperglycemia and glycosuria in experimental hyperthyroidism. *Amer. Jour. Physiol.* 92(3): 672-678. 1930.—Large doses of thyroid extract do not produce a hyperglycemia and glycosuria in normal dogs. However, in the series of 6 dogs which have had the major portion of their pancreas removed (19/20) with the factor of safety reduced to a minimum, it was effective in the production of a permanent hyperglycemia and glycosuria (diabetes). The greater hyperpyrexia which accompanies the subcutaneous injection of sodium nucleinate produces a mild hyperglycemia and glycosuria in normal dogs. In the series of 4 partially pancreatectomized dogs sodium nucleinate did not cause as marked and persistent a hyperglycemia and glycosuria as did thyroid feeding. The influence of the thyroid seems to be not solely through its effect on basal metabolism, but possibly through some toxic effect of thyroxin exerted on the islet tissue of the pancreas. In this sense (toxic action of the thyroid hormone), one might speak of an antagonism between the pancreas and the thyroid.—*Author's summary and conclusions.*

856. SIEGMUND, HERMANN. Über die Abhängigkeit des Uterus von den Funktionsphasen des Ovariums. (Tierexperimentelle Untersuchungen.) III. Der Einfluss von Prolan auf die Ovarien und deren Erfolgsorgane. *Arch. Gynäkol.* 142(3): 702-729. 20 fig. 1930.—To investigate whether corpus luteum hormone can be formed in prematurely developed ovaries, the functional behavior of the uterine musculature during development

and functional phases of the ovary has been observed. A difference in reaction is shown by the rat and rabbit uterus. During duration of functional corpora lutea, rabbit uterus suffers a regular intermittent loss of tonus and contractility, not influenced by administration of posterior lobe secretion. This phenomenon is entirely lacking in the rat and there is no antagonism between the posterior lobe of the hypophysis and the corpus luteum in their action on the uterine muscle. The unequal reaction of the uteri of these rodents is unchanged during pregnancy. This difference illustrates the varying reactions of like organs of different mammals to the hormones of similar endocrine glands. Experiments with active corpus luteum extracts show that the difference in reaction of uteri of different mammals at the time of the functioning corpus luteum is not due to a difference in its secretion. In the rat, the sterile horn of the uterus at the end of pregnancy is 2-3 times normal weight while the empty pregnant horn is 20-30 times normal—due to muscular increase which is due to different control of the two horns. The pregnant horn is supplied ovarian hormones in two ways—direct from the chorionic villi and by way of the blood stream. This double supply accounts for the great increase in weight of the pregnant horn. The more deep seated ova thus are caused to act as hormone producing centers in direct liquid connection with the pregnant horn. The biological function of the corpus luteum hormone is due to the young corpus-luteum-like structure. In the rabbit this is clearly related to the functional behavior of the uterine musculature, the development of the uterine endometrium and the proliferation of the mammary parenchyma. In the prematurely developed ovary, corpus luteum and follicular hormones can both be formed but at different stages of developemnt of the organism. Follicular hormone is easily demonstrable in treated ovaries of very young animals while corpus luteum hormone cannot be shown to exist until later. Animals treated with Prolan are not completely matured and the effect quickly disappears. The nearer the animal is to puberty, the more rapidly can the puberty be attained. The gradual development of the organism seems to depend, in an inverse ratio, on the degree of development of the body and the needed amount of the hormone.—*L. Levin.*

857. SMITH, GEORGE VAN S., and O. WATKINS. A biochemical investigation into the function of corpus luteum. A study of blood sugar and non-protein nitrogen changes in rabbits after the administration of corpus luteum. *Amer. Jour. Physiol.* 94(3): 586-596. 1930.—Intraperitoneal injections of the Corner and Allen lipid extract of corpus luteum were given to rabbits (normal non-pregnant, pregnant, lactating and spayed does, and normal bucks) and resulted at certain times in marked physical reactions accompanied by rises in the sugar and non-protein N of the blood. Control experiments demonstrated that these reactions were specific for the active corpus luteum principle of the extracts used. In most cases, non-pregnant doe rabbits, pregnant rabbits after the 4th day of gestation and lactating rabbits after the 6th day postpartum gave no physical or biochemical evidence of responding to the injections. Occasionally, however, marked typical reactions occurred. No correlation could be made between such reactions and the known physiological state of the animals. Normal doe rabbits always react typically to injection any time from 34 hrs. to 4 days after copulation. The ovaries at this time show ruptured follicles. If the animal is spayed after being served the reaction does not follow injection. From 24 hrs. to 6 days after delivery normal does give positive reactions to the injection of corpus luteum. The post-delivery ovaries show no evidence of ruptured follicles and removal of them does not prevent the reaction. Removal of the uterus has no effect upon the response to corpus luteum either in early pregnancy or after delivery. Spayed does and normal bucks rarely show any physical or biochemical changes following intraperitoneal injection of corpus luteum, but if these unreactive animals are first brought under the influence of folliculin, the corpus luteum injection always induces a positive reaction. This finding indicates that the consistent reactions of does after copulation and the occasional reactions of non-pregnant and pregnant does are the result of the normal production of folliculin within the organism. This biochemical evidence confirms the findings of Hisaw and of Allen of an interrelationship between corpus luteum and the oestrus hormone. The behavior of lactating does, however, cannot be explained upon this basis and the possible influence of the sex principle of the anterior pituitary has not been eliminated. The rise in non-protein N is almost entirely accounted for by a rise of urea. Although this points to renal upset, the direct poisoning of the kidneys by lithium urate does not give comparable sugar and urea curves. Intraperitoneal injection of epinephrine, on the other hand, results in both non-protein N and sugar rises practically identical, in magnitude and time relations, to those following a positive corpus luteum reaction. This suggests that the corpus luteum under certain physiological conditions either stimulates the sympathetic nervous system or else has a direct effect upon the organism similar to that of the adrenal medulla. Whether or not the urea rise is a secondary result and possibly due to kidney damage has not yet been ascertained. It seems possible that the biochemical changes following injection of single large doses of corpus luteum extract may be an exaggeration of a normal catabolic action of this gland. This effect would be entirely in keeping with the importance of the corpus luteum for the implantation and nourishment of the ovum.—*Authors' summary.*

858. SMITH, PHILIP E., and E. C. MacDOWELL. An hereditary anterior-pituitary deficiency in the mouse. *Anat. Rec.* 46(3): 249-257. 3 fig. 1930.—A preliminary report is given upon the disabilities in hereditary dwarfism appearing in a strain of silver mice being reared by MacDowell at Cold Spring Harbor. The dwarfism appears abruptly at about the 15th day of life. The dwarfs remain sterile. Thyroids, adrenals, and reproductive organs exhibit, in a lesser degree, the same structural abnormalities as described by one of us in hypophysectomized rats. The posterior lobe of the pituitary appears to be normal; the anterior lobe contains no typical eosinophiles and is largely composed of connective tissue. No definite conclusions have been drawn regarding the presence or absence of basophiles. Chromophobes, though possibly present, are greatly reduced in number. Daily anterior-pituitary implants have been given to 6 dwarfs. These induced a normal rate of general body growth, although the great difference in size between the dwarfs and normals at the beginning of treatment has not been entirely overcome. The implants induce growth of the reproductive organs and bring the thyroids and adrenals to a normal condition. Thirty young sired by a treated dwarf male have been born. The anterior pituitary alone, of the endocrine glands, is not repaired. It is concluded that dwarfism and associated abnormalities appearing in this strain of mice are due to a deficiency of the anterior pituitary, which is inherited in an alternative manner.—*Author (courtesy Wistar Bibl. Serv.).*

859. SODA, G. Follikulin und Oxydation. *Zentralbl. Gynäkol.* 54(4): 215-219. 1930.—Using the oxidation quotient of the urine method of von Helmut Müller, Soda tested the effects of injecting from 10 to 80 rat units of folliculin into normal and castrated female rats. The injections did not cause any noteworthy change in the average oxidation quotient of the urine and it is concluded that folliculin does not produce in these animals any changes in oxidation.—*G. L. Kelly.*

862. **STEINACH, E., und H. KUN.** Die Inkretion der männlichen Keimdrüse und ihre Abhängigkeit vom Vorderlappen-Hormon. Versuche an Infantilen, Eunuchoiden und Senilen. *Akad. Wiss. Wien. Mat. Nat. Kl. Anz.* 65 (1/27): 39-44; 51-58. 1928.—Infantile male rats of 4 to 5 weeks were injected with 0.2-0.3 cc. of water extract of the anterior lobe of cattle. 0.3 cc. corresponded to about ¼ of the anterior lobe substance. In some the testes descended in 6 days. In 10 to 12 days the prostates and seminal vesicles were fully developed and filled with secretion. Coitus took place at this time, 38 to 45 days, whereas normal males do not mate until 95 to 100 days. Five days after injections were stopped libido and potency disappeared, and laparotomies showed considerable decrease in size of the seminal vesicles and prostate. The most striking change in the testes was a great increase in apparent activity and amount of interstitial tissue over that of controls. No mention is made of sperm or of fertility. Eunuchoid rats became anatomically and psychically like normal males after 14 to 21 injections of 0.4-0.6 cc. of the extract. Active spermatozoa occurred in their ejaculates. Cessation of treatment for 2 weeks caused resumption of the eunuchoid condition. Further injections renewed normalcy. Three 19 to 24 mos. old senile bucks became active males after 12 to 18 injections. Microscopic examination showed a great increase in interstitial cells. Cessation of treatment resulted in senility again. It is concluded that embryonic development of the reproductive tract is furthered by the anterior lobe hormone of the mother acting through the stimulated fetal gonadal secretions. At birth a pause occurs until near puberty when the individual's anterior lobe becomes active and stimulates the production of internal secretion by the gonads. Normal sexual function is maintained throughout life by the interaction of the pituitary and gonads. Waning activity of the pituitary causes inactivity of the gonadal secretion and hence senility.—*H. W. Mossman.*

863. **[STEPPUN, O. A., and K. D. SARGIN.]** СТЕППУН, О. А., и К. Д. САРГИН. О действии экстрактов органов на периферический эффект адреналина. **[Modification of the peripheral activity of adrenalin by extracts of various organs.]** [German summary.] Труды Научного Химико-Фармацевтического Института (*Trans. Sci. Chem. Pharmaceut. Inst. [Moscow]*) 13: 63-79. 1926.—Based on the well-known fact that hypophysis extract synergizes the vasoconstrictor action of epinephrine, and from the fact reported by the author that placenta extract reinforces the action of hypophysis extract on surviving uterus, the question of whether placenta extract also influences epinephrine action was investigated. Such an effect was actually obtained. Other organ extracts gave similar but much weaker effects. It is concluded that active placenta substance potentiates hypophysis action, and that hypophysis potentiates epinephrine action. The placenta influences epinephrine action directly or through the hypophysis.—*From authors' summary.*

864. **STSCHEDROWITZKY, S. G., A. S. STSCHEDROWITZKY, und S. A. SELTZER.** Über funktionelle Beeinflussung der Schilddrüse durch einige Nährstoffe. (Experimentelle Untersuchung.) *Zeitschr. Ges. Exp. Med.* 72(5/6): 699-702. 3 fig. 1930.—The results of Sternberg's serum-atropin reaction on 11 dogs (9 normal, 1 thyroidectomized, and 1 with natural struma) given successively mixed (milk, meat, fat), meat, milk and fat diet are given. This dietary series was repeated 7-9 times for each dog, making a total of 82 experiments. The conclusions, so far as justified by the serum-atropin reaction, are that meat diet stimulates, milk diet depresses the thyroid function; fat diet is without effect, and no diet affects the serum-atropin reaction after thyroidectomy.

865. **SWINGLE, W. W., and J. J. PFIFFNER.** Studies on the adrenal cortex. I. The effect of a lipid fraction upon the life-span of adrenalectomized cats. II. An aqueous extract of the adrenal cortex which maintains the life of bilaterally adrenalectomized cats. III. The revival of cats prostrate from adrenal insufficiency with an aqueous extract of the cortex. *Amer. Jour. Physiol.* 96(1): 153-163; 164-179; 180-190. 1931.—I. The survival period of 38 untreated control suprarenalectomized cats was 4-15 days (av. 7.7 days). The survival period of 23 double suprarenalectomized cats treated with a crude lipid fraction of beef suprarenal cortex, obtained by alcoholic-benzene extraction, was 16-60 days (av. 27.8 days). The behavior of the extract-treated animals was normal up to the abrupt appearance of suprarenal insufficiency symptoms a few days before death. The primary object of the study was the conclusive demonstration of the presence of the cortical hormone in the crude lipid fraction. The cortical hormone is stable in ethyl alcohol for a period of at least 2 wks., and the crude lipid fraction when prepared in oil retains its potency for about 3 wks. when kept at 6° C. The active lipid fraction is not epinephrine free. In so far as the authors are aware this is the first conclusive demonstration that the hormone of the suprarenal cortex which is essential for the maintenance of life can be extracted with lipid solvents. II. The effect of various fractions of the crude lipid extract of beef suprarenals was tested on 32 double-suprarenalectomized cats. The acetone-soluble fraction was highly active; all 5 cats tested as long as the extract was continued (30-50 days). It contains the cortical hormone but presents serious difficulties of administration (formation of lumps and sloughs at site of injection). The acetone-insoluble fraction did not prolong the life of the 3 suprarenalectomized cats on which it was used; it seems inactive. Of 5 cats on which the petroleum-ether-soluble fraction was tested, 2, which received the fraction following a single distribution between petroleum-ether and 70% alcohol, survived 22 and 19 days respectively; the 3 others, which received a fraction obtained after 4 distributions, survived 4.8 days, indicating that after 4 distributions the petroleum-ether fraction is inactive. Of 19 suprarenalectomized cats treated with the alcohol-soluble fraction obtained after distribution between petroleum-ether and 70% alcohol, all lived in good health throughout the arbitrarily selected 100-day treatment period and died with symptoms of suprarenal insufficiency on cessation of treatment, except 3 killed at the end of 50 days and 4 which died of pneumonia, generalized infections or fits. Hence this extract contains the "cortical hormone" or hormone of the suprarenal cortex. This aqueous extract is protein-free but not epinephrine free, containing an average of about 0.4% of the epinephrine present in fresh cortical substance. Potent extracts have been prepared from adrenal cortex stored in alcohol at room temp. for periods of 2-3 wks. No deterioration in activity was observed in active fractions stored in alcohol or benzene at 8° C. from 4-6 wks. Active fractions can be safely stored in acetone for several days. The authors' tests indicate that there is no loss of activity in aqueous extracts in 7-14 days when stored at 8° C. without a preservative. III. For use on cats near death from suprarenal insufficiency a potent "cortical extract" practically free from epinephrine was required. A method is described for the preparation of extract containing about 1:2,000,000 suprarenalin and potent enough to restore suprarenalectomized cats repeatedly to normal.

866. **SZARKA, A.** Einfluss des Ovarialzyklus auf die spezifisch-dynamische Wirkung der Nahrungsstoffe. *Pflüger's Arch. Ges. Physiol.* 225(5/6): 620-626. 3 fig. 1930.—The study was made on 3 sexually mature ♀ white rats, 16, 14 and 17 experiments respectively. The food was 60% protein and 40% carbohydrate. The specific-dynamic action varied according to the oestrual cycle; it was highest at the time of the lowest basal metabolism

values, i.e., in meta-oestrus. The lowest specific-dynamic action was 6.5% of the basal metabolism, the highest 35.8%.

867. **SZENT-GYÖRGYI, ALBERT. On the mechanism of biological oxidation and the function of the suprarenal gland.** *Science* 72(1857): 125-126. 1930.—There are 4 specific substances elaborated by the whole suprarenal gland. In the medulla are found epinephrine and a strongly reducing substance. In the cortex are found hexuronic acid and apparently another principle, the existence of which seems established by the recent work of Hartman and his collaborators, of Stewart and Rogoff and by the most recent investigation of Swingle.

868. **TAKAHASHI, SHIRO. Der Einfluss der Präparation der Hinterlappen der Hypophyse auf die Sekretion der Milchdrüse.** [Japanese.] [Effect of preparation of the posterior lobe of the hypophysis on milk secretion.] *Kyoto Igaku Zasshi* 24(5): 495-515. 1927.—After administration the milk in the alveoli and the excretory ducts increased and the smooth muscle fibers of the stroma were contracted.—*O. Mori (courtesy Japanese Jour. Zool.) (transl. by C. W. Turner).*

869. **TOURNADE. Splanchnique et surrénale. La splanchnique est-il nerf adrénalino-sécréteur ou excréteur?** *Bull. Acad. Roy. Méd. Belgique* 9(4): 160-186. 1929.—The hyperadrenalinemia after excitation of the splanchnic can be produced by secretion, excretion or by mechanical injuries to gland during the operation. Popielski thinks that in all former experiments technical errors were made. The adrenal gland however reacts not only on the first excitation of the splanchnic, but also on repeated excitations, where the possibility of mechanical lesions is greatly diminished. The opinion that mere tractions of the nerve can produce some mechanical effect is refuted by the author in experiments on parabiotically connected dogs. The opinion of Pearlman and Vincent, according to which the effect of splanchnic excitation is due to vasomotor changes, cannot be considered correct. Gley and Quinquad propose the excretion theory, as the effect of the splanchnic excitation is of short duration and the gland is quickly exhausted. The author ascertained by his experiments that faradization of the splanchnic lasting a long time causes also a production of adrenaline for a long time. If it is an excretion it must be compensated for by equal secretion. If short excitations are repeated the effect remains the same, as long as the nerve remains intact. It is not therefore a question of quick exhaustion. The splanchnic is therefore a true secretory nerve for the adrenal medulla.—*E. Polák.*

870. **UBANEK, JOSEF. Ueber die Schwangerschaftsveränderungen der Hypophyse und ihren Einfluss auf das Gesichtsfeld.** *Wien. Klin. Wochenschr.* 40(38): 1195-1198. 6 fig. 1927.—40 pregnant women were studied during the last weeks of pregnancy. In no cases did the author find a narrowing of the temporal visual field that exceeded normal physiological limits. In a few cases the visual field for color was slightly narrowed concentrically, but never in the sense of a bitemporal hemianopsia. In certain pre-eclamptic cases a temporal narrowing of the field for blue was noted. The author concludes that normal pregnancy has no direct effect upon the visual field. Other factors which sometimes accompany pregnancy, such as disturbed liver or kidney function, may produce disturbances of light or color sense.—*W. J. Atwell.*

871. **URBACH, ERICH. Endokrin bedingte Haut-, Schleimhaut- und Haarerkrankungen.** *Arch. Dermatol. u. Syph.* 161(3): 492-503. 9 fig. 1930.—Reports of 12 cases (10 ♀, 2 ♂), in all of which falling of the hair, and in most of which eczema, was prominent; 10 of the cases were relieved by ovarian or thyroid preparation, or irradiation of the hypophysis; the 2 others were not treated for lack of a suitable hormone preparation.

872. **VACEK, T. Studie o rušení adrenalinu. 5. Význam kyselin o rûzném stupni dissocice při fotooxydaci adrenalinu. [On destruction of adrenalin. 5. Effect of H-ion concentration and various acids on photooxidation of adrenalin.]** *Biol. Spisy Vysoké Školy Zvěrolékařské Brno (Publ. Biol. École Haut. Études Vét. Brno)* 7(27)-(33). 1928.—Four commercial adrenalin preparations were oxidized by ultraviolet or visible rays. The former oxidize adrenalin at a higher rate. Adrenalin was dissolved in four different acids. The smallest difference between the efficacy of ultraviolet and visible rays was found when adrenalin was dissolved in HCl. The rate of oxidation was not proportional to the degree of dissociation of the acids; it was slowest in lactic acid. When dissolved in the same acid of different normality, oxidation was indirectly proportional to the H-ion concentration of the solution.—*Author's German summary (transl. by G. T. Cori).*

873. **VELHAGEN, KARL, jun. Über die antagonistischen Beziehungen zwischen Hinterlappenhormonen und Insulin.** *Arch. Exp. Path. u. Pharmakol.* 142(3/4): 127-138. 7 fig. 1929.—Most of the experiments were made on rabbits (number not stated). Extracts of the pars neuralis as well as of the pars intermedia, given at intervals of at least a week to the same animals, raised the blood-sugar, and antagonized insulin, showing that this action of the posterior lobe is due to a substance contained in both parts. Large doses of posterior lobe were required; 50 mgm. of pars intermedia or pars neuralis diminished the action of 6 units of insulin in a rabbit weighing 1.9 kgm., but did not completely suppress hypoglycemia. Larger doses of insulin could scarcely be neutralized; 35 units of insulin had a distinct blood-sugar-lowering effect in spite of preliminary administration of 900 mgm. pars neuralis. A "large series" of rabbits treated with "enormous" quantities of posterior lobe extract (as much as 3.19 gm. neuralis tissue in 48 hrs.) exhibited only a transient hyperglycemia, indicating that (contrary to the views of some other investigators) the lack of posterior lobe secretion cannot cause increase in sensitiveness to insulin, and that hypophyseal glycosuria cannot be due to inhibition of insulin action by increased posterior lobe secretion. Injection of 1 cat and 2 dogs (all with pancreatic diabetes) with extract of posterior lobe, altogether 2000 mgm. fresh posterior lobe substance, in hourly amounts of 100 mgm., produced no secondary hypoglycemia. The conclusion is that the secondary fall in blood-sugar observed in normal animals after such injection is the result of increased insulin secretion. Experiments on the isolated uterus of the rat and on decapitated cats indicated that insulin is not an antagonist of the blood-pressure-raising and uterus-stimulating substance of the posterior lobe.

876. **VOGELER, KARL. Über die Abhängigkeit der Funktion der Schilddrüse vom Lebensalter und von krankhaften Zuständen.** *Arch. Klin. Chir.* 157(Kongressber.): 704-717. 9 fig. 1929.—Normal human thyroids obtained at necropsy were dried and powdered. The minimal amount which would influence the development of tadpoles was determined. The tadpoles were fed on calf's heart, the thyroid powder was added to the water only once and the animals observed for 2 weeks. The material present in the thyroid which influences tadpole development was found to vary with age. The embryonic thyroid at the 6th mo. contained

little of it; then followed a rise until birth, then a fall for 1 mo., then again a rise; between the 1st and 12th year the amount showed little change; between the 12th and 15th year there occurred a marked increase. From then on until the 80th year the amount showed little variation in males. In female thyroids the amount of active material was higher, but at the age of 40 a drop below the male level occurred. After 50 the female thyroid contained again more active material than the male thyroid.—*G. T. Cori.*

877. **WATRIN, J. L'hémocrinie hypophysaire.** *Rev. Franç. Endocrin.* 8(3): 193-203. 6 fig. 1930.—Injections and transplantations show that the anterior pituitary has to do directly with gonadal development, producing precocious development of gonadal accessory structures as well. Transplants increased size, secretion and congestion in thyroid and pituitary.—*B. Cunningham.*

878. **WYMAN, LELAND C., and CAROLINE tum SUDEN. Studies on suprarenal insufficiency. VIII. The blood volume of the rat in suprarenal insufficiency, anaphylactic shock and histamine shock.** *Amer. Jour. Physiol.* 94(3): 579-585. 1930.—In 23 normal rats the % of plasma of the blood was from 51.7 to 60.7, averaging 56.3%. The blood was from 6.6 to 9.6% of the body weight, averaging 7.6%. Following a control blank operation blood volume determinations were within the normal range. In suprarenalectomized rats having autoplastic cortical transplants but no demonstrable chromaffin tissue blood volume determinations were also within the normal range. In suprarenalectomized rats having gross accessory cortical tissue and before the appearance of severe symptoms in those which died later of insufficiency the blood volume showed only normal fluctuations. After severe symptoms of suprarenal insufficiency had appeared or during the final stages of insufficiency there was a reduction in the blood volume, due chiefly to a reduction in plasma. Anaphylactic shock in sensitized rats was accompanied by a reduction in the volume of the blood plasma, the amount of reduction being correlated with the severity of the shock. Histamine poisoning in rats was accompanied by a reduction in plasma volume, the amount of reduction being roughly correlated with size of dose and severity of symptoms, being marked in some instances. It is suggested that inability to maintain capillary tone and normal permeability, probably due to lack of medullary suprarenal secretion, resulting in reduction of plasma volume, is the chief factor in increased susceptibility of suprarenalectomized rats to anaphylactic and histamine shock.—*Authors' summary.*

In roosters there is noticeable shrinkage of the testicles. In hens there is degeneration and malformation of the follicles interfering with egg-laying.—*Author's summary (transl. by R. G. Turner).*

882. **ZUNZ, EDGARD, et JEAN La BARRE. Contributions à l'étude des variations physiologiques de la sécrétion interne du pancréas. VIII. Répercussion de l'activité exocrine du pancréas sur l'insuline-sécrétion.** *Arch. Internat. Physiol.* 33(2): 142-158. 1930.—Dilute HCl (0.5-0.8%) was introduced into the duodenum in 5 adrenalectomized and chloralosed dogs, and physiologic solution into the duodenum in 2 controls. In 3 of the adrenalectomized dogs a copious secretion of pancreatic juice (9.2-16.8 cc.) and a marked fall in blood sugar followed; in the 2 others the pancreatic secretion was 2.5 and 4.5 cc. and the blood sugar rose slightly, as it did in the 2 controls, in which there was no secretion of pancreatic juice. The fact that unless the suprarenal capsules are removed or ligated, introduction of HCl into the intestine (even when followed by profuse secretion of pancreatic juice) is followed by hyperglycemia instead of hypoglycemia, is additional evidence for the compensatory hyperadrenalinemia by which the organism reacts to all increase in blood sugar. To study the action of HCl in the duodenum on secretion of insulin, 12 dogs were arranged in 6 pairs for transfusion; 1 animal in each pair, after receiving weak HCl intraduodenally as above, served as donor of blood from the principal pancreatic vein, which the partner received in the jugular vein. The donors in 2 other (control) pairs received physiologic solution. In 4 of the dogs receiving HCl abundant secretion of pancreatic juice followed; in the recipient partners the blood sugar fell to 20.95-32.73% of its initial value by the end of 3 hrs., while the donors also showed a slight and transient fall in blood sugar. In the other 2 HCl dogs there was little flow of pancreatic juice, and little variation in blood sugar (slight increase in 1 case). Physiologic solution produced no flow of pancreatic juice and no significant change in blood sugar in either donor or recipient. In 3 dogs subjected to double subcardiac vagotomy after chloralose anesthesia and suprarenalectomy, the same correlation between flow of pancreatic juice and fall in blood sugar was observed.

884. **ABE, M. Investigation of placental ferments in various stages of pregnancy. I. Lipase of placenta.** *Japanese Jour. Obstetr. & Gynecol.* 13(3): 301-303. 1930.—The quantity of lipase was determined in 56 fresh human placentas, from the stage of incomplete formation in the 2nd mo. to the 10th mo. The production of lipase was demonstrated at every stage of pregnancy, the quantity not varying widely, but somewhat greater in

the 4th, 5th and 6th mos. The placental lipase demonstrated in these experiments has an intense sensitivity toward atoxyl and cocaine, but is affected very slightly by quinine and strychnine.

885. **ANKEL, W. E. Neuere Untersuchungen über Parthenogenese bei Schmetterlingen.** *Internat. Ent. Zeitschr.* 22(28): 259-264; (29): 265-271; (31): 288-291. 1928.—A general discussion of parthenogenesis in the animal kingdom, referring particularly to natural parthenogenesis and to the Insecta. The occurrence of this phenomenon in the various phyla and its biological significance in the various cases are briefly considered. The literature on parthenogenesis in the Lepidoptera is reviewed in detail, with extensive comment on Seiler's contributions (1923).

886. **ANSELMINO, KARL JULIUS, und FRIEDRICH HOFFMANN. Über den Milchsäureumsatz in der Schwangerschaft und seine Beziehungen zum Kohlehydratstoffwechsel, zur Leber- und Schilddrüsenfunktion und zum Kreislauf. I. Woher stammt die Milchsäureerhöhung im Blut von Schwangeren?** *Arch. Gynaekol.* 142(2): 289-309. 4 fig. 1930.—Injections of lactic acid in varying amounts were given to 6 pregnant and 2 non-pregnant women, and the lactic acid of the blood determined at varying intervals thereafter. The pregnant subjects showed no appreciable difference from the non-pregnant, and consequently no derangement of hepatic function. The increase in muscle lactic acid after muscular exertion was decidedly greater in 15 pregnant than in 7 non-pregnant women. The increase, however, was confined to the muscularly active portion of the body, an indication that the liver of pregnancy not only injects lactic acid into the blood but promptly removes lactic acid produced under physiologic conditions. Similar results were obtained in 2 determinations in the puerperium, 5 determinations on pregnant women under different conditions, and in 2 cases in which determinations were made before and after parturition. The conclusion is that the theory of increased lactic acid output by the liver in pregnancy is erroneous, and that the increase in output is due to the muscle.

887. **ASHBEL, RIVKA. Sulla viscosità delle uova fecondate e non fecondate di ricci di mare (Arbacia pustulosa). [On the viscosity of eggs of sea urchin—Arbacia pustulosa—before and after fertilization.]** *Boll. Soc. Ital. Biol. Sperim.* 5(2): 70-72. 1930.—Viscosity of eggs of the sea urchin is increased after fertilization. Non-fertilized eggs are much more resistant to dislocations caused by centrifugation. To treatment with CO_2(pH = 5.9 to 5.6) the fertilized eggs, on the contrary, are more resistant, as also when the eggs are placed in a mixture of sea water, CO_2 and propyl alcohol (8 to 12%). In the non-fertilized eggs cytolysis and agglutination are therein observed. KCN does not influence the viscosity of non-fertilized eggs, whereas dislocation takes place in the fecundated eggs. These latter rarely show cytolysis when treated with a mixture of CO_2, alcohol and KCN; the non-fertilized always show it and the cytolysis is followed by agglutination of the pigment granules.—*M. Comel.*

888. **ASHBEL, RIVKA. Sul quoziente respiratorio delle uova fecondate e non fecondate dei ricci di mare —Arbacia putulosa Gray.—[On the respiratory quotient of fertilized and non-fertilized eggs of the sea urchin, A. pustulosa.]** *Boll. Soc. Ital. Biol. Sperim.* 5(2): 72-74. 1930.—The R. Q. of the sea urchin eggs decreases immediately after fertilization. Average of 18 experiments: R. Q. of non fecundated eggs 1.06, of the fertilized 0.95.—*M. Comel.*

889. **BACQ, Z. M. Impotence of the male rodent after sympathetic denervation of the genital organs.** *Amer. Jour. Physiol.* 96(2): 321-330. 1931.—Bilateral abdominal sympathectomy induced permanent impotence in 2 young rats; the same result was obtained in another after unilateral sympathectomy. Temporary impotence was observed after bilateral abdominal sympathectomy in 2 guinea pigs. Permanent impotence was recorded in another one after removal of the hypogastric nerves and inferior mesenteric ganglion. This difference is due to the regeneration of the preganglionic fibres. Remarkable enlargement of the denervated seminal vesicles was observed in the guinea pig. No atrophy whatsoever could be detected in the testes of the impotent rats. No persistent erection was observed after sympathetic denervation of the internal genital organs. Bacq concludes that the presence of the sympathetic nerve supply to the ♂ genital organs is necessary for ejaculation and consequently for reproduction.—*From author's summary.*

890. **BENAZZI, MARIO. Sull'origine del pigmento nell'utero di Mus musculus. [On the origin of pigment in the uterus of Mus musculus.]** *Boll. Soc. Ital. Biol. Sperim.* 5(3): 336-338. 1930.—The origin and meaning of the pigment in the mesometrium of uterus of mice do not pertain to pregnancy. The formation of pigment is on the contrary related to the puerperium.—*M. Comel.*

891. **BREMICKER, WERNER. Vergleichende Studien über die Biologie der Vagina.** *Arch. Gynäkol.* 129(3): 807-843. 1926-1927.—The greatest percentage of animals show changes in the vagina on account of intercourse only at the time of heat or shortly thereafter. In a large percentage, the vagina is lined with low cuboidal or flat epithelium, in a smaller number of cases, with cylindrical epithelium. In a certain group of animals (guinea pig, rat, mouse, opossum) there are typical cyclic changes. A fragile epithelium is replaced with a cornified, many-layered epithelium at the time of heat. This again is replaced by the fragile epithelium. In certain groups, after copulation, there is a formation of a membrane closing the vagina, which fixates the sperm. In all animals examined carefully, there is a distinct difference from the human in that the vaginae of the latter are full of bacteria. In these animals there is an entirely different mechanism which protects the genital canal from the passage of bacteria up the vagina. What, in the animal, prevents the bacteria from entering the vagina? Naturally—heat is a much shorter period in animals. The reaction in the vagina of the pig, lamb, guinea pig, and squirrel is alkaline. There is no formation of glycogen. In the vaginal wall small amounts of glucose are found. The vagina of squirrels, guinea pigs, etc., is self cleansing. In some animals (rat, and guinea pig) this is aided by leucocyte infiltration. In these animals, the vaginal mucosa is made up of squamous epithelium. In squirrels, which have cylindrical vaginal epithelium, after injection of germinal fluid into the vagina, one can not find an increase in agglutination. The alkaline vaginal secretion has no bactericidal action, the self cleansing action existing only so long as cylindrical epithelium is intact. In the normal vagina of a mature long tailed monkey, there is a slightly acid reaction, there are numerous vaginal bacilli, grape sugar is present in the same amount as in humans, and glycogen is found in the vaginal wall. It has been impossible to trace phylogenetic developments of the vagina in the animal kingdom, especially in primates.—*J. E. Lackner and S. S. Schochet.*

892. **BÜSING, KARL EDWARD. Die Theorien über das Geschlechtsverhältnis der Geborenen und die Geschlechtsbestimmung beim Menschen.** 64p. Ferdinand Enke: Stuttgart, 1928.—The author believes that statistics have afforded the ground structure for the problem of sex proportion for medical and biologic research. They showed the ratio of 105-106 boys to 100 girls to be normal in the countries studied, at the present time. The chromosome theory and the Siegel hypothesis are not sufficient for an explanation of the boy surplus. The author shows that constitution and hereditary predisposition have an influence. Probably young ova with female tendency are more likely to take up spermatozoa with a large number of chromosomes, and are prone to abort other spermatozoa. Germs with a male tendency may later change to female. As outer influences and constitution may effect the changes, the means of determining sex at will may yet be found. The boy: girl proportion in a population is an index of its strength and health. In-

crease in boys almost always signifies decrease of a nation's vigor, and points to disease, privation, or feebleness.—*B. Bickel.*

893. **CANTAROW, A., THADDEUS L. MONTGOMERY, and W. W. BOLTON. The calcium partition in pregnancy, parturition, and the toxaemias.** *Surg., Gynecol. & Obstetr.* 51(4): 469-475. 1930.—During the course of normal pregnancy (15 patients) and early labor (21 patients) there was a gradual diminution of total serum Ca, a slight increase in diffusible Ca, and a marked decrease in non-diffusible Ca. The ratio of diffusible to non-diffusible Ca increased steadily, reaching a maximum in the 1st stage of labor. In 7 toxemic patients the ratio of diffusible to non-diffusible Ca was subnormal, owing in most cases to an increase in the non-diffusible fraction. This suggests a condition of diminished cell permeability with associated disturbance of tissue functions in these disorders.

894. **CASTILLO, E. B. del, y C. CARDINI. Influencia de la insulina sobre la iniciación de los ciclos estruales en la rata blanca normal. [Insulin and onset of oestrual cycles.]** *Rev. Soc. Argentina Biol.* 6(4): 225-230. 1930.—Daily injection of 0.1 unit in rats (20-23 days old) did not modify time of opening of vagina, appearance of first oestrus and rhythm of cycle as compared with control litter mates.—*J. T. Lewis.*

895. **CASTILLO, E. B. del, y J. CALATRONI. Injerto de ovario en ratas enteras. [Ovarian graft in normal rats.]** *Rev. Soc. Argentina Biol.* 6(5/6): 341-350. 1930.—Intrarenal implantation of ovarian tissues gave 100% "takes" when the recipients were castrated females. In normal females only 41% "took" (7 out of 17); in these no corpora lutea were observed, and only in one case was a ripe follicle seen. Therefore when functioning ovaries exist in the organism it is less easy to graft a third ovary and this last shows signs of diminished activity in those cases in which the graft "takes."—*J. T. Lewis.*

896. **CERNOSVITOV, L. Studien über die Spermaresorption. I. Die Samenresorption bei den Oligochäten.** *Zool. Jahrb. Abt. Anat. u. Ontog. Tiere* 52(3): 487-538. 3 pl. 1930.—A resorption of normal spermatozoa takes place in 78 species belonging to 12 families of the order Oligochaeta (Naididae, Tubificidae, Enchytraeidae, Lumbriculidae, Branchiobdelidae, Lumbricidae, Criodrilidae, Glossoscolecidae, Microchaetidae, Megascolecidae, Acanthodrilidae, and Eudrilidae), from which it may be concluded that this phenomenon is wide-spread, though not invariably present in the order. Some spermatogonia and spermatocytes are destroyed in the early stages of development, by degeneration, decomposition, and phagocytosis. Commonly, complete normal spermatozoa are resorbed by means of ameboid cells (Spermatophages) in the seminal sac or in the body cavity. The spermatozoa may be destroyed either in the cytophore before maturation is complete or after separation from the cytophore. In some cases the spermatozoa are resorbed in the seminal vesicle through the epithelial cells. A part of the spermatozoa are resorbed in species which have a connection indicated between the seminal vesicle and the intestine. In no cases can the spermatozoa resorbed through the different cells and tissues be demonstrated to be pathological, and it can hardly be said that the phenomenon is a simple removal of impotent spermatozoa. In some cases free spermatozoa may degenerate and become absorbed by lymphocytes, or they may degenerate before separation from the cytophore in which case they become absorbed through the plasma.—*L. Černosvitov (transl. by F. W. Appel).*

897. **CHAMBERLAIN, E. NOBLE. Sex differences in the cholesterol content of tissues.** *Jour. Physiol.* 68(3): 259-264. 1929.—Suprarenal glands of non-pregnant ♀ rabbits were found to be much richer in cholesterol than those of ♂♂. During pregnancy this difference disappeared, perhaps because the excess was used up in forming new maternal and fetal tissues. The ovaries were also found very rich in cholesterol. Sex differences in liver, spleen, kidney and brain tissues, and differences between pregnant and non-pregnant ♀♀ in these tissues, were not great enough to be significant.—*P. Popenoe.*

898. **COPELAND, LYNN. Length of gestations in Jersey cows.** *Jour. Dairy Sci.* 13(3): 257-265. 1930.—The average gestation period for the 1075 cases studied was 278.51 days but there appears to be an equal chance of a cow calving any time between the 271st and the 285th day. The age of the dam apparently has no effect on the length of gestation. Bull calves were carried an average of one day longer than heifer calves, 297 bull calves being carried for an average of 279.48 days and the gestations of 282 heifer calves averaging 278.64 days. The data are too scant to draw conclusions relative to twin births but the results compare with those obtained by other investigators in that the gestations of twins are usually several days shorter than the average. Calves resulting from abnormally long gestations seem to have a better chance of living than do those born prematurely. No correlation could be detected between the length of different gestations in the same individual dam. Cows showing one or more short gestations also exhibited other gestations longer than the average and vice versa.—*Author's summary.*

899. **CORINALDESI, F. Asimmetria biochimica e funzionale degli ovari muliebri. [Biochemical and functional asymmetry of the human ovary.]** *Boll. Soc. Ital. Biol. Sperim.* 5(3): 347-352. 1 fig. 1930.—Physical and chemical asymmetry are shown to exist between right and left ovary. In the menopause the latter shows a more marked atrophy than the right; however, the involutive processes are alternately more intense in the one, then the other. In the resting as in the functional stage metabolic activities are more marked in the right ovary: so is it with the increase in weight and the increase of cholesterol content during activity.—*M. Camel.*

900. **CORNER, GEORGE, W. The hormonal control of lactation. I. Non-effect of the corpus luteum. II. Positive action of extracts of the hypophysis.** *Amer. Jour. Physiol.* 95(1): 43-55. 1930.—The administration to non-pregnant spayed rabbits of corpus luteum extract (progestin) did not cause proliferation of the mammary gland beyond the stage normally attained at puberty. The continuous presence of corpora lutea in the ovaries, during a period equal to that of normal gestation (brought about by experimental means), was equally ineffective in altering the mammary gland. Administration of extracts of whole sheep's hypophysis to spayed virgin rabbits caused proliferation of the mammary gland and simultaneous lactation, producing in 2 weeks a condition scarcely distinguishable from that present at the full term of gestation. Previous preparation by action of the corpus luteum was found not to be necessary to this effect.—*Author's summary.*

901. **CUNNINGHAM, J. T. The influence of lactation on ovulation and oestrus.** *Brit. Med. Jour.* 2(3638): 516-517. 1930.—According to Crew and Mirskaia oestrus and ovulation occur in the mouse within 24 hrs. of parturition, and if no fertilization then takes place there is no second oestrus for an interval of 20 to 25 days, which is the normal duration of lactation. The theoretical explanation proposed is that the stimulus of sucking acts on the anterior lobe of the pituitary, and that the excess of pituitary secretion so produced causes the persistence of the corpora lutea. There is no general correlation between the stimulus of sucking and the suppression of oestrus, as is assumed by the theory of Crew and Mirskaia. This correlation occurs in the mouse and rat, in the ferret, the rabbit, and the Virginian opossum, but it is absent in cow, mare, goat, pig, and frequently, if not always, in the human species. Cunningham believes that the really significant correlation is between the suppression of oestrus and the condition of the newborn young. In those cases where oestrus is inhibited the young are naked, immature and kept for the greater part of the time enclosed in a warm nest in close contact with the mother. In the other cases where oestrus occurs during lactation, as in the cow and the guinea-pig, the young are born covered with hair and able to

run almost at once. This argument is developed at length.

902. **DIERKS, K. Experimentelle Untersuchungen an menschlicher Vaginalschleimhaut.** *Arch. Gynäkol.* 138 (1): 111-130. 9 fig. 1929.—A young ovariectomized girl was given a sufficient quantity of ovarian active substance to produce premenstrual changes in the genital tract. Following the administration of the hormone there was an increase in the thickness of the vaginal mucosa. The increase was not the result of a simple hypertrophy but a hyperplasia of the cells in the basal layer of the epithelium where mitotic cells were seen in the premenstrum. The vaginal epithelium was divided into 3 layers each containing a different type of cell. The author pointed out similar findings in the microphotographs of sections of the vaginas of animals under similar experimental conditions reported by other investigators. All of these sections showed a basal, an intra-epithelial and a cornified layer. The basal layer remained approximately the same thickness throughout the cycle. The intra-epithelial layer of cornification was not clearly seen until after the 4th day following menstruation. The thickness of this layer increased very slowly and it never became more than ¼ the thickness of the basalis. The exact number of cells in each layer was not determined. The cornified layer began to increase in thickness immediately after menstruation and rapidly became many cells thick in the premenstrum. Cyclic changes were noted in the tubes and uterus as well as in the vagina.—*D. D. Baker.*

903. **DUNCAN, F. N. Some observations on the biology of the male Drosophila melanogaster.** *Amer. Naturalist* 64(695): 545-551. 1930.—A vigorous male *Drosophila melanogaster* should produce from 10,000 to 14,000 offspring; a smaller, less vigorous male should produce about 7,500. The average fertile period of males is about 32 days. Following the fertile period is a sterile period which varied in time in the males used from 21 to 34 days. Sperm were observed in the testes of all males after their fertile period was over. Mitotic figures were found in sections of the testes of males after they had come to the period of sterility, showing that sperm were still being formed. Tests were made to find out whether the failure of sperm from old males might not be due to a deficiency of some fluid from the accessory glands. The results indicated that this was not the case. No sperm were found in the sperm receptacles of females that had mated to these males during their sterile period, excepting, of course, the cases of double matings. Therefore, the impotency of the old males must be due to a loss of function in the ejaculatory apparatus.—*Author's summary.*

904. **EICHBAUM, FRANZ. Das Verhalten des arteriellen Blutdruckes im menstruellen Zyklus und seine Abhängigkeit vom vegetativ-hormonalen System. 1. Mitteilung.** *Arch. Gynäkol.* 138(1): 168-173. 1929.—Eichbaum divides his work into two parts: 1. Early changes in blood pressure during menses, paying attention to diastolic blood pressure and pulse amplitude. 2. Dependence of blood pressure on stimulation from vegetative nervous system during the menstrual cycle. (Especially in regard to changes in irritability due to adrenalin.) Examination made 2-3½ hrs. after noon. The author calls those cases positive in which the premenstrual and menstrual blood pressure varies. Negative, those cases in which there are no characteristic changes to be connected with the menstrual cycle. Of 50 cases, 24 were positive and 26 were negative. Most of the positive cases had a premenstrual rise and menstrual fall. Occasionally one gets a menstrual increase in blood pressure. A negative result occurred in 52% of the cases due to hypotonia.—*S. S. Schochet and J. E. Lackner.*

905. **EICHBAUM, FRANZ. Das Verhalten des arteriellen Blutdruckes im menstruellen Zyklus und seine Abhängigkeit vom vegetativ-hormonalen System. II.** *Arch. Gynäkol.* 138(1): 174-186. 4 fig. 1929.—The author attempts to determine whether, during the menstrual cycle, one gets changes of sensitivity to epinephrine as an expression of changes in the vegetative nervous system. During the menstrual state there is a decreased sensitivity to epinephrine. This may be due to ovarial hormonal action with its changes in extra genital organs. The conclusion is that there is no typical picture which shows an increased sympathetic or vagus tone. One can draw no conclusions from these experiments on antagonistic action in the vegetative nervous system. The changes of the epinephrine curve during the extra menstrual phase do not seem to be related to the cyclical ovarial changes. During menstruation there is a decreased irritability to adrenalin; this is a reaction against substances increasing blood pressure and seems to correlate with the decrease in blood pressure during menstruation. Neither changes in blood pressure nor the periodic changes in irritability to adrenalin are characteristic of all mature women.—*S. S. Schochet and J. E. Lackner.*

906. **EMERY, FREDERICK E. Changes in the ovary and oestrus cycle following the removal of one ovary in albino rats.** *Physiol. Zool.* 4(1): 101-110. 1931.—A large number of albino rats have been studied in respect to the oestrous cycle before and after semiovariectomy. In the normal control rats the cornified-cell stage of oestrus averages about 36% of the total oestrous cycle; this compares to a cornified-cell stage of 40 to 60% of the total cycle characteristic of unilaterally ovariectomized rats. The normal rat is rarely in continuous oestrus for more than 5 days, while rats with but one ovary not infrequently remain in heat for 10 or more days in succession. Ovarian cysts were more often present in the surviving ovaries than in ovaries of normal rats. The relationship of these changes to the gonad-stimulating hormone of the anterior pituitary is pointed out.—*Author (courtesy Wistar Bibl. Serv.).*

907. **EUFINGER, HEINRICH. Die Xanthoproteinreaktion im enteiweissten Blut während der Gestationsperiode.** *Arch. Gynäkol.* 143(2): 366-375. 1930.—The xanthoproteic reaction was positive (values higher than 28, highest obtained in 30 normal women in intermenstrual period), twice in 80 pregnant subjects, once in 40 parturient, and 77 times in 175 puerperal; higher during puerperium in 15 subjects in whom 2 tests were made; positive in 5 of 15 subjects with nephropathy, in 5 of 10 with eclampsia, in 6 of 13 with unirradiated carcinoma, and strongly so in 9 of 12 with carcinoma irradiated 1-2 mo. previously. Fractionation of the total xanthoprotein figures makes it seem probable that an increase of the intermediary, aromatic amino acids is to be considered as an expression of the autolytic processes in the uterus during the puerperium.

908. **EVANS, HERBERT M., and OLIVE SWEZY. The uterus ovary relationship and its bearing on the time of ovulation in primates.** *Amer. Jour. Physiol.* 96(3): 628-639. 1931.—A critical review of available evidence indicates that none of the 4 different lines of approach to this subject, the condition of the ovary, the condition of the uterus, the length of pregnancy, or the time of conception, justifies us in assigning ovulation to an invariable period of the menstrual cycle even though the period be broadly defined. In particular the conception of the uterus-ovary relationship given herewith enables one to utilize differently Schroeder's careful histological study of hundreds of endometrial scrapings, and to conclude that ovulation, while more apt to occur in the mid intermenstrum, occurs at all times in the human menstrual cycle.

909. **FEE, A. R., and A. S. PARKES. Studies on ovulation. III. Effect of vaginal anaesthesia on ovulation in the rabbit.** *Jour. Physiol.* 70(4): 385-388. 1930.—Of 8 ♀ rabbits copulating during anesthesia of the vagina and vulva, 7 ovulated in the normal manner. The animals were opened under urethane at 12 hrs. after coitus, and the occurrence or otherwise of ovulation determined by the ordinary ovarian signs. Where ovulation had not taken place at 10 to 12 hrs., observations were made for a further period before killing the animal. It was found that local anesthesia of the vagina and vulva in the rab-

bit does not affect either the copulatory reflex or the occurrence of ovulation after copulation.

910. **FRETWURST, F., und K. OTTO. Die Manoiloffsche Schwangerschaftsreaktion.** *Arch. Gynäkol.* 143(2): 459-464. 1930.—Manoiloff's reaction (M.R.) was positive in 49 of 130 pregnancies, once in 41 subjects in the first 3 mos., 40 times in 66 subjects between the 8th and 10th mo. In 58 healthy, nonpregnant women and 64 healthy men the reaction was negative. In 36 patients with diseases which frequently give a positive reaction in other pregnancy reactions, only 3 reactions were positive, 2 in cardiac insufficiency, 1 in renal atrophy. In 24 cases the reaction was repeated with the same result. The reaction is undoubtedly not due to the alkalescence of the serum nor to the presence of sexual hormones and the authors' assumption that there might be a shift of the protein components to the grossly disperse side could not be proved unequivocally. The reaction apparently is dependent upon the concomitant presence of serum colloids and other, unknown factors.

911. **GARDNER, J. ADDYMAN, and HUGH GAINSBOROUGH. The cholesterol metabolism during pregnancy.** *Lancet* 1(5508): 603-606. 1929.—The authors examined a number of women attending the antenatal clinic at St. George's Hospital who were admitted to the lying-in ward for parturition. Blood specimens were taken at monthly intervals before parturition and once or twice during the period of confinement. The following results were obtained: (1) The free cholesterol of the plasma increases during pregnancy up to a maximum at about the 30th wk.; concurrently the ester cholesterol falls to a minimum at about the same time. (2) From the 30th wk., more or less approximately, the amount of free cholesterol decreases and the ester cholesterol increases till an almost normal ratio of free to ester cholesterol is attained near parturition. (3) The plasma cholesterol values are generally normal in the 1st wk. or 2 of the puerperium. (4) Some cases show a definite total hypercholesterolemia in which the total cholesterol figures run roughly parallel to the free cholesterol values. During pregnancy there is a marked disturbance of the cholesterol metabolism which results in large changes in the ratio of free to ester cholesterol in the plasma, but to less definite changes in the total cholesterol.

912. **GOLDHAMMER, HELENE. Über den Cholesteringehalt normaler und eklamptischer Placenten. [The cholesterol content of normal and eclamptic placentas.]** *Biochem. Zeitschr.* 226(4/6): 401-403. 1930.—The cholesterol content of 10 normal placentas averaged 0.91%, and 10 eclamptic placentas, 0.65% of the dry weight.

913. **HANKINS, FRANK H. Does advancing civilization involve a decline in natural fertility?** *Publ. Amer. Sociol. Soc.* 24(2): 115-122. 1930.—It is important to discover whether any, and if so how much, decline in the birth rate is due to natural causes affecting the fecundity of the population. A significant decline in natural fertility might indicate the onset of genuine racial decay. There are evidences of reduced natural fertility in the increased percentage of sterile unions and of small though unlimited families among the intellectual classes. This lower fertility of the upper classes, as also of urban populations, is explained primarily by the more general use of contraceptives. But it seems to be due in part to reduced reproductive vigor, which in turn may be due to wider dissipation of nervous energies. It would seem that the increasing strains of complex social life, accompanied by the increased necessity of egoistic satisfactions, must reduce the energies available for reproduction. In that case, reduced natural fertility would be in harmony with Herbert Spencer's principle of the opposition of individuation and genesis. The whole subject urgently needs investigation.—*F. H. Hankins.*

914. **HARGITT, GEORGE T. The formation of the sex glands and germ cells of mammals. V. Germ cells in the ovaries of adult, pregnant, and senile albino rats.** *Jour. Morph. & Physiol.* 50(2): 453-473. 2 pl. 1930.—Ovaries of adult albino rats were studied, the following phases being considered: Eleven to 20½ days pregnant, shortly after fertilization, oestrus, not pregnant, young sterile, old, and senile. Some new ova are produced from the germinal epithelium during pregnancy and oestrus, but it is in the ovaries of non-pregnant animals between oestrous periods that the germinal epithelium is most active. There can be no question of the formation of new ova during adult life, for there is a correlation between the activity of the germinal epithelium and the number of oocytes and young follicles present in ovaries. Also one can trace the origin of ova in the surface and follow their transformation and movement into the ovary proper. In some sterile young animals little new formation took place, in others a good deal. In old and senile animals the germinal epithelium continued to be active, especially in producing ingrowing cords of cells, but frequently these were anovular. The germinal epithelium may form different types of cells by ingrowth: ova, follicle cells, and interstitial cells, but the formation of anovular follicles at one period does not prevent a later production of normal ova and follicles. —*Author (courtesy Wistar Bibl. Serv.).*

915. **HASELHORST, G., und K. STROMBERGER. Über den Gasgehalt des Nabelschnurblutes vor und nach der Geburt des Kindes und über den Gasaustausch in der Plazenta. I.** *Zeitschr. Geburtsh. u. Gynäkol.* 98(1): 49-78. 2 fig. 1930.—During the last weeks of pregnancy the O-content of the umbilical-arterial blood is 0.84 vol. % (average of 5 determinations), in the umbilical vein it was 3.97 vol. %. The Co_2-content was 47.03 vol. % and 44.95 vol. %. Immediately after birth, but before respiration the O-content of the arterial blood was 3.40% (23 determinations), in the vein it was 10.14% (22 determinations). The CO_2-content was 46.21% and 40.71%. During parturition the values vary between wide limits. The elevation of the O value during parturition is probably due to the activity of the labor pains and the consequent change in the circulatory relationships which shows up on the maternal as well as on the fetal side. The total O capacity of the fetal blood at the time of parturition was found to be 21.92% (30 determinations). The high value is due to the high hemoglobin content of the fetal blood. The manner of gas interchange in the placenta suggests a dissociation curve.—*Authors' summary (transl. by. C. S. Simkins).*

916. **HASELHORST, G., und A. ALLMELING. Die Gewichtszunahme von Neugeborenen infolge postnataler Transfusion.** *Zeitschr. Geburtsh. u. Gynäkol.* 98(1): 103-104. 1930.—In 120 cases the average increase in weight in the new-born from influx of blood through the uncut umbilical cord was 50.4 gm. in the 1st min. and 97.7 gm. by the 30th min.; or, taking the amount of increase up to and including the 30th minute as 100%, that in the 1st minute was 51%, in the 1st 5 minutes, 79%, in the 1st 10 minutes, 91%, in the 1st 20 minutes, 99%.

917. **HILGENBERG, FRIEDRICH C. Über Beziehungen des Eisengehaltes der menschlichen Plazenta zur Fruchtentwicklung.** *Zeitschr. Geburtsh. u. Gynäkol.* 98(2): 291-299. 1930.—The Fe content of 35 placentae per 100 gms. fresh substance (without reference to the duration of pregnancy) averaged 2.4 mgm.; 14 placentae from male births averaged 2.3 mgm.; 21 from females 2.48 mgm. The average when fetus weighed 530-1500 gms. was 1.97 mgm., in premature cases with infants weighing from 1550-2700 gms., 2.50 mgm., in normal infants of 2800-3500 gms., 2.63 mgm., and in over-due infants of 3550-4800 gms. it was 2.38 mgm. Taking average Fe content of 2.63 mgm. per 100 gm., in placentae of infants of 2800-3500 gm. as normal, then the content in other groups is 25.1, 4.94, and 12.2% less than normal. The Fe content of the placenta increases directly with the progress of pregnancy to full development, then falls.—*W. P. Kennedy.*

918. **JOYET-LAVERGNE, PH. Métabolisme et Sexualité.** *Protoplasma* 7: 448-463. 1 fig. 1929.—The numerous measures used to evaluate basal metabolism in man have shown that there exists a difference in the basal metabolism in relation to sex. The metabolism of the male was, on an average, 6-7% higher than that of the female. This characteristic of sex cannot be traced directly to a

difference in the function of the genital glands or of the hormones of one or the other sex and we cannot consider it as a kind of secondary sexual character. The researches of Riddle and his collaborators upon the metabolism of the pigeon have shown that, for the egg and embryo of that species, the metabolism of the male is higher than that of the female. Several other studies show the same difference of metabolism in favor of the male of other genera: the rat, batrachians, etc. This characteristic of sex is a result of higher respiratory activity in the cells of that sex. The interpretation of the results of Riddle upon embryos permit us to explain the higher respiratory activity of these cells on their more elevated power of oxidation (intracellular rH). The sexual differences in metabolism appear as a manifestation of the first law of cytoplasmic sexualization ("In a species, the cells polarized in the female sense have an inferior rH to those of the cells polarized in the male sense.") and one can suppose that these metabolic differences have as great a generality as the law of which they are one of the consequences.—*L. Moyer.*

919. JOYET-LAVERGNE, PH. L'avitominose B et la sexualisation cytoplasmique. *Protoplasma* 8: 443-466. 1929.—The article is a review of the subject treated especially from the viewpoint that sexualization of the cytoplasm is influenced by such factors as oxidation-reduction potential and the nature and proportion of reserve lipids and fats.—*W. Seifriz.*

920. JOYET-LAVERGNE, PH. L'intersexualité et la sexualisation cytoplasmique. *Rev. Gén. Sci. Pures et Appl.* 41(19): 533-543. 1930.—In animals and plants intersexuality may be produced by the following: Racial crossing, tumors, intoxication, parasitic action, change of surrounding temperature. These factors act by disturbing the metabolism in the organism. In the majority of cases examined the sexual changes effected may be regarded as results of the two laws of cytoplasmic sexualization. The idea of sexual polarization is applicable not only to the germ cells but also to the somatic cells.—*P. Joyet-Lavergne.*

921. JUST, E. E. Initiation of development in Arbacia. IV. Some cortical reactions as criteria for optimum fertilization capacity and their significance for the physiology of development. *Protoplasma* 5: 97-126. 1928-1929.—Eggs of optimum fertilization capacity exhibit high fertilizin content and separate membranes uniformly and rapidly after insemination. Uninseminated, such eggs separate membranes in 5 sec. in tap or distilled water; they form extra-ovates in 30 sec. when exposed to tap or distilled water 3 min. after insemination. All these reactions are associated with the best physiological condition of the egg. Under proper conditions, eggs without jelly fertilize, separating normal membranes. They develop as well as eggs with jelly. The speed of the fertilization-reaction is so great that polyspermy cannot be induced in eggs in optimum condition by an excess of sperm. Nevertheless, the fertilization-reaction may be chemical in nature. These results serve to emphasize anew the leading rôle played by the cortex in the fertilization-reaction. The cortex of the egg is significant in other ways for the physiology of development.—*Author's summary.*

922. KESSLER, ROB. Glykogengehalt von Plazenta und fötaler Leber bei künstlicher Hyperglykämie. Beitrag zur Frage der Glykoregulation zwischen Mutter und Föt. II. *Zeitschr. Geburtsh. u. Gynäkol.* 98(3): 487-495. 1930.—Twenty-three placentas and 17 livers were examined, 10 placentas being from the 3rd to the 8th mos. of pregnancy. A 2nd group of 8 term placentas from normal pregnancy gave an average value of 0.062 gm. %, the lowest content doubtless being at the end of pregnancy. A 3rd group of 8 were from mothers in whom hyperglycemia had been produced by oral or intravenous administration of glucose. It was concluded that: (1) The term placenta has a constant glycogen content of about 0.1 gm. % which is not influenced by alimentary hyperglycemia. (2) The liver of a mature or nearly mature fetus with normal organs contains glycogen up to 3.4 gm. %. (3) In confirmation of earlier observations, glycogen decreases in the placenta during fetal development but shows an increase in the liver. The beginning of this function is in the 4th mo. of pregnancy, the fetal liver from that time assuming control of the fetal carbohydrates in complete independence of the mother.—*Transl. by R. S. Siddall.*

Gynäkol.* 84(4): 275-280. 1930.—Under carefully controlled conditions breasts of lactating women were exposed to sunlight, or radiant lamp rays. The skin became deeply pigmented. Neither total amount nor rapidity of secretion was raised.

924. LeBLANC, T. J. Some aspects of paternity in Sendai, Japan. *Human Biol.* 2(4): 508-522. 1930.—An analysis is presented of births in Sendai, Japan, for 1920 by occupation and age of father. Using population statistics on occupation and age, rates are presented which indicate how much each age group in the various occupational groups, is contributing to the increase in total population. Using all ages, the rates array themselves in descending order as follows: miscellaneous, commercial, officials and professions, agriculture, unoccupied, industrial and communications. If the rate is made specific for age and only includes those fathers of 45 years of age or over, on the assumption that such fathers represent individuals of more than the average fertility, the rates array themselves as follows: miscellaneous, officials and professions, communications, commercial, industry, agriculture and unoccupied. These rates suggest that so-called differential fertility is operating, but the author is unable to advance any evidence indicating whether such a state of affairs is desirable or not.—*T. J. LeBlanc.*

925. LIPSCHÜTZ, A. Die experimentellen Grundlagen der Eierstocksverpflanzung. (Abh. Grenzgeb. inn. Sekretion, Heft 6.) 51p. 9 fig. Rud. Novak & Co.: Budapest & Leipzig, 1930. Pr. 3 M.—This book is essentially a summary, for the clinician, of the knowledge about ovarian transplantation in experimental animals, and to the underlying principles. Auto-, homo- and heterotransplantation are discussed. The first has the greatest chances of success and the last the least. The work of Voronoff and Thorek in the human has not been sufficiently controlled. Temporary effects of transplanted glands may be due to products of autolysis. The gland must take root in order to have a lasting effect as an endocrine organ. Many interesting facts related to the dynamics of the transplantation of the ovary are given and the most recent work of well known investigators in this field is noted. Especially interesting is the account of transplantation of "conserved" ovaries, some of which took successfully even after 16 hrs. out of the body. The author's work with partly desiccated ovaries is mentioned in this connection. The clinician is constantly warned not to expect too much in this kind of work and one gets the impression that the author is very doubtful that any real good can result from homotransplantation in the human. The photographs and microphotographs are very good.—*G. L. Kelly.*

926. MANDRUZZATO, PRIAMO. Sulla genesi della dilatazione degli ureteri in gravidanza. [The cause of dilatation of the ureters in pregnancy.] *Clin. Ostetrica* 32 (10): 601-605. 1 fig. 1930.—A radiogram of the ureters injected with Uroselectan in a woman in the 6th mo. of pregnancy and necropsy on a woman dead at term agree in showing the upper ⅔ of the ureters dilated, the lower ⅓ of normal caliber. The author attributes the dilatation to atony and an obstacle at the level of the innominate line.

927. MARCO, ROCCO DE. Sul significato del liquido fluente dall'utero di cagna nel periodo di calore. [On the meaning of the liquor flowing from the uterus of dogs during rut.] *Arch. Fisiol.* 29(2): 181-190. 4 fig. 1930.—By means of uterine fistulae the liquor flowing from uterus of dogs during rut was obtained; its secretion is increased by pilocarpin administration, whereas in most cases atropin and pituitrin caused it to decrease,

and aloes increased it. The action of eserin was uncertain, and that of saccharose negative. The mechanism of production of the liquor is a secretive one.—*M. Comel.*

928. **MATTICK, E. C. V., and H. S. HALLETT. Studies in lactation. I. Variations in some chemical and physical properties of the milk from individual quarters of a cow.** *Jour. Dairy Res.* 1(1): 37-49. 1929.—A 4-year old cow was fed an almost uniform ration for a whole lactation. The milk from each quarter was extracted separately using aseptic methods. In the first 2 mos. the yield from the 2 hind quarters was double that of the front, but the former decreased more rapidly until both were the same. Titratable acidity decreased in all quarters as lactation advanced, particularly in the rear. The time for rennet coagulation followed inversely; pH increased, the quarters varying independently. Total N and casein N varied at first; later there were no significant differences. Solids other than fat and ash showed slight irregular differences. Butterfat percentage varied inversely as the yield. On the whole the milk from fore quarters was similar, and also that from hind quarters, but there were distinct differences between fore and hind. Occasionally striking peculiarities marked the milk of single quarters. A physiological explanation is needed.—*S. A. Asdell.*

929. **MEYER, ROBERT. Über Funktion des Ovariums insbesondere des Corpus luteum.** *Ber. Ges. Gynäkol. u. Geburtsh.* 13(5): 241-273. 1928.—The persistence of the corpus luteum during pregnancy is of functional significance. Meyer says there is no function of the corpus luteum without ripening of the ovum; no function of the mucosa without corpus luteum. There are many differences of opinion concerning quantity, quality, source, and function of the lipids in the corpus luteum. Fat is present in the smallest quantities and smallest drops when the cells are developing and large, so that one can differentiate between early developing theca and later developing granulosa. The thick lipid drops are present in the corpus luteum of menstruation and in the corpus luteum after pregnancy, or following interruption of pregnancy. One is unable to determine chemically the nature of fats in the tissues. The increase in visible fat at menstruation coincides with histological regeneration through decomposition of cells. The lipid is freed and only then becomes visible. The fat in combination with other substances in the cells functionates in the pregravid and gravid state. Chemical analysis tells us little of the function of the fats. The corpus luteum prevents further ovulation and during pregnancy, for this reason, prevents superfetation. The hormone (folliculin) of humans and of animals causes growth of the uterus and heat. Hartman and Loewe believe that these two changes are caused by two distinct substances. However, growth of uterus may be caused by other substances such as aolan. The hormone causing heat is found in the ovary, corpus luteum, follicle, liquor folliculi, placenta, blood serum, in the menstrual blood; in puerperal women two days post partum, in blood, in placental blood, liquor amnii, in the urine of pregnant women from the 4th month to the first few days post partum. These are merely the sites of the accumulation of the hormone and not its source. Ovarian function is dependent on other organs, influenced by the vitamin intake, by infections, and poisons. The hormone of the anterior portion of the hypophysis is the motor of the sexual function and stimulates the follicular apparatus causing ripening of the follicle, and is trophic but not rhythmic. The ovum controls the rhythm. The hormone of the anterior portion of the hypophysis of both sexes has the identical action in the ovaries. It is the primary hormone and the ovarian hormone is the secondary hormone. In both sexes of the rat, after castration, there are marked changes in the cells of the hypophysis. These changes can be eliminated in the male by hormone from the testicle only, and in the female by the hormone from the ovary only. The action of the hormone of the testicle and ovary on the hypophysis is different and is specific for the sexes. One must warn against the suggestive influence on the patient of ovarian transplantation and hormone injection. Frank and Goldberg hope (however, R. Meyer says this is premature) that by determining the presence of the hormone in the blood, one can determine the time of ovulation, differentiate between the hypo- and hyperhormone action in meno- and metrorrhagias, and determine the sex in questionable cases by the action of the ovarian or the testicular hormone. The hormone is of great value in diagnosing pregnancy. It is of therapeutic value because it improves metabolic processes and sex function. Ovaries that functionate can be stimulated by the hormone. If the cause of sterility lies in the uterus, Zondek hopes to stimulate the endometrium and through it increase the chances for nidation of the ovum. Only the combining of all methods of research will enable us to draw conclusions as to the function of hormones. It is wrong to demand more from the biologists than has been accomplished. One must wait for further research to determine which results can be applied clinically and of what value they are.—*S. S. Schochet and J. E. Lackner.*

930. **MOORE, CARL R. Supplementary observations on mammalian testis activity. I. Vasa-efferentia ligation. II. Atypical scrota.** *Anat. Rec.* 48(1): 105-119. 1 pl., 1 fig. 1931.—An account of ligation of vasa efferentia in the guinea-pig, with examination of testes 6 mos. later, and report of congenital absence of epididymis in adult guinea-pig. In both conditions testes continue normal spermatogenetic activity with production of spermatozoa. This refutes recent contentions of others that closure of vasa efferentia effectively prevents further spermatogenesis. Tubules may undergo temporary involution from pressure atrophy, but upon removal of degenerating masses of spermatozoa through resorption the germinal epithelium is rebuilt and spermatozoa are produced. More than 50% of the seminiferous tubules of an adult guinea-pig with congenital epididymal absence were normal and contained spermatozoa. Two cases of atypical placement of the scrotum to a ventral median position in the abdomen of the rat are described. The testes, though in the saccus vaginalis as in the normal, were not surrounded by the hairless thin skin of the scrotum nor removed from the influences of body temperature, hence full heat-regulatory function of the scrotum was not possible. The testes, though spermatogenetically active, produced spermatozoa in but one small peripheral area 2 tubules in thickness, which is presumably the portion applied against the skin. A subnormal scrotal function was accompanied by subnormal testicular activity. —*Author (courtesy Wistar Bibl. Serv.).*

931. **MORACCI, E. Poliglobulia e leucocitosi asfittica in diverse fasi delle funzioni sessuali. [Asphyxial polyglobulia and leucocytosis during different stages of sexual functions.]** *Boll. Soc. Ital. Biol. Sperim.* 5(5): 707-711. 1930.—Asphyxial polyglobulia is more marked during sexual rest than during rut. Asphyxial leucocytosis is present only during sexual rest (in dogs).—*M. Comel.*

932. **MORELLI-GUALTIEROTTI, MARIO. Contenuto cellulare del latte umano e sua importanza per lo sviluppo del lattante. [Cellular content of human milk and its importance for the infant's development.]** *Riv. Clin. Pediatr.* 28(7): 574-582. 1930.—The cellular content of the human milk fed to 40 infants consisted of the epithelial cells of the mammary gland and of leukocytes and lymphocytes (which seemed to have conserved their vitality) and of detritus of various kinds and volume. In normal milk the av. number of these elements per cu. mm. was about 5500. The author observed a constant relation between the number of these elements and the growth of the infant fed on the milk, indicating a favorable effect on growth.

933. **MRŠIC, WILHELM. Über die Eireifung bei der Forelle und deren Bedeutung für die übliche Methode der künstlichen Laichgewinnung.** *Arch. Hydrobiol.* 21(4): 649-678. 1930.—Eggs of a rainbow trout, after stripping, were divided into 4 portions, the most posterior (tail) being the 1st, and the most anterior (head), the 4th, in order to determine whether there might be any differ-

ence in ripening, and hence fertility, development, etc. Each of the 4 portions was fertilized with milt from 4 separate males. All of the portions were placed under identical conditions. No differences were noted in the fertility, mortality, weakness or tendency to abnormalities, or in any other respect. The number of "day-degrees" was 1200-1230 to the commencement of hatching, and 1450 to the end.—*From abst. by W. Mršic (transl. by R. H. M'Gonigle).*

934. **NAKAYAMA, S. Autolysis of gastric mucosa of rabbit in pregnancy and puerperium.** *Japanese Jour. Obstetr. and Gynecol.* 13(2): 171-175. 1930.—Experiments in vitro indicated that autolysis of the gastric mucosa in the rabbit is caused perhaps by "cathepsin" or by an autolytic ferment, but not by pepsin, and is most active at pH 2.27-3.94. The autolysis of the white and the red parts of the gastric mucosa was studied in 10 normal non-gravid rabbits, 11 pregnant rabbits, and 10 rabbits in puerperium. Autolysis was more active in the heavier animals, and in the red than in the white portion of the gastric mucosa. Contrary to Laufberger, Nakayama found that activation of autolysis of the gastric mucosa (unlike that of the liver and kidneys) was insignificant in pregnancy. Autolysis of the gastric mucosa, however, was much increased in the puerperium, paralleling the clinical observation that gastric ulcer is aggravated in puerperium.

935. **NISHIZAKI, Sh. Tubal sterilization through uterine cavity. Report 1. Experimental study of electrocoagulation with rabbits.** *Japanese Jour. Obstetr. & Gynecol.* 12(4): 280-284. 1929.—The previous attempts at visual observation of the uterine cavity with an endoscope are briefly reviewed. It is possible to see the uterine mucous membrane as well as the tubal orifice in the uterine cavity in vivo by passing the instrument through the vagina and cervix. By destroying the tubal mucous membrane and muscle at the orifices in the uterus as well as a portion of the interstitial end of the tubes by electrocoagulation, bloodless tubal sterilization becomes possible. The author devised a cystoscope as well as a diathermy apparatus for this purpose. Experimentally on laparotomized rabbits, he passed his electrocoagulating apparatus through an incision in the vaginal ends of the uterine horns, and with a given length of spark for a period of 5 to 7 sec. electrocoagulated the tubo-uterine orifices. Subsequent histological examinations showed the destruction of the tubal mucous membrane as well as muscle and their replacement by scar tissue. Communication between the uterine horns and the uterine cavity is thus destroyed.—*R. Kurzrok.*

936. **NISHIZAKI, Sh. Tubal sterilization through the uterine cavity. Report 2. Morphometric research on the uterine cavity and the course of the intramural segment of the fallopian tube: electrocauterization with the author's instruments on the intramural segment of the fallopian tube of the extirpated uterus and its effect.** *Japanese Jour. Obstetr. & Gynecol.* 12(4): 285-295. 2 pl. 1929.—To carry out tubal sterilization in the human in vivo the author experimented on human extirpated uteri and determined the size, shape and volume of the uterine cavity, as well as the course and length of the intramural segment of the fallopian tube. The course of the latter is upwards, backwards, and outwards. He then performed bloodless tubal sterilization by cicatricial occlusion of the living uterus in situ.—*R. Kurzrok.*

937. **NISHIZAKI, Sh. Skin pigmentation during pregnancy. Experimental study on the way of pigmentation in the skin of pregnant women and the pigmentation degree in toxemia of pregnancy.** *Japanese Jour. Obstetr. & Gynecol.* 12(4): 377-386. 1929.—At the Kyoto university a series of examinations on pregnant women with various types of toxemia were made to determine the degree of cutaneous pigmentation. It was concluded that melanin in pregnancy is due to increased chromatogenous substances in the blood at a time when the tonus of the sympathetic nervous system is markedly increased. There is an acceleration of pigment precipitation. The degree of pigmentation, in a manner, indicates whether an individual is well adapted to pregnancy or not.—*B. Bickel.*

938. **PADOA, EMANUELE. Il piumaggio e gli ornamenti della testa di galline imperfettamente ovariectomizzate. [Plumage and head appendages of hens following imperfect ovariectomy.]** *Boll. Soc. Ital. Biol. Sperim.* 5(4): 590-593. 1930.—In 3 ovariectomised hens after regeneration of the ovary rests a scission between plumage and comb characters was observed, the former being feminine, the latter becoming a capon comb.—*M. Comel.*

939. **PASCALI, SILVIO. La riserva alcalina nel sangue durante la gestazione. [Blood alkaline reserve during pregnancy.]** *Clin. Ostetrica* 32(9): 537-554. 1930.—Study of 45 cases during all stages of gestation shows that during the first 3 mos. there is a regular and evident though not extreme depression of the alkaline reserve (A. R.) of the blood; that from the 4th to the 8th mos. the A. R. is within normal limits; and that in the 9th mo. the A. R. is almost normal until the onset of labor, when it tends to fall. Pascali attributes the fall during the 1st 3 mos. to the unpreparedness of the organism for the new conditions, necessitating a certain time for the various organs to adapt themselves to the work demanded of them.—*Author's summary (transl.).*

940. **PETERSEN, W. E., L. S. PALMER, and C. H. ECKLES. The synthesis and secretion of milk fat. I. The time of milk and fat secretion.** *Amer. Jour. Physiol.* 90(3): 573-581. 1929.—Six cows were used in studying the time of milk and fat secretion. Comparisons are made of the post-mortem milking with the in-vivo milkings for amounts of milk and fat percentage for all 6 cows and for sugar, ash, and total solids for 2 cows. As either more or nearly as much milk was secured in the post-mortem milkings as in the in-vivo milkings it is concluded that the cow's udder not only can but does contain practically all the milk produced at a milking. The much lower fat content of the post-mortem milking lends support to a hypothesis that milk fat is secreted by a separate mechanism from the one responsible for the secretion of the other ingredients of milk.—*A. H. Frank.*

941. **PETERSEN, W. E., L. S. PALMER, and C. H. ECKLES. The synthesis and secretion of milk fat. II. An analytical study of the fat of the bovine mammary gland.** *Amer. Jour. Physiol.* 90(3): 582-591. 1929.—Glands were studied from cows at various stages of lactation and during the dry period. The dry glands were found to contain much less dry matter and fat than those in milk, indicating a marked atrophy of the gland as lactation ceases. Fat was found to be one of the chief constituents in the lactating gland, comprising on the average 40% of the dry matter. The nature of the fat from lactating glands differs widely from that of the non-lactating gland. The fat of the lactating gland is almost intermediate in character between butterfat and body fat as judged by the 3 constants of fat; the I number, the Reichert-Wollney number and the saponification number. The organic P and cholesterol content of 2 lactating glands were too low to warrant their consideration as related to milk fat. From the data it can be concluded that the fat in the mammary gland of lactating cows is concerned in the synthesis of the milk fat.—*A. H. Frank.*

942. **PETERSEN, W. E., L. S. PALMER, and C. H. ECKLES. The synthesis and secretion of milk fat. III. A study of activity of the perfused surviving gland, with special reference to the fat.** *Amer. Jour. Physiol.* 90(3): 592-599. 1929.—Five mammary glands (cow) were used in a perfusion experiment with various modifications of an isotonic saline solution. Perfusion failed to cause secretion of milk fat calculated to be in the gland. While the fat content of the post-mortem milkings was small, microscopic examination revealed a normal distribution of large and small fat globules. This together with failure to find free fat particles in alveoli is taken as evidence against the hypothesis that the increase in

fat with the progress of milking is due to physical retardation of the fat particles by smallness of the ducts. Perfusing corn oil emulsion through 4 glands failed to cause an increase in the fat content of the resulting secretion. Microscopic sections of glands perfused with colored emulsion showed fairly uniform coloration of the fat cells indicating its capability of being deposited in the fat cells of the gland. Chemical analysis of the extracted fat from 2 glands showed that the volatile fatty acids, as shown by the Reichert-Wollney number, were increased by perfusion to that of practically normal butterfat.—*A. H. Frank.*

944. RAAB, ERNST. Über die Rest-N-Fraktion des Scheidensekretes bei Fluor. *Arch. Gynäkol.* 134(3): 519-545. 1928.—The vaginal secretion after fluoride contains 2-7% albumin, and products of protein autolysis. Of the amino acids, tyrosine, histidine, and arginine are found. Tryptophane cannot be demonstrated and the ether-soluble fraction of the xanthoproteic reaction is small. The secretion varies in pH from 4.2 to 6.4, and when acid the autolysis is due to pepsin-like ferments from the dead cells. When alkaline the autolysis is like that of a peptidase, and the enzymes come from leucocytes. Protein digestion by bacteria plays a subordinate rôle. The lactic acid of the secretion is an essential factor for intensive proteolysis. The urea is high and must be considered as a transudate. It is probable that there is a current of fluid through the vaginal epithelium into the vagina.—*M. E. Collett.*

946. ROSSENBECK, H. Wann tritt die Geburt ein? (Tierexperimentelle Studien zur Frage nach den Ursachen des Geburtseintrittes.) *Arch. Gynaekol.* 140(1): 141-180. 1930.—The musculature of the pregnant uterus of the rabbit in different gestational stages was examined pharmacologically and found to be influenced by extracts of the posterior lobe. The contraction of the musculature at different stages in the gestation period forms a characteristic curve by which the time of parturition can be predicted and seems to be an expression of the optimum concentration of the posterior lobe hormone.—*H. Rossenbeck (transl. by C. S. Simkins).*

947. RUNGE, H., M. BAUR, und H. HARTMANN. Zur Physiologie und Pharmakologie des Nabelschnurkreislaufes. I. *Arch. Gynäkol.* 134(3): 626-642. 4 fig. 1928.—The pressure in the umbilical vein is higher than in the systemic veins, but is only one half the pressure in the umbilical artery. The theoretical means of nourishing Wharton's jelly are: (1) Through the amnionic fluid; (2) Through the walls of the large umbilical vessels. The wall of the umbilical artery is impermeable to both colloids and highly soluble dye-stuffs. But since soluble dyes pass through the wall of the umbilical veins in both directions, the rate varying with the pressure, the interchange of soluble substances between the amnionic fluid and umbilical vein is possible.—*S. N. Blackberg.*

948. SCHOEDEL, JOHANNES. Erhaltungswert und Erhaltungsmöglichkeit kleinster Frühgeburten. *Jahrb. Kinderheilk.* 129(3/4): 143-152. 1 fig. 1930.—Schoedel reports 5 cases of premature infants, weighing at birth 800-1000 gm. and measuring 33-38 cm., but living and healthy at 2-18 mos. He has been able to establish the complete normality later in life of many children who at premature birth weighed 1000-1500 gm.

949. SCHOTT, R. G., and W. V. LAMBERT. The normal variability of the sex-ratio in the guinea pig. *Iowa State Coll. Jour. Sci.* 4(3): 343-349. 1930.—The sex-ratio observed in a colony of 2,014 guinea pigs was 49.45 ± 0.23% males. The observed sex-ratio is slightly lower in summer than in winter, but does not vary consistently from month to month. Age of sire, age of dam, size of litter, interval between litters, and sequence of litters had no effect upon the sex ratio. A differential mortality rate between the sexes, from birth to the 15th day, and from 15 days to 30 days, is not supported by these data. No ordinary environmental factor appears to have even a slight specific effect on the sex-ratio in the guinea-pig.—*Authors' summary.*

950. SCHRUMPF, AUGUST. En undersøkelse av kvinners hemoglobinmengde før og efter partus. [An investigation of the hemoglobin content in the blood of pregnant women before and after birth.] *Norsk. Mag. Lægevidensk.* 91(3): 311-322. 1930.—Schrumpf describes earlier investigations which show great differences; a short description of the various methods for quantitative determination of Hb follows, and their reliability is discussed. He then tabulates 1506 Hb analyses carried out at the Krohgstötten hospital, Oslo. The tests were performed with a Hellige hemometer with glass prism, the correcting factor of which as to absolute Hb values has been determined upon control analyses of the O capacity from 2 blood samples. In more than 75% of the total number the Hb concentration before delivery is decreased compared with the normal content (116 analyses upon nurses and ♀ students found to av. 0.142). During delivery the average Hb concentration is reduced from 0.124 ante partum to 0.119 post partum. The reduction was much greater in cases with hemorrhage of more than 100 gm. accompanying birth. More than 60% of the ante partum, more than 65% of the post partum tests and more than 80% of the post partum analyses with hemorrhage show the Hb concentration reduced below the normal minimum 0.130. The reduction of the Hb concentration after delivery seems to be greater for the ages 16-25 yrs. than for the ages 26-35, while the reduction post partum seems to be more distinct for the ages 26-35 when hemorrhage followed the birth. Average Hb concentration ante partum, where no hemorrhage took place is slightly higher than the ante-partum-value for cases with hemorrhage. Schrumpf is inclined to connect the Hb reduction where it is found during pregnancy and birth partly with the increase of plasma, but especially with the loss of Fe to the child. He recommends the treatment with Fe of women before and after birth where their Hb concentration is much reduced. He also suggests that the "Oligosidérémie des enfants" during the first ½ yr. of milk nourishment might be the result of an anemia of the mother.—*Author's summary.*

951. SERGIJEWSKY, M. W., und J. R. BACHROMEJEW. Über die Wirkung des Prostatasekrets auf die Spermatozoen. Einfluss des Reizes der sekretorischen Nerven (Nn. hypogastrici) auf die aktive Reaktion des Prostatasekrets. *Zeitschr. Ges. Exp. Med.* 71(3/4): 303-313. 1930.—Data of 9 experiments are reported. The prostatic secretion of dogs (number not stated) obtained by stimulation of the hypogastric nerves by the method of Mislawsky and Bormann, showed a variable pH. Protracted stimulation of the hypogastric nerves as well as introduction of pilocarpin altered the secretion from its original neutrality (pH 7) to marked acidity (pH 2.5 and even 2). In spite of the great difference in reaction, energetic movement of the spermatozoa was present in all the samples, but in the more acid ones (pH 6-2.8, etc.) the strings of semen showed an early tendency to clump together and the motion therefore gradually ceased. Hence it appears that the activation of the motility of the spermatozoa by the prostatic secretion depends upon a specific substance contained in that secretion. The reaction of the secretion, however, is of great importance for the maintenance of the life of the spermatozoa. The viscosity of the secretion at the beginning of the study amounted to 1.1, and changed very little (1) or not at all during the course of the study.—*Authors' summary (transl.).*

953. **STUART, C. A., and A. M. BANTA. Available bacteria and the sex ratio in Moina.** *Physiol. Zool.* 4(1): 72-86. 1931.—The numbers of bacteria available as food for Cladocera in different make-ups and dilutions of manure solution used in culturing these animals were found by counts (employing methods of water analysis) to be exceedingly variable. Hence, in attempting to test the effects of different numbers of bacteria as available food, a filtrate low in bacterial numbers but capable of keeping both introduced bacteria and Cladocera alive was used. To this filtrate in 10-milliliter quantities was added a bacterial suspension in definite amounts: 1, 1/5, 1/10, 1/15, 1/25, 1/50, 1/100, and 0. Young sister *Moina* reared (3 in each container) in such bacterized media produced only female young in the 1 concentration; mostly females, but in some cases also a few males, in the 1/5 concentration, on the average 7% males (70 experiments); and averages of 10, 26, 47, 60, 53, and 44% males in the 1/10, 1/15, 1/25, 1/50, 1/100, and 0 concentrations of bacterized medium, respectively. As sisters were used in each of these experiments and as cultural conditions, other than quantity of available bacteria, were maintained as nearly uniform as possible, quantity of food appears as a factor in control of sex in *Moina macrocopa*. Observations on time of release of young produced indicate that, as in experiments with crowding, low temperature, and treatment with certain drugs, male production is associated with a lowered rate of the mothers' development, but that when this rate of development is excessively lowered (as in the 1/100 and 0 concentrations), male percentage falls off.—*Authors* (*courtesy Wistar Bibl. Serv.*).

954. **STUART, C. A., MAURITA McPHERSON, and H. J. COOPER. Studies on bacteriologically sterile Moina macrocopa and their food requirements.** *Physiol. Zool.* 4(1): 87-100. 1931.—A method is described by which *Moina macrocopa* mothers may be rendered bacteriologically sterile by sufficiently prolonged and repeated washings in autoclaved pond water. Bacteriological methods for testing sterility of washed mothers are discussed in detail. Bacteriologically sterile Cladocera were used in a study of the relative food merits of sterile soluble proteins, protein débris, dead bacterial bodies, and living bacterial cells for *Moina macrocopa*. Young, bacteriologically sterile *Moina* mothers placed in sterilized distilled water and sterilized tap-water died without showing any perceptible growth and without releasing any young. When placed in sterilized pond water, manure infusion, a sterile Berkefeld filtrate of manure infusion, or in sterile bacteriological broth, bacteriologically sterile mothers all showed signs of growth and many released young. In these media growth of the Cladocera could not be prolonged beyond one generation, but the addition of dead bacterial bodies increased their nutritive value slightly. Bacteriologically sterile mothers reared in sterilized manure infusions bacterized with living organisms of *Escherichia* and *Aerobacter* thrived as well or better than sterile-sister mothers in the usual culture medium-manure infusions. All species of bacteria do not serve equally well as food for *Moina* mothers. Many highly pigmented strains of bacteria from the genera *Chromobacterium* and *Serratia* proved exceedingly toxic for Cladocera.—*Authors* (*courtesy Wistar Bibl. Serv.*).

955. **TACHIBANA, T. Pregnancy and autolysis of the ovaries and the uterus.** *Japanese Jour. Obstetr. and Gynecol.* 13(1): 69-72. 2 fig. 1930.—Using an unspecified number of ♀ rabbits, by the method of Rona and Mislowitzer, Tachibana found the autolysis of ovaries and uterus most active at pH 3-4; autolysis of ovaries very slightly decreased in pregnancy and puerperium; autolysis of uterus markedly increased in pregnancy and at the beginning of the puerperium, approaching normal in a few days.

956. **VOGEL, HERBERT. Über den Einfluss der Sexualorgane auf die sportliche Leistung des Mannes im Training. (Vorläufige Mitteilung.)** *Arbeitsphysiologie* 3 (3): 250-253. 2 fig. 1930.—A daily record of the performance of athletes in training showed that the minimum occurred within a few days after a nocturnal emission.—*T. Organ.* 122(3): 584-592. 4 fig. 1930.—The evidence from unilateral castrations of male mice and guinea-pigs shows that there is no extrahormonal relationship between the gonads and secondary sexual characteristics.—*C. S. Simkins.*

958. **WEICHERT, CHARLES K. Effect of experimental hyperthyroidism on reproductive processes of female albino rats.** *Physiol. Zool.* 3(4): 461-466. 1930.—Feeding of desiccated thyroid gland to normal and pregnant albino rats had a decided effect on the reproductive processes. Pregnant rats fed 0.25 gm. of desiccated thyroid daily, beginning on the 5th day after conception, either died, resorbed their fetuses, or delivered after a prolonged gestation. If the fetuses were delivered, they were either born dead or died shortly after birth. Another series of pregnant rats fed 0.5 gm. of desiccated thyroid daily, beginning on the 5th day after conception, gave similar results, but the reactions were more severe. Normal rats which had shown regular estrous cycles were fed daily with 0.25 gm. desiccated thyroid. The animals had, on the average, 2.1 regular cycles, after which the vaginal smears presented a typical diestrous picture. The diestrus persisted as long as thyroid feeding was continued. The animals came into estrus, on the average, 6 days after thyroid feeding was discontinued. Study of sections of the ovaries of some of these rats suggests that inhibition of estrus may be due to persistent corpora lutea. The inhibition of estrus, the prolongation of gestation, and the death of the fetus in utero, all suggest that the anterior lobe of the pituitary body may in some way be involved. A thyroid-pituitary-gonadal mechanism is suggested.—*Author* (*courtesy Wistar Bibl. Serv.*).

959. **WILKINSON, P. D., and V. E. NELSON. Diet in relation to reproduction and lactation. III.** *Amer. Jour. Physiol.* 96(1): 139-145. 1931.—[Feeding experiments (number not stated) indicate that] rats grow at a normal rate with 10, 20, 40 and 73.3% of soy bean as the only source of vitamins B and G. Reproduction was normal on the lower levels of soy bean, but on the higher levels the rats were not so prolific as on the lower levels. Satisfactory lactation was not obtained on any level of soy bean investigated. Lung and spleen from hogs and beef thymus did not supplement a 15% level of Virginia soy bean so as to improve lactation appreciably. Hog pancreas and pancreas, brain, and heart from cattle, supplemented the soy bean ration so an improvement in lactation was apparent. Liver from hogs and cattle and hog kidney supplemented the soy bean ration in such a way that very marked improvement in lactation resulted. The young showed a superior rate of growth. The lactating factor was destroyed in liver at 120° C. Ether extract of liver possesses no appreciable lactating properties, but the residue does.—*Authors' summary.*

960. **WILSON, P. T., and H. E. JONES. A study of like-sexed twins. I. The vital statistics and familial data of the sample.** *Human Biol.* 3(1): 107-132. 1931.—In a school enrollment of 75,000, 1051 individual twins were located. This is close to the expected number (on the basis of the frequency of plural births) if allowance is made for the relatively high death rate of twins. The 471 pairs with both members living consisted of 28% ♂♂, 39% ♀♀ and 33% ♂♀. Data from 212 pairs, selected as a sub-sample, were secured by means of a standardized interview with the mothers. Following the method used by Siemens and others, these pairs were classified as 94 identical and 97 fraternal, with 21 "undetermined." The average age of parents at the birth of the twins showed

no difference for the different types of pairs. In comparison with a control group the mothers showed only an average fertility in terms of the number of pregnancies. About ¼ of the fruitful pregnancies resulted in the birth of twins. In relation to length of pregnancy there were indications that identical twins are the more apt to be born "before expected." Interview data concerning fetal membranes failed to give reliable results. The average birth weight of the individual twins was about 6 lbs. There was no reliable difference between identical and fraternal or first and second born; the males weighed more than the females. The fraternals showed slightly more intra-pair differences in birth weight than the identicals; but when these differences were computed in relation to the total weight of each pair the differences became statistically unreliable.—*P. T. Wilson.*

962. **YOCHEM, DONALD E. Spermatozöon life in the female reproductive tract of the guinea pig and rat.** *Biol. Bull. Marine Biol. Lab.* [*Woods Hole, Mass.*] 56 (4): 274-297. 1929.—The author studied the duration of life of spermatozoa in different portions of the female tract of 13 guinea pigs and 14 rats after normal matings. Similar studies were made of the spermatozoa artificially injected into 11 guinea pigs and 6 rats at oestrum and 23 guinea pigs at the interoestrous period. It was found that motile sperm were in the uterine horns and oviducts of guinea pigs 41 hrs. after normal mating, and in rats 17 hrs. after mating. In the cases of insemination during oestrum, motility was maintained for 41½ hrs. in guinea pigs and 12½ hrs. in rats. The duration of life of sperm artificially injected at the interoestrous period was 36 hrs. in guinea pigs. There was thus no physiological difference in the uterus at oestrum and interoestrum which could be detected in the life of the spermatozoa. However, injections of sperm of rats into guinea pigs survived but 4½ hrs. and guinea pig sperm injected into female rats survived but 11 hrs. It thus appears that a foreign uterus has a marked effect upon the destruction of spermatozoa.—*G. Haines (courtesy Exp. Sta. Rec.).*

963. **ABRAMSON, ERNST. Über Muskelkraft und technische Fertigkeit während und nach einer Trainingsperiode.** *Arbeitsphysiologie* 2(2): 148-162. 3 fig. 1929.—A number of subjects were trained to muscular work on Johansson's apparatus or to precision work which consisted of threading needles. In one experimental period of about a month, several subjects trained once a day, others twice a day. After stopping the training the falling off of the performance was followed for a year. The muscular skill gained by training fell off at first quickly and later more slowly, and the greater the skill obtained by training, the greater was the falling off. After a year, the subjects were at a common level independent of the level they had reached at the end of the training period. In training, the work should not be continued to exhaustion, if one desires to obtain good results. With precision work, the skill obtained persists longer and remains upon a higher level than the increase of strength. High technical skill cannot be obtained without special aptitude. A person with natural aptitude will acquire a greater skill than one with poorer ability but more training. In order to reach a high degree of muscular performance, training is of more importance than natural ability. The subjective feeling of capacity for work is often misleading.—*T. M. Carpenter.*

964. **BENAZZI, MARIO. Manifestazioni quantitative della rigenerazione negli insetti. [Quantitative data on regeneration in insects.]** *Riv. Biologia* [*Milano*] 11 (5/6): 625-631. 1929.—Investigators have shown that, within certain limits, the velocity of regeneration increases with the size of the lost part. In the larva of the dragonfly, *Aeschna grandis,* the quotient of growth in a regenerating tarsus (comparing the length of the tarsus in the instars prior to and following the removal) is progressively greater if instead of the tarsus alone, the tibia also is removed, or both tibia and femur.—*M. Benazzi (transl. by R. A. Muttkowski).*

965. **BIRD, CHARLES. The effect of maturation upon the pecking instinct of chicks.** *Pedagogical Seminary & Jour. Gen. Psych.* 33(2): 212-233. 1926.—Chicks develop rapidly within the first 18 hrs. after hatching, passing from a stage in which the erect posture is impossible and all overt movements are performed very slowly and with great incoördination to one in which walking is regular and the pecking reactions, though not perfected are more integrated. Measures of pecking show that along with the development proceeding with age there occurs a marked decrease in the errors of missing the grains and a statistically significant increase in the average number of hitting and swallowing reactions. A control group of chicks, which lacked practice when first tested at 30 hrs. of age, was as accurate as another group of equal age which had had a very slight amount of practice. Both of these groups were more accurate than another group which was tested when about 8 hrs. old. It is probable, therefore, that the factor which accounts for the differences in accuracy existing between the 1st and 2nd day chicks is not practice but the physiological development or maturation which proceeds with age. Other measures of objectifying pecking than the 4 which have been generally accepted, such as the type of the first reaction to grains and the average trail in the series on which a swallowing reaction occurred, likewise indicate that chicks 30 hrs. old are superior to the 8 hr. old group. The amount of time required to complete the 25 trials yields no certain differences between newly-hatched and older chicks. There is, however, a moderately high correlation between the time required on the 1st and 2nd days. Maturation is much more effective during the first 2 days than later.—*Author's summary and conclusions.*

966. **BUCHANAN, J. WILLIAM. The nature of disintegration gradients. I. The significance of a gradient in susceptibility to distilled water in Planaria.** *Jour. Exp. Zool.* 57(2): 307-330. 1 fig. 1930.—The disintegration of *P. dorotocephala* in distilled water discloses an anteroposterior gradient in susceptibility. The rate of disintegration in distilled water increases with increase in hydrogen-ion concentrations. Animals in small volumes of distilled water disintegrate more rapidly than do animals in large volumes. Disintegration by high temperature is more rapid in distilled than in tap-water. Previous exposure to distilled water increases the susceptibility to high temperature. During the early period of exposure to distilled water the animals tend to lose weight. Later, the weight increases, and just before disintegration begins the animals are greatly distended. Distilled water does not materially affect the rate of O consumption of the animals during the early period of exposure. At or about the time of distention and the initiation of disintegration the rate of O consumption is distinctly lowered. The evidence indicates that the toxicity of distilled water is due to the excessive imbibition of water by the organism and is independent of its

effect on respiration. This disintegration so closely agrees with and parallels the respiratory gradient as to indicate that both are features of the anteroposterior differential in physiological activity.—*Author* (*courtesy Wistar Bibl. Serv.*).

967. **BUCHANAN, J. WILLIAM. The nature of disintegration gradients. II. The effect of hypertonic solutions on the disintegration of Planaria by high temperatures.** *Jour. Exp. Zool.* 57(3): 455-472. 1930.—By exposing animals to high temperature in tap-water and in Ringer's solution it is shown: That hypertonic solutions prevent the disintegration following death due to high temperature. There is no evidence that such solutions afford any protection against the lethal action of high temp. It is also indicated that the disintegration gradient in tap-water represents an anteroposterior gradient in water appropriation that is not directly dependent on differences in rate of respiration. A mechanism of this type is essentially quantitative in action and provides for a differential in rate of interchange between the several regions and their environment.—*Author* (*courtesy Wistar Bibl. Serv.*).

968. **CHILD, C. M. The physiological gradients.** *Protoplasma* 5: 447-476, 1929.—The article is a review of the work by Child and others.—*W. Seifriz.*

969. **FISCHEL, WERNER. Die tierischen Gedächtnisleistungen.** *Biol. Zentralbl.* 49(5): 291-301. 1929.—A method is suggested for grouping the memory accomplishments of animals so that some conclusion may be reached as to their relative perfection and as to what use different animals can make of impressions from without. A review of the literature dealing with the learning ability of animals is given and the rôle of memory in this is discussed. A distinction is drawn between "Free Memory" and "Controlled Memory," the former operating in the absence of the stimulus, the latter only when it is present. Likewise "Simple Associations" are distinguished from "Compound Associations" by the fact that the first imply choice, while the latter do not. Training may be "Positive" (reward) or "Negative" (punishment or lack of reward) or "Combined" (reward and punishment). According to these definitions: 1. Annelids, Molluscs and Crustacea, with the exception of the Decapoda, are capable of only "Simple Associations" and "Controlled Memory." 2. *Aeschna* larvae, Dytiscidae and Decapoda (?) have "Compound Associations" but are still capable only of "Controlled Memory" and must be trained by the "Combined" method of reward and punishment. 3. Higher insects and probably all vertebrates are capable of "Compound Associations" and may be trained by "Single" methods either positive or negative. 4. There have been as yet no systematic studies on "Free Memory" but it is assumed in Bees, occasionally in Mice, in certain Birds and in Apes. The author believes that it is in this field of "Free Memory" that the best results will be obtained towards the solution of the problems of animal behavior.—*P. H. Yancey.*

970. **HUNTER, WALTER S. The behavior of the white rat on inclined planes.** *Pedagogical Seminary & Jour. Gen. Psych.* 34(2): 299-332. 1927.—When the white rat is placed upon an inclined plane, under the conditions of the present experiment, it responds more often negatively than positively to gravity. This is true just before and after the eyes open, and it is also true of adults that have been blinded. The present experiments throw no light upon the receptor and neural mechanisms involved in the control of this behavior. The distributions of the angles of orientation (θ) followed by the subjects at the various angles of elevation (α) of the plane cover a wide range. These distributions are multimodal, with the fewest responses in the region of α 40°. Young rats often lose their footing and fall, or slide, off the plane when this is elevated at α 45°, 60° and 70°. No change in behavior was demonstrated which could be correlated with the opening of the eyes. Adult blinds, probably because of their superior muscular strength, crept at smaller θ angles than did the young rats. No single measure of central tendency is adequate to represent the behavior at the various values of α because of the character of the distributions and the number of falls from the plane at the high values of α. It has been possible to confirm Crozier's findings, that there is an apparent linear relationship between mean values of θ and the log sin α and between the cosine of mean θ's and sin α. The value of these findings is negligible, in the present experiment, in virtue of the points made above under (6) and in virtue of the different results when median θ is used or when only the first responses are considered. If the distributions presented in this paper for the behavior of a few rats are applicable to rats in general, we can predict that rats tested under the present conditions will be predominantly negative to gravity. We cannot, however, predict a progressive change in θ concomitant with changes in α.—*Author's summary and conclusions.*

971. **MAINX, FELIX. Untersuchungen über den Einfluss von Aussenfaktoren auf die phototaktische Stimmung.** *Arch. Protistenkunde* 68(1): 105-176. 3 fig. 1929.—The author worked with pure cultures of *Synura uvella, Gonium pectorale, Eudorina elegans,* and *Volvox aureus.* He describes the preparation of the cultures and culture methods. Boiled soil solutions were used as food. The cultures were illuminated 12 hrs. daily by artificial light. In the experiments a powerful lamp in a dark room was used as the source of light and the illumination was reduced by moving the light away. The position of the point of reversal of positive and negative phototaxis under this arrangement was used as a measure of the phototactic state. The state changes in the cultures periodically each day. Allowing for this, the displacement of the point of reversal, which is dependent upon the physiological changes occurring with age in the materials of the cultures, may be kept constant for long periods. Sudden change of certain external factors has a real influence upon the position of the point of reversal. An increase in the pH displaces the point of reversal in high intensities of light, as do also a lowering of the pH in the *Volvocales,* a lowering of the surface tension, and certain anesthetics. In case of displacement of the reversal point in low intensities of light, rise or fall of temperature, and in *Synura* a lowering of the pH, are effective. Light is effective only after a considerable period, and previous illumination displaces the reversal point in lower intensities, and previous stay in the dark displaces it in high intensities. Upon continuation of the state-changing influence, there follows after a time a reversion to the original state, no doubt due to internal regulation. Of particular interest is the fact, that each factor that displaces the reversal point in high intensities concurrently lowers the threshold; and conversely, each factor that produces a displacement of the reversal point in low intensities, causes a rise in the threshold. There is also in the first case an extension of the limits of positive phototaxis in both directions, and in the second case a narrowing of its limits. These facts cannot be brought into accord with the acceptance of one photochemical process as the common cause of positive and negative phototactic movements. The author proposes the theory that positive and negative phototaxis depend upon two different chains of reactions that operate independently and antagonistically, and can be influenced independently of each other by internal and external factors. On the basis of the results of his experiments thus far, the author seeks also to apply his theory to phototropism. The entire botanical and zoological literature of the field is treated by the author in his discussion.—*F. Mainx* (*transl. by W. C. Stehr*).

972. **MAST, S. O. Mechanics of locomotion in Amoeba proteus with special reference to the factors involved in attachment to the substratum.** *Protoplasma* 8: 344-377. 3 fig. 1929.—If specimens of *A. proteus* are transferred to chemically pure water they usually assume a radiate form, protoplasmic streaming ceases and they do not attach; but if they are left several hours they attach and move. The processes associated with locomotion are therefore not necessarily dependent upon substances

in solution in the surrounding water. Amoeba in pure water attaches to all kinds of surfaces tested, common glass, pyrex glass, quartz, paraffin. It attaches to common glass more quickly and firmly than to pyrex glass or quartz, but if a trace of salt is added to the water there is practically no difference, although the time required for attachment is enormously reduced. The difference in the effect of common glass, pyrex and quartz is probably due to difference in their solubility. If the surface of the glass is ground or if the solution is slightly agitated the time required for attachment is decreased and the firmness of attachment is increased. Attachment depends upon the physiological conditfon of the amoeba. In some specimens in a given solution the surface is very much more adhesive than in others in the same solution. All the salts tested (17) greatly decrease the time required for attachment and increase the firmness of attachment. All have the same effect but not in the same concentration. The effect of NaCl and KCl increases very gradually from N/20 to a maximum at about N/100, after which it decreases very gradually until about N/1000 is reached and then very rapidly. The effect of $CaCl_2$ increases rapidly from N/20 to about N/60 then slowly to a maximum at about N/200; after which it decreases very slowly until about N/40,000 is reached and then very rapidly. There is very little difference in the effect on attachment of NaCl and KCl in concentrations ranging from N/40 to N/800 and of $CaCl_2$ in concentrations ranging from N/80 to N/40,000. The effect of $CaCl_2$ is considerably less than that of NaCl and KCl in the stronger and much greater in the weaker solutions tested. All 3 salts however have a definite effect in the weakest solution tested, N/100,000. The effect of a mixture of Na, K and Ca salts is approximately equal to the sum of the effect of the 3 salts each in solution by itself in the concentration which it has in the mixture, i.e., the action of these salts is additive, not antagonistic. It therefore differs from the action observed in many other physiological processes. The action of Na_2SO_4 and K_2SO_4 in various concentrations is essentially the same as the action of NaCl and KCl in the same concentrations. The action of Na_2CO_3 and K_2CO_3 is complicated, owing to change in hydrogen-ion concentration produced by hydrolysis. The non-electrolytes lactose and glycerine do not facilitate attachment of Amoeba, but urea which ionizes slightly and is faintly alkaline definitely favors attachment. The optimum pH for attachment in balanced solution appears to be between 6.6 and 7, but there is remarkably little difference over a very wide range, i.e., from pH 4.6 to 8.2. The favorable effect common to salts and urea on attachment of Amoeba must be associated with some common property, probably the electric charge carried by the ion. The difference in the effect of different salts of the same concentration is probably due to diversity in their action on the physiological condition of the amoebae. Salts appear to effect attachment in two ways: (a) by action directly on the surface, probably resulting in a change in the electric charge owing to selective adsorption; (b) by changing internal processes, owing to adsorption and diffusion. Locomotion is dependent upon attachment but the rate of locomotion is largely dependent upon the rate of sol-gel transformation and the difference in the elastic strength of the plasmagel at the two ends and only slightly if at all upon conditions of attachment.—*Author's summary.*

973. NOMURA, EKITARO, and SHINRYO OHFUCHI. Effect of inorganic salts on photic orientation in Allolobophora foetida (Sav.). V. Sodium salts—Na_2SO_4, $NaNO_3$, and NaCl. *Sci. Rept. Tôhoku Imp. Univ. 4th Ser. Biol.* 5(3): 467-483. 1930.—The experiments were carried on by submerging the worms in a solution of the single or mixed Na salts. In the ventral nerve cord, $NaNO_3$ and NaCl caused a weakening of positively orienting function, while Na_2SO_4 caused a strengthening at first and then a weakening. In the brain, $NaNO_3$ caused a weakening, NaCl a strengthening, and Na_2SO_4 a strengthening at first and then a weakening, of negatively orienting functioning. In $Na_2SO_4+NaNO_3$, the change in positive orientation tended mainly to follow that of the worms placed in $NaNO_3$, while the change in negative orientation showed a tendency between those occurring in Na_2SO_4 and $NaNO_3$ separately. In Na_2SO_4 +NaCl, the change in positive orientation tended mainly to follow that in NaCl, but the change in negative orientation appeared to follow neither that in Na_2SO_4 nor in NaCl. In $NaNO_3$+NaCl, the change in both orientations tended mainly to follow that in $NaNO_3$. In all the single and mixed solutions, backward crawling appeared to be caused mainly by a relative weakening of forward crawling functioning in the ventral nerve cord. Winding movement might be more or less pronounced.—*Authors' abstract.*

974. PEEBLES, FLORENCE. Some growth-regulating factors in Tubularia. *Physiol. Zool.* 4(1): 1-35. 1931.—Experiments on isolated stems of *Tubularia mesembryanthemum* and *T. crocea* indicate that the extent of growth of new structures is definitely related to metabolic activity of the individual. Removal of the hydranth from the distal end of a stem brings about changes in the entire length, and after successive removal of hydranths they decrease in size. On ligatured stems the first oral hydranth is always larger than the first aboral hydranth, but successive oral and aboral hydranths are usually of equal size. Ligatured stems show rhythm in the rate of development, the first hydranths appearing in 2 days, the 2nd in 1, and the 3rd in 3 days. Hydranth formation on the apical end of isolated stems is determined by the 6th hr. If at the end of this time a short piece is removed from the cut end, it behaves as a part of the long piece, producing a full-sized head. If removed 2-4 hrs. after isolation of the stem, it produces a small hydranth, this behaving like a short piece. Length of the apical primordium in half stems is an expression of the level of the piece rather than of its volume. Growth in length of new hydranth stalks is greater on proximal than on distal pieces. Size is not a safe criterion in determining age of a stem. At the breeding season all stems become physiologically young.—*Author (courtesy Wistar Bibl. Serv.).*

975. WATANABE, YISAMU. On the physiological axial gradients of chaetopod annelids. I. Types of axial gradients examined by onset temperature of heat shortening. *Sci. Rept. Tôhoku Imp. Univ. 4th Ser. Biol.* 5: 153-213. 1930.—In chaetopod annelids the onset temp. of initial heat-shortening is different in different parts of the body or body wall and varies in the form of an axial gradient along the axis of body. Among the forms of heat-shortening gradients in chaetopods, there are 4 different types. Two are known respectively as the monopolar and bipolar types or the primary and secondary types of chaetopod gradients, while the others are quite different from these and are termed the 3rd and 4th types, respectively. The 3rd type resembles an inverted image of the bipolar type, that is, the onset temp. is highest at about the middle part decreasing gradually towards both extremities, having one maximum and two minima. In the 4th type, the onset temp. is also highest at about the middle part and gradually decreases towards both ends of the body, but near the posterior end is lower than in the anal segments and increases again at the very end, so that the 4th type is more complex than the other 3, having 2 maxima and 2 minima. The 4 types of heat-shortening gradients were noted and each type was found to be specific and characteristic for each species. Although in general the different groups of chaetopods show characteristic types of gradients, owing to the presence of exceptional cases, the causal connection of different types of gradient with phylogenetic advance of chaetopods cannot be too strongly emphasized until the heat-shortening gradients in embryonic or younger larval stages are examined with respect to possible transformation of the gradient type during growth. The heat-shortening gradient is closely correlated with those of the content of solid constituents and the electrical potential, the 2nd of

which, in turn, is, according to other investigators, related to the metabolic rate.—*Y. Watanabe.*

976. **WERMEL, JULIUS. Über den Einfluss der Regeneration und Überernährung auf die Siphonenlänge bei Ciona intestinalis L. (Ein Beitrag zu Kammerers Experimenten).** *Arch. Entwicklungsmech.* 122(1): 22-47. 4 fig. 1930.—The investigation was intended to solve the discrepancy between the experiments of Mingazzini and Kammerer and those of Fox, but as the later experiments were made on the Murman coast of the Arctic Ocean, the exact conditions of the original experiments were not maintained. Therefore the results did not fully coincide with either Kammerer's experiments (the siphons not growing longer after a single section) or those of Fox (siphons not growing longer under overnutrition). At any rate Kammerer's results were not refuted by those of Fox. The work was performed with more precise methods than those used by the previous authors.—*J. Wermel.*

978. **BEDNÁR, MARCEL, und OTTO LANGFELDER. Über das intravenöse (hämatogene) Riechen.** *Monatsschr. Ohrenheilk. u. Laryngo-Rhinol.* 64(10): 1133-1139. 1930.—Certain substances elicit the typical sensation of smell after intravenous administration. After obliterating the sense of smell in the nostrils with paraffin oil, 14 normal subjects and 6 with nasal diseases were tested with neosalvarsan, "camphaquin," and "caseoterpol." Between the beginning of the injection and olfaction there is a latent period corresponding to the time necessary for the injected material to reach the olfactory region by the blood routes. Subjects with anosmia caused by paralysis of the sensory nerves or by atrophy of the mucosa showed no hematogenous olfaction, while it was intact in respiratory anosmia. Hematogenous olfaction occurs by intramucous stimulation of the ends of the olfactory nerve.—*From authors' summary (transl.).*

979. **CHAFFEE, E. L., and EVELYN SUTCLIFFE. The differences in electrical response of the retina of the frog and horned toad according to the position of the electrodes.** *Amer. Jour. Physiol.* 95(1): 250-261. 1930.—The electrical responses from the horned toad's retina are either positive or negative, depending upon the position of the grid electrode. The negative responses are obtained when the grid electrode makes contact with the retina in a band which extends across the eye just above the pecten and blind spot. The negative responses are similar to the positive responses inverted except that the flat region between "on" and "off" effects is always negative. Responses, part positive and part negative, can be obtained on the borders between regions. Oscillations are present on the "on" effects from the positive regions but are less marked than in the responses from the frog's retina, probably because they are more rapid and less easily resolved.

980. **CLARK, LEONARD B. Some factors involved in the reaction of insects to changes in luminous intensity. Shock reactions in Dineutes assimilis.** *Jour. Exp. Zool.* 58(1): 31-41. 1 fig. 1930.—Specimens with the parts of the eye on one side covered, when placed in a beam of light on a suitable background, perform circus movements for a time, after which they go in a straight path diagonally across the beam. A sudden change in intensity of the light causes the insect to turn either toward or from the source of light. This response depends upon light from the background. It is suggested that the elimination of circus movements is due to light adaptation progressing to such an extent that some of the ommatidia of the posterior portion of the eye are no longer stimulated and that the response to change of intensity is due to the change in number of ommatidia stimulated in this portion of the eye.—*Author (courtesy Wistar Bibl. Serv.).*

981. **DUKE-ELDER, W. STEWART. The nature of the vitreous body.** *Brit. Jour Ophthalmol.* 14(Monograph Suppl. IV): 5-72. 1 pl. 1930.—Evidence is brought forward which suggests: 1) that the vitreous body is a hydrophilic, elastic gel; 2) that it is formed upon the basis of special protein constituents elaborated by the surrounding ectoderm, and that the common intra-ocular fluid (which is a dialysate of the capillary blood), percolates these, combining with them physically to form a gel; 3) that the reactions of the vitreous body to changes in its environment and in its internal economy proceed along physico-chemical lines according to the conditions which govern the behavior of gels in general. Inasmuch as the vitreous body is not a tissue but a cell product, its reaction to metabolic or toxic disturbances will be passive. It will respond to alterations in its environment or in its internal economy by changes involving swelling (turgescence) or shrinkage (deturgescence). A state of turgescence will tend to bring about a condition of hypertension in the eye, while a state of deturgescence or liquefaction will tend to bring about a condition of hypotension. One of the 1st results one should expect from disturbances in its economy will be its liquefaction with the separation of part of its colloid basis to form appearances evident clinically as opacities. It may be noted that the zonule has a structure similar to that of the vitreous body: it is a gel and the complex systems of fibers which are apparent on histological examination are, like the "fibers" of the vitreous body, artifacts of fixation.

982. **EBBECKE, U. Über eine neue Nachbildphase, das positive Hellbild.** *Pflüger's Arch. Ges. Physiol.* 221 (1/2): 189-197. 2 fig. 1929.—When the usual after-images from strong stimulation (positive dark image and negative bright image) are no longer producible, after-images appear having reversed relationships: a too extended peripheral "reparation" depresses the excitation of the image more than that of the ground (pure peripheral negative dark image); central compensation for the same through increasing of the image, diminishing of the ground. Illumination now causes compensation to continue, the image increases, appearing brighter than the diminishing ground (centrally produced positive bright image).—*Schaefer (transl. by P. A. Moody).*

983. **EBBECKE, U. Über spontane Nachbildschwankungen und das Verhältnis von Nacherregung und Induktion.** *Pflüger's Arch. Ges. Physiol.* 221(1/2): 198-212. 3 fig. 1929.—Pure negative after-images or those fluctuating between negative and positive are explicable upon the basis of local adaptation. With very weak light stimuli, when only pure negative after-images are observed, a retinal after-excitation, which yields a positive after-image, is not present. Fluctuation between positive and negative after-image is founded on a competition between peripheral after-excitation and central compensation (adaptation). Both disappear at the conclusion of stimulation, though in differing tempo. So now retinal, now central excitation may predominate, a positive after-image changing into a negative; the outcome depends upon length of stimulation, strength, general illumination and individual factors.—*Schaefer (transl. by P. A. Moody).*

984. **ENGELKING, ERNST. "Grund" und "Figur" in ihrer Bedeutung für das Farbensehen der anomalen Trichromaten.** *Albrecht Graefe's Arch. Ophthalmol.* 121(3):

479-496. 1929.—Normal deuteranomalous and protanomalous trichromats were tested with an apparatus in which a small opening within a figure (maltese cross or Latin B) or in the gray background of that figure, exposed to view a portion of an adjustable, rotating sector disk bearing red and green sectors. At the beginning of each experiment background and disk were so adjusted as to present a uniform gray surface to foveal vision. The size of the red, or of the green, sector was then increased until the subject could distinguish in peripheral vision red, or green. The results were expressed in terms of sector degrees, indicating the threshold by which the amount of the one color or of the other must be increased for discrimination. The threshold was found to be higher within the figure than in the surrounding ground. The quotient F/G (F: threshold in figure; G: threshold in ground) always exceeded 1. In anomalous trichromats, especially deuteranomalous, the quotient was considerably higher than normal. In the former the figure interfered with color discrimination more than it did in the normal trichromats and hence form perception would seem to be stronger than color sensitivity in anomalous trichromats. Possible bearing of the results upon Gestalt Psychology is discussed.—*P. A. Moody.*

985. FRIEDMANN, W. L. Eine neue Theorie des Gehörmechanismus. I. *Monatsschr. Ohrenheilk. u. Laryngo-Rhinol.* 64(12): 1468-1471. 1930.—The basic difference between Friedmann's and Helmholtz' theories of sound conduction is that the former ascribes to molecules of dissolved gases (in the fluid of the labyrinth and in the adjacent blood and bone tissue) the principal rôle in the conduction of sound to the ends of the auditory nerves.

986. GRANIT, RAGNAR, et al. Comparative studies on the peripheral and central retina. II. RAGNAR GRANIT, and PHYLLIS HARPER. Synaptic reactions in the eye. III. RAGNAR GRANIT, and WINONA von AMMON. Some aspects of local adaptation. *Amer. Jour. Physiol.* 95(1): 211-228; 229-241. 1930.—II. Using the flicker method as a quantitative measure of the intensity of the visual process the authors studied the influence of size of area stimulated, intensity of stimulus and distance between a number of test patches upon the fusion frequency. Their experiments support the view that the retina demonstrates synaptic reactions of the summative type as is to be expected in an organ which not only contains receptors but is also a "true nervous centre." The experiments indicate the approximate validity of the Ferry-Porter law; $n = a \operatorname{Log} I + b$. It is shown that a similar relation holds for the influence of area on fusion frequency and that, accordingly, the fusion frequency n is a function of both these factors, of the form obtained by combining the formulae referring to area and intensity respectively. The variation of fusion frequency with both intensity and area is greater in the periphery than in the centre. This is more pronounced with regard to area, a fact shown to be in agreement with the anatomical differences between the synaptic structures in these 2 retinal areas. The effect of interaction upon fusion frequency has been shown by the fact that several patches stimulated simultaneously give a higher fusion frequency than when each one is stimulated separately. This increases as the patches are brought closer together although the effect may be maximal when the retinal distance between them is as much as 30μ. The interaction met with is interpreted as summation. Central and peripheral retinal areas show only quantitative differences in summative effects. In central vision full spatial effects may be present without impairing the visual acuity. At sufficiently high intensities the fusion frequency for a single patch becomes equal to that for 4 simultaneously stimulated areas. This is interpreted as being due to occlusion. Large areas give higher liminal values of both fusion frequency and intensity. The relative amount of summation and occlusion with different areas and intensities furnishes a simple and rational explanation of these phenomena. III. The rate of local adaptation has been determined by following the drop in fusion frequency of an intermittent light during 6 sec. With central fixation there is little or no local adaptation demonstrable within the period in question. Passing towards the periphery the effect becomes more marked, and from 4° outwards there is a comparatively large drop in critical frequency during the 1st 3 sec. of fixation. The effect gradually diminishes in amount as the time of stimulation is lengthened. The rate of local adaptation is greater with stimuli of higher intensity. It has been found that the rate of local adaptation is determined primarily by the energy per receptor unit rather than by total energy increased by processes of summation in the synaptic layers of the retina. This was likewise shown to be the case in experiments with red and blue light. A greater total amount of energy, however, seemed capable of causing a retardation of the rate of adaptation assumed to be due to more effective charging of the central structures in the retina. In general the effect of red and blue light upon the rate of adaptation was essentially similar. This indicates that with intensities above the range of the Purkinje effect red and blue light must either stimulate both rods and cones or that there is practically no functional difference between peripheral rods and cones with regard to local adaptation. Neither assumption is in keeping with the concept of a complete functional-structural duplicity of rods and cones. It is shown that the former assumption is preferable to the latter particularly on account of its greater conformity to the main facts underlying the duplicity theory. The 1st rapid decrease in fusion frequency with peripheral fixation is assumed to be a rod effect.—*Authors' summaries.*

987. HAMLIN, H. E. Working mechanisms for the liquid and gaseous intake and output of the Jacobson's organ. *Amer. Jour. Physiol.* 91(1): 201-205. 1929.—Air and liquid may be forced out of the Jacobson's organs of rabbits under anesthesia, when their blood pressure is elevated by the pressor effect of adrenalin, as shown by 35 successful demonstrations [on 6 rabbits]. Drops of liquid (secretion) are drawn into the Jacobson's organs of rabbits when the blood pressure recedes following the disappearance of the effect of the adrenalin [8 demonstrations on 2 rabbits]. The results of this research provide another line of evidence in support of the olfactory hypothesis for Jacobson's organ.—*Author's summary.*

988. HECHT, SELIG. The intensity factor in vision and radiation. *Amer. Naturalist* 64(692): 193-219. 1 fig. 1930.—The problem of intensity recognition is considered in terms of its relation to visual acuity. The visual acuity of man and of certain insects has been shown to vary in a specific manner with the intensity of light. These data are quantitatively explained in terms of the suppositions, first that the percipient elements in the eye vary in threshold, and second that visual acuity is proportional to the number of elements functional in a unit retinal area. It is demonstrated that the same suppositions are also capable of furnishing a detailed description of the capacity for intensity discrimination and recognition possessed by the eye.—*S. Hecht.*

989. HERTZ, MATHILDE. Die Organisation des optischen Feldes bei der Biene, I. *Zeitschr. Vergl. Physiol.* 8(5): 693-748. 11 fig. 1929.—Bees are aware of qualitative contrasts between figures and background. They are able, moreover, to distinguish between such figures as a cross and a circle. This differentiation is made not on the basis of the total areas of the figures, or the rectilinear quality, curvature, size or shape, but on the appearance of the figure as a whole—its peculiarities. It was assumed that if a characteristic shape were "learned" by a bee, then its significance and importance in orientation would be maintained unaltered with the transference of the figure to another position. But it was found that a transposition of the "positive" and "negative" figures resulted in the bees' choosing whatever figure lay in the relative position of the previous "positive" figure.—*D. L. Collins.*

990. LASAREFF, P. Untersuchungen über die Ionen-

theorie der Reizung. X. Mitteilung. Über die Gesetze der Verschmelzung der Empfindungen des Flimmerns beim Dunkel- und Hellsehen. *Pflüger's Arch. Ges. Physiol.* 214 (4): 439-448. 1926.—It is established that proceeding from the general form of the ion theory of stimulation, for minimal frequency of light change which gives a continuous sensation, the following formulae may be developed:

$$(n - n_0)(n^2 + a_2^2)^{\frac{1}{2}} = a_1 k J C_0 / R\ (1 - \gamma e^{-a_3 t}), \quad (a)$$
$$e^{pn} = a_1 k J C_0 / R\ (1 - \gamma e^{-a_3 t}), \quad (b)$$
$$e^{pn}(n^2 + a_2^2)^{\frac{1}{2}} = a_1 k J C_0 / R\ (1 - \gamma e^{-a_3 t}), \quad (c)$$

Formulae (b) and (c) agree well with the data of Schaternikoff and Allen. Formula (b) for the relation between n and J has been found empirically by Allen previously.—*Author's summary (transl. by O. W. Richards).*

991. LORENTE de NÓ, R. Untersuchungen über die Anatomie und die Physiologie des Nervus octavus und des Ohrlabyrinths. Vierter Teil. *Arch. Ohren- Nasen- u. Kehlkopfheilk.* 118(4): 241-284. 25 fig. 1928.—The reactions of the semicircular canals on caloric stimulation are very dependent on the position of the head in space. The author attempts to formulate this relationship through complicated mathematical formulae. All the six eye muscles take part in the nystagmus reaction. The strongest nystagmus usually is derived from stimulation of the horizontal canal. The internal rectus generally shows the greatest amplitude of action in the nystagmus reaction. All his experiments demonstrate that the individual semicircular canals are not associated with individual muscles or muscle groups, but with them all. In head positions, where the horizontal canal is vertical, then the vertical canal gives the strongest nystagmus reaction.—*J. E. Lebensohn.*

993. OHM, J. Der vestibuläre Drehnystagmus unter verschiedenen Bedingungen. *Monatsschr. Ohrenheilk. u. Laryngo-Rhinol.* 64(8): 970-977. 1930.—Nystagmographic examination of a man in light and dark, with and without ground or convex glasses, the chair being rotated twice in 12-13 sec., showed that nystagmus with open eyes during rotation had an optical and a vestibular component, and that the optic component could be only partially removed by glasses. Nystagmus is purely vestibular only during rotation in the dark under the conditions given; the subsequent nystagmus appearing in the dark or with ground or convex glasses is also purely vestibular. If the curve of the optic and vestibular factors shows the same frequency but greater amplitude than the curves of optic and of vestibular nystagmus, one would deduce that the optic and vestibular stimuli met in the vestibular nucleus, there being merged into a single nystagmus.—*From author's conclusions (transl.).*

994. RIDLEY, F. The intraocular pressure and drainage of the aqueous humour. *British Jour. Exp. Pathol.* 11: 217-240. 1930.—Experiments are described which were performed upon the dead eyes of pigs, sheep and man and on the living eyes of rabbits. These show that both the dead and the normal living cornea are permeable to salts and diffusible substances, and that this permeability is most marked at the site of the filtration angle. The greater permeability of this area is attributed to the absence of Descemets membrane and it is shown that the freely permeable substantia propria of the cornea extends to the root of the iris. The intraocular pressure exerts a constant hydrostatic force, tending to cause a flow of fluid through the cornea into the conjunctival sac. An examination of the fluids bathing the cornea shows that there is no considerable osmotic pressure opposing this flow and that the physical properties of tears are such as to assist it materially. The corneal drainage path is probably the only one by which aqueous is normally and constantly removed. The sclera is not indistensible. Curves of distensibility are described and their significance discussed. The degree of expansion of which the vascular bed of the uvea is capable was measured and its influence upon the intraocular pressure demonstrated.—*J. Bland.*

995. ROBINSON, ESTHER W., and E. G. WEVER. Visual distance perception in the rat. *Univ. California Publ. Physiol.* 7(15): 233-239. 16 fig. 1930.—Rats are able to ascertain visually whether a path is opened or closed at distances of about 18 inches for albinos and 30 in. for pigmented animals. The capacity suffers a breakdown as the illumination is greatly reduced, but the pigmented animals remain superior at all stages. The ability shown seems to be largely independent of the general activity and learning capacity of the animals as revealed by maze performances in complete darkness.—*Authors' summary.*

996. TUTUI, YOSIMITU. Über das Vorkommen und die Bildung der Ehrlichschen Linie. *Arch. Augenheilk.* 103(3/4): 580-596. 5 fig. (col.) 1930.—The author has studied the appearance of the typical Ehrlich line in a series of animals. He finds that it occurs in practically all the animals investigated (rabbits, rats, fish, turtles, chickens, fox, barn owl, doves, canaries, dogs, cats, screech owl). It is absent in the mouse, carp, the ape and in man. In the mouse its absence is apparently due to the fact that the eye is too small for any difference in temperature to exist in the parts of its anterior segment. It is absent in the carp because the aqueous here contains a thread-like substance which prevents the convection currents. The fluorescein, therefore, sinks to the bottom of the anterior chamber without forming a line. The absence in man and in the ape is to be explained by the very low protein content of the aqueous. As a consequence of this the fluorescein particles are too finely divided to form a definite line.—*F. H. Adler.*

997. YOUNG, JOHN Z. The pupillary mechanism of the teleostean fish Uranoscopus scaber. *Proc. Roy. Soc.* [*London*] *B* 107(753): 464-485. 1 fig. 1931.—In this fish there is a well-developed light reflex. On illuminating one eye, the pupil narrows on this side only; there is no true consensual reflex. However, after cutting one optic nerve, bilateral illumination causes constriction in both pupils. Electrical stimulation of the 3rd or 4th spinal roots, or of the sympathetic chain more anteriorly, or of the long or short ciliary nerves causes narrowing of the pupil. Stimulation of the oculomotor nerves causes dilatation of the pupil. After the animal has been killed by removal of the heart and viscera, the pupils become narrowed; they are released from this constriction by cutting the 3rd and 4th spinal roots, or the sympathetic chains anterior to these roots, or by pithing the cord. They are not released by destruction of the medulla oblongata. There is therefore a cilio-spinal centre, responsible for constriction of the pupil. After unilateral section of the 3rd and 4th spinal roots of the living animal the light reflex is no longer manifested on this side, and the eye is more protruded than the control. After section of one oculomotor nerve in the living animal the corresponding pupil narrows more readily and completely than the control. By means of local applications and injections of nicotine it has been shown that there is a synapse of the constrictor fibres in the trigeminal sympathetic ganglion and of the dilatator fibres in the ciliary ganglion. There is thus shown to be in this fish a well-developed nervous mechanism for the control of the pupil, resembling that of mammals in general plan, but with the functions of the "antagonistic" nerves reversed. The pharmacological reactions of the m. sphincter iridis of *Uranoscopus* resemble those of the corresponding mammalian muscle.—*Author's summary.*

999. ARNAUDET, A., LÉON BINET, et H. CARDOT. Survie du centre respiratoire du poisson en fonction de la composition du liquide qui le perfuse. *Jour. Physiol. et Path. Gén.* 28(1): 50-55. 2 fig. 1930.—The activity of the respiratory centre of *Gobius lota* can be maintained from 3 to 5 hours by perfusion with appropriate neutral isotonic solutions. Urea up to 4.5% has a marked action in prolonging survival. The centre is extremely sensitive to variations in pH and osmotic pressure.—*W. R. Fearon.*

1000. ASHFORD, C. A., and E. G. HOLMES. Contributions to the study of brain metabolism. V. Rôle of phosphates in lactic acid production. *Biochem. Jour.* 23(2): 748-759. 1929.—Experiments on chopped rabbit brains in vitro indicate that the formation of lactic acid in brain tissue is principally from glucose, with which the presence of inorganic phosphates has little effect, and only in much smaller amount from glycogen, for which inorganic phosphates are necessary. Considerable lactic acid was liberated from glucose by chopped brain tissue in which phosphates had been completely removed by $CaCl_2$, and there was very slight increase in lactic acid formation when Na_2HPO_4 was added. When inorganic phosphates are precipitated by $CaCl_2$, there is complete inhibition of lactic acid formation from glycogen.—*H. R. Street.*

1001. BAJANDUROW, B. I. Zur Frage über die trophischen Funktionen des Kopfhirnes. Die Wirkung der Schädigung und der Entfernung des Kopfhirnes auf das Wachstum von Vögeln und Säugetieren. *Pflüger's Arch. Ges. Physiol.* 224(6): 779-786. 6 fig. 1930.—In the bird series chicks 2-4 wks. old and doves 4-6 wks. old (number not stated) and in the mammalian series 80 rabbits, 95 guinea-pigs and 25 rats were used. Complete removal of the cerebrum in young birds or bilateral injury in young mammals produced retardation of development, with fall in temperature, infantilism, change in gaseous metabolism (rise of respiratory quotient), decrease in N assimilation, disturbance of energy metabolism, and even complete arrest of development. Removal or injury of only one cerebral hemisphere, in either birds or mammals, had no effect on development. Partial removal or injury of both hemispheres checked growth. The injury to the somatic functions of the organism from removal or injury of the cerebrum indicates that there are in the prosencephalon mechanisms corresponding to the vegetative centers in the diencephalon.—*From author's summary (transl.).*

1002. BERGGREN, STURE, und ERIK MOBERG. Experimentelle Untersuchungen zum Problem des Schlafes. *Acta Psychiatr. et Neurol.* 4(1): 1-46. 11 pl. 1929.—In 24 experiments on cats, using solutions isotonic with the blood, the authors found that injections of small amounts of either $CaCl_2$ (0.26 to 0.62 mgm.) or KCl (0.44 to 0.55 mgm.) into the region of the infundibular and hypothalamic nuclei led to sleep. Control injections of Ringer solution into this region, and of $CaCl_2$ or KCl into other regions of the brain, were without effect.—*N. Kleitman.*

1003. BISHOP, G. H., and PETER HEINBECKER. Differentiation of axon types in visceral nerves by means of the potential record. *Amer. Jour. Physiol.* 94 (1): 170-200. 10 fig. 1930.—By means of the cathode ray oscillograph technique, 4 components of potential can be recognized in certain autonomic nerves. The vagus and the genital branch of the genito-crural contain all 4 components. Other nerves lack certain of these elements. The potentials are termed for convenience the A, B_1, B_2 and C components. Determinations have been made of the properties of the fiber groups which contribute to these potentials. The first 2 groups are similar to each other, the last 2 likewise resemble each other, the major differences in certain properties occurring between the 2nd and 3rd (B_1 and B_2) components. The properties which change more abruptly from the B_1 group to the B_2 are threshold, duration of axon potential response, chronaxie and absolutely refractory period, indicating a lower irritability and a slower activity and recovery in the last 2 groups, as compared to the first 2, in the ratio of at least 4 to 1. Histological cross sections of tested nerves lead to the inference that the first or A potential arises from large myelinated fibers of the type supplying skeletal muscle and peripheral afferent endings, i.e., somatic, motor and sensory. The B_1 potential arises from fibers of the type usually assigned to visceral afferent function, passing through autonomic nerves. The B_2 and C potentials arise from fibers which in certain nerves can be identified as autonomic efferents. Of these 2 groups the B_2 is inferred to contain the small thinly myelinated axons present in the autonomic system, the C the unmyelinated.—*Excerpts from authors' summary.*

1004. BLEICH, OTTO ERNST. Thanatose und Hypnose bei Coleopteren. Experimentelle Untersuchungen. *Zeitschr. Wiss. Biol. Abt. A., Zeitschr. Morphol. u. Ökol. Tiere* 10(1): 1-61. 21 fig. 1928.—The author treats 3 types of akinesia in Coleoptera, under the names thanatosis, catalepsy and mechanohypnosis. Thanatosis, or feigned death, is a reflex, hypertonic reaction which can be experimentally released or prolonged into paralysis by renewed stimulation. The reaction varies with the individual. As a rule the thoracic region must be stimulated, to break thanatosis, and the awakening is usually spontaneous. Chemical and optical stimuli do not interrupt thanatosis. Lowering the temp. lengthens and deepens the state, which has as its essential characteristic a fixed muscular tonus; the reflex irritability is lowered; each species assumes definite positions of the extremities and continues in this state for a characteristic period. Stimulation fatigue occurs only when the stimuli follow at short intervals, but reactivity is retained up to an hr. Reflex fatigue is overcome in many spp. by increasing the stimulus intensity and by changes in kind of stimulus. The thoracic ganglia in beetles play an important rôle in thanatosis. These studies were conducted with *Silpha obscura,* Broscus cephalotes,* Lucanus cervus,* Phyllopertha horticola,* Potosia cuprea,* Byrrhus pilula,* Corymbites aeneus,* Anobium striatum,* Blaps mortisaga,** and *Galeruca tanaceti** which are shown in the positions assumed in thanatosis, and detailed records are also given for many other spp., including some larvae. The studies in catalepsy were based on *Otiorrhynchus atroapterus.* Experimental catalepsy or mechanohypnosis was studied in *Cicindela hybrida,* Calosoma inquisitor,* Carabus granulatus,* Calathus fuscipes,* Poecilus lepidus,* P. punctatus,** etc., as tabulated.

1006. BRÜCKE, E. TH., und K. UMRATH. Über die Aktionsströme des Lymphherzens und seiner Nerven. *Pflüger's Arch. Ges. Physiol.* 224(5): 631-639. 6 fig. 1930. —Electrograms of tetanic action currents were obtained during each systole of the spontaneously beating lymph-heart of the frog, and from the 11th spinal nerve innervating the lymph-heart. In both cases the frequency of the higher peaks, formed by the coalescence of several single impulses, was about 20-30 per sec. The lymph-

heart is therefore not tonically innervated from the spinal cord in A. v. Tschermak's sense, but its spinal center works periodically, like the respiratory center.—*Authors' abstract (transl.).*

1007. BYKOW, K. M., und I. A. ALEXEJEW-BERKMANN. Die Ausbildung bedingter Reflexe auf Harnausscheidung. *Pflüger's Arch. Ges. Physiol.* 224(6): 710-721. 4 fig. 1930.—Experiments were carried out on 2 ♀ dogs, one with a single, the other with a double ureteral fistula. A conditioned reflex was built up by rectal injection of water in a certain room, accompanied by an organ peal of 4 min. The influence of the place and sound clearly increased diuresis, but the reflex was gradually lost when the unconditioned stimulus was not supplied. It was possible to inhibit renal conditioned reflexes, like alimentary conditioned reflexes, and thus to decrease water diuresis. It is concluded that renal activity is under the influence of the cerebral cortex.

1008. CARDOT, H., J. RÉGNIER, D. SANTENOISE, et VIDACOVITCH. Pneumogastrique et appareil thyroïdien. *Compt. Rend. Soc. Biol.* 99(19): 64-66. 1928.—After section of the pneumogastric followed by treatment with eserine, and the same treatment following removal of the superior cervical sympathetic ganglia, the authors conclude that it is the pneumogastric and not the sympathetic which conditions the cortical excitability of the thyroid.

1009. CATE, J. TEN. Beiträge zur Physiologie des Zentralnervensystems der Einsiedlerkrebse. *Arch. Néerland. Phys. Homme et Animaux III C.* 15(2): 242-252. 1930.—Shell-less hermit crabs find new shells mainly by touch, sight helping. Eupagurus bernardus performs a fixed chain of reflex activities in taking possession of a shell. Removing parts shows that touch is the main sense (sight helping) in this behavior and decreases in acuity from the antennae to the posterior legs. The behavior may be typically modified after loss of a receptor. Excisions demonstrate that the cerebral ganglion, assisted by the subesophageal, is dominant. The thoracic and abdominal ganglia subserve local reflexes. The subesophageal ganglion is a coördinating centre for locomotion and other complex actions, such as grasping, clambering, hiding, and death-feigning. It also reinforces the movements of the limbs and abdomen and inhibits the tonus of the abdominal muscles. The cerebral ganglion combines these actions into activities of a higher order, as when the crab finds a new shell.—*E. H. Craigie.*

1010. DIEHL, F. Über die Reizung sensibler Nerven nach Ausschaltung ihres peripheren Feldes. *Pflüger's Arch. Ges. Physiol.* 224(5): 678-686. 1930.—After anesthesia of the cutaneous field to which the sensation produced by stimulation of the cutaneous nerve is referred, the resulting sensation was referred to the margin of the anesthetized zone. The threshold of stimulus remained the same for equal current and condenser charge. Out of 35 experiments (number of subjects not stated) 25 were successful.—*From author's summary (transl.).*

1011. ECONOMO, C. von. Sleep as a problem of localization. *Jour. Nerv. & Ment. Dis.* 71(3): 249-259. 1 fig. 1930.—The author gives reasons for his belief that an area of grey matter limited posteriorly by the upper border of the oculomotor nucleus and extending forward under the lateral wall of the third ventricle towards the head of the caudate nucleus is of primary importance for the normal course of sleep. This "centre" is possibly activated by fatigue substances circulating in the blood stream, the results of its activation being (1) to inhibit the thalamus and cerebral cortex causing "cerebral sleep" and (2) to modify the action of the neighbouring sub-thalamic vegetative centres producing a changed metabolic state, which is normally present in the sleeping state and which he calls "body sleep." He mentions the experiments of Hess who has produced apparently normal sleep in cats by stimulation of the anterior region of the aqueduct and the posterior part of the wall of the third ventricle with very weak electric currents.—*E. A. Linell.*

1012. EUFINGER, H., und ILSE SEE. Das Verhalten des vegetativen Nervensystems in der Schwangerschaft auf Grund der Atropin-orthoclinostatischen Reaktion. *Arch. Gynaekol.* 140(2/3): 285-297. 5 fig. 1930.—Studies on 10 non-pregnant and 44 pregnant women indicate a heightened susceptibility to toxins during pregnancy. The Danielopolu or orthoclinostatic reaction to atropine shows no uniform tendency in respect to tonus of the vegetative nervous system in the 1st 9 lunar months of pregnancy. Along with marked lability goes a tendency to hypertonus in both systems. In the 10th month of pregnancy there is a marked tendency to increased tonus of the sympathetic. After confinement there is a delayed reaction to atropine.—*From authors' summary (transl.).*

1013. EWALD, G. Fortschritte und Wandlungen der psychiatrischen Lokalisationslehre. Erster Teil und zweiter Teil. *Scientia* 47(231-1): 21-30; (214-2): 101-110. 1930.—A historical review is given of the attitude in psychiatry towards the problem of localisation. This question is continually supported from the biological side, while it is mostly opposed on the psychological side. Since the recognition of the rôle of the brain in mental life, which was mainly due to the facts revealed by epidemic encephalitis,—the localisation theory in psychiatry, long repressed, has again gained ground. Further, both embryological and phylogenetic considerations point to the great significance of the thalamus in mental life. Intelligence can now be coordinated mainly with the cerebral cortex, sensation and impulse with the thalamus. The somatic basis of character may be perceived in the functional interaction between thalamus and cortex, both of which undergo the influence of the endocrine system and other agents of the organism as a whole. Temperament is best considered as the quantitative factor in somatic and psychological events, to which, on the bodily side, corresponds bio-tonus. The somatic controlling centres of this bio-tonus lie deeply in the brain-stem. It is shown that such a building-up of personality from the biological point of view agrees well with the psychological "personality typology" after Spranger. The modern theory of localisation is no longer a static-anatomical—but a dynamic-physiological theory of function. Naturally, it has its limitations, but it also has its justification.—*G. Ewald (transl. by J. M. Robson).*

1014. GEHUCHTEN, P. van. La pathologie du système pallido-strié. *Ann. Soc. Sci. Bruxelles Sér. C. Sci. Méd.* 48(3/4): 141-187. 8 pl. 1929.—A general review has been made of the physiology and pathology of the pallido-striate part of the central nervous system including its rôles and conduction pathways in the mechanisms of ordinary motion, of muscle tonus and of inhibition in involuntary movements (trembling, chorea, athetosis, spasm). The theories of physio-pathologic functions of the corpus striatum comprising the ideas of Ramsey, Hunt, Kleist, the Vogts, Foerster, Jacob and others are discussed. From the standpoint of pathology the various syndromes such as the Parkinson phenomenon in its several aspects and manifestations, Sydenham's chorea, Huntington's chorea, the syndrome of DeLuys' body, the athetoses, Little's disease, Wilson's disease and pseudosclerosis are described for the purpose of estimating the present status of investigation in this field. It is concluded that on the whole there is sufficient evidence to assume (1) that the globus pallidus is the center of primitive automatisms (2) that the pallido-striate system is the regulating center for muscular tonus and (3) that it is the regulating center for involuntary movements. More physiological, anatomical and pathological research is needed to elucidate the character of many of these mechanisms which are yet largely hypothetical.—*N. D. C. Lewis.*

1015. HINTNER, H. Über die mikroskopische Beobachtung des Dekrementes einer fortgeleiteten Erregungswelle an geschädigten Muskelfasern. *Pflüger's Arch. Ges. Physiol.* 224(5): 608-618. 5 fig. 1930.—Fresh preparations of the frogs' basihyoid membrane show, under microscopic observation of single fibers, during direct and indirect artificial stimulation, maximal tetanic twitchings.

A decrease of the excitation is to be distinctly noted as it travels along to the ends of severed fibers or fibers in injured tissues. The stronger the stimulus, the farther the wave of excitation travels along the fiber, generally with a gradual decrease, but now and then undergoing local diminution at spots which seem to offer obstacles to its passage. The view of Fischl and Kahn that the muscle fibers of the membrane do not follow the all-or-nothing law rests on fallacious observation. The apparent variation in intensity of motor response of muscle fibers to stimuli of varying strength is due to passive displacement and distortion increasing with increase of the stimulus.—*Author's summary (transl.).*

1016. **HOFF, HANS, und MICHAEL KAMIN. Reizversuche im linken Sulcus interparietalis beim Menschen.** *Zeitschr. Ges. Neurol. u. Psych.* 125(4/5): 693-699. 1930. —A war wound produced a skull deficiency over the sulcus interparietalis. Chilling this region caused a displacement of the visual field to the left, a darkening of the visual field, and finally inability to read or to distinguish colors, all being seen as brownish red. Faradization of the opposite side, and introduction of cold liquid into either ear likewise darkened the visual field. Another patient, with traumatic epilepsy from injury to a similar left cerebral region, responded to chilling of the lesion by displacement of the visual field to the right, darkening, similar confusion of colors, only green correctly identified, and by a feeling of embarrassment in speech; the speech was correct, but retarded. Warming the region caused no such speech disturbance, though there was a left displacement of objects seen and a yellow mist before the eyes. Cold fluid in the left ear produced the sensation of dark mist, but no loss of recognition of colors or of ability to read. Faradization of either side failed to elicit these phenomena. The authors suggest that these data point to a lateral distribution of the functions of this part of the brain, the right sulcus interparietalis preserving the sense of tactile unity of the body, while the left gives a sense of unity to the function of speech.

1017. **HOLMES, ERIC G. Carbohydrates of crab nerve.** *Biochem. Jour.* 23(6): 1182-1186. 1929.—Glycogen may constitute up to 20% of the total solids of *Maia* nerve. "Free carbohydrate" is present in the nerve of *Maia* and *Cancer.*—*E. B. Carmichael.*

1018. **JOHANNES, TH. Über die periphere nervöse Regulation des Wasserhaushalts.** *Pflüger's Arch. Ges. Physiol.* 224(6): 760-769. 3 fig. 1930.—The persons studied (number not stated) were subjected to stimulation of a cutaneous nerve by an alternating current of 2 frequencies while drinking either 1000 cc. water, or 150 cc. 10% NaCl. The threshold of sensitiveness rose during water drinking and fell after the salt intake. Corresponding changes in the curve were observed from other experiments with hypertonic solution, theobromin, etc.—*Author's summary (transl.).*

1019. **KATO, G., T. HAYASHI, M. NAKAYAMA, H. TAMURA, T. OTA, K. KANAI, and S. MATSUYAMA. The studies on the Wedensky effect.** *Japan. Med. World* 9(8): 245-282. 15 fig. 1930.—Narcotising-chamber-experiments were made to determine the point in the narcotised nerve at which the series of subnormal impulses coming from the upper normal part vanishes. The subnormal impulses are extinguished, not by decrement as supposed by Lucas, but at the beginning of the narcotised area, about 3 mm. inside of the upper wall of the narcotising chamber. The second (subnormal) impulse is extinguished on account of the heightened threshold in the relative refractory period due to the first (normal) impulse. This second impulse, although itself vanishing, leaves behind an "after-effect" which lasts long enough to inhibit the third and so on. Thus the Wedensky inhibition is produced.—*G. Kato.*

1020. **KOKAS, E. de. Relation entre les variations de la teneur du sang en calcium chez les lapins et les effets de l'excitation du nerf dépresseur.** *Jour. Physiol. et Path. Gén.* 28(2): 337-341. 6 fig. 1930.—By stimulating the depressor nerve in parathyroidectomised rabbits, before and after 2 cc. intravenous injections of 5% $CaCl_2$, it is shown that the excitability of the nerve depends on the Ca concentration of the blood.—*W. R. Fearon.*

1021. **KROLL, F. W. Elektrotonische Erregbarkeitsveränderungen des optischen Systems.** *Zeitschr. Ges. Neurol. u. Psych.* 125(1): 134-137. 1930.—Modified responses (anelectrotonus and catelectrotonus) were demonstrated with constant electric currents and adequate light stimuli.

1022. **MARTINO, G. Sul potere glicolitico della sostanza cerbrale.** *Boll. Soc. Ital. Biol. Sperim.* 5(2): 92-94. 1930.—Glycolysis by action of cerebral tissue was more efficient for the grey matter than for the white. Glycolysis took place at room temp. (17-22°) but the optimum was at 37-38°C. The rate was greatest in the first 7 hrs. The optimum concentration ratio between aqueous extract and glucose solution was 1: 10. Hydrocyanic acid inhibits glycolysis in concentrations below 0.001 N. Some cations increase, others inhibit glycolysis. All anions inhibit it, the phosphates excepted. Maximum glycolysis was observed at pH = 6.81.—*M. Comel.*

1023. **PASQUALINO, GUGLIELMO. Effetti del raffreddamento sull'eccitabilità muscolare diretta e indiretta negli animali omeotermi. [Effects of cooling on the direct and indirect muscular excitability in homoiotherms.]** *Arch. Fisiol.* 28(3): 443-451. 1930.—Cooling to about 11°C. the hind limb of dogs blocks the transmission of excitation from nerve to muscle, whereas at this temp. conductivity of the nerve, as well as direct muscular excitability, is present.—*M. Comel.*

1024. **PORTMANN, GEORGES. Action de la compression et de la ligature des gros vaisseaux du cou sur les réactions vestibulaires.** *Acta Oto-Laryngol.* 14(1/2): 303-321. 1930.—The study comprises 24 experiments on 4 dogs; they included examination of cardiac pulse, pupils, variation in color of mucosae, oculocardiac reflex and vestibular excitability before any intervention; injection of epinephrine, ergotin, eserin, pilocarpine, atropine, or bellafolin, with rotatory tests; ligature of the right common carotid or of the vertebral arteries; and repetition of the drug and rotation tests for comparison of the results with the former. The conclusions are: Rotatory tests repeatedly performed before and after ligature of the common carotid artery, before and after ligature of the vertebral arteries, before and after ligature and resection of the vertebral arteries, before any operation or after ligature of the left vertebral artery only, or of the 2 vertebral arteries, or both of these 2 arteries and the right common carotid together, produced no sensible modification of nystagmus.

1025. **RENQVIST, Y., und H. KOCH. Periodendauer und Nutzzeit des Wechselstromreizes bei sensiblen und motorischen Schwellen.** *Skand. Arch. Physiol.* 59(5/6): 279-294. 4 fig. 1930.—The action currents in sensory and motor nerves of the forearm were investigated by stimulating their endings with alternating currents of differing frequencies applied for different durations. The higher the frequency of the alternating current the lower the intensity of the action wave. This holds for an application of unlimited duration as well as for a limited one. With a frequency of 157.8 Hertz the action current intensity is at a minimum. It increases with lower frequencies. When the alternating current is applied for limited periods the curve of the intensities obtained in the nerves assumes a paraboloid form. Where the curve becomes approximately straight the term "most effective time" is defined by this point. This time is shorter with the lower frequencies and with 157.8 Hertz is equal to 3 sigma i.e., half the period for the frequency. This time is the same as that obtained when a condenser discharge is used and the same value is obtained when the alternating current is made unidirectional.—*Authors' summary (transl. by H. Woollard).*

1026. **ROSENBERG, HANS, und KAICHIRO KITAYAMA. Untersuchungen über Nervenaktionsströme. IV. Aktionsströme bei natürlicher Erregung (Strychninkrampf).** *Pflüger's Arch. Ges. Physiol.* 223(6): 712-732. 6 fig. 1930.—The authors studied action-currents in nerves and muscles under strychnine poisoning in animals. They

regard 400-600 per sec. as the maximal frequency for muscles and 200-300 per sec. as maximal for the nerves. The reflex latency is within the limit of 0.03 sec. The entire discharge complex of muscles is composed of a series of discharges which in their time relations correspond with those of the nerves. For example the duration of the wave varies from 0.07745 to 0.07125 sec. The intervals lasted from 0.01413 to 0.01361 sec. On the average the frequency consists of 11.3 series per sec. In view of these circumstances one must consider the frequency of the gross periods for nerve and muscle identical. By means of painful cutaneous stimuli of sensory nerve fibers of the sciatic, series of action-currents are demonstrable, the frequency of which series are equal to those of a motor bundle.—*A. P. Friedmann (transl. by J. M. Nielsen).*

1027. **SCHNEIDER, MAX. Ueber den Verlauf des Muskelaktionsstroms bei indirekter Zuckung und beim Eigenreflex.** *Zeitschr. Biol.* 89(6): 499-512. 8 fig. 1930.—N. tibialis and peroneus in man were stimulated by break shocks and the action current of the corresponding muscle groups recorded with string galvanometer and with oscillograph. The two resulting action currents which correspond to the reflexly elicited twitch and to the subsequent proprioceptive response were compared. The latter is more prolonged than the former. The magnitude of the prolongation does not surpass the value determined by Gasser and Erlanger for those nerve fibres concerned in the reflex response in question. It is concluded that the prolongation is solely conditioned by the different speeds of conduction in the various reflex paths employed; that the individual ganglion cells in the C.N.S. discharge synchronously if synchronously excited, but that the volley of impulses becomes more scattered the more peripherally the effector organ lies; and that the synapse plays no part in determining the course of the proprioceptive reflex. The observations of Altberger on the prolongation of the action current during extreme fatigue are confirmed; also the statement of Gasser, Erlanger and Bishop that the most rapidly conducting fibres are also the most excitable.—*M. Schneider (transl. by O. W. Tiegs).*

Jour.* 24(2): 400-401. 2 fig. 1930.—Both galactose and glucose, in Ringer plus phosphate buffer, prolong the period for which isolated mammalian nerves take up O at a steady rate.—*E. B. Carmichael.*

1029. **THORNVAL, ANDERS. Some experimental observations on the "otolith nystagmus" in pigeons.** [With French summary, p. 336-337.] *Acta Oto-Laryngol.* 14 (1/2): 333-337. 1930.—After plugging the semi-circular canals and then opening the bony canals between the right plugging and the distal extremity of the 2 vertical canals near the vestibule, one can call forth a movement of the head of the pigeon by increasing a little [blowing], whether slowly or rapidly, the pressure of air in the operative cavity. This motion has the character of a nystagmic movement with the slow phase forward and on the operated side, i.e., in the plane of the anterior vertical canal on the operated side; the rapid phase moves in the opposite direction [backward]. Reduction of the air pressure [sucking] in the operative cavity produces no effect, nor variations in the position of the head and body of the pigeon. After the extirpation of the posterior vertical canal with the ampulla, or of all the membranous canals with the ampullae, it seems that this nystagmic movement is the effect of an endolymphatic movement toward the utricle; one cannot explain it as an effect exercised on the ampullae.—*From author's summary (transl.).*

1030. **VEACH, H. O., L. L. SCHWARTZ, and M. WEINSTEIN. Studies on the innervation of smooth muscle V. On the relation of vagal gastric effects to Wedensky inhibition.** *Amer. Jour. Physiol.* 92(2): 453-456. 2 fig. 1930.—In recent experiments on 7 cats we have shown that McSwinney and Wadge (1928) were mistaken in their conclusion that vagal effects on cats' stomachs depend only upon degree of tonus of musculature preceding stimulation, and not on frequency or intensity of stimulation. Our experiments with luminal sodium anesthetic, as used by McSwinney and Wadge, show that on the contrary either a motor effect or an inhibitory reaction is produced depending upon frequency of stimulation, again affirming that vagal effects on the cat's stomach are of the nature of Wedensky inhibition. —*H. R. Street.*

1031. **WINTERSTEIN, HANS. Über Reizungs- und Erregungsstoffwechsel des Nervensystems.** *Pflüger's Arch. Ges. Physiol.* 224(6): 749-759. 2 fig. 1930.—The isolated nerves of frog's legs were used, prepared so that the directly stimulated section was in one respiration chamber while the remainder of the nerve, preserving its continuity, was sealed off in another. The described method showed that in the portion subject to direct electric excitation the gaseous metabolism rose markedly (as much as 80% in the case of the European frog), while in the portion of the nerve which merely conducted the disturbance no distinctly measurable increase in O consumption occurred. Artificial stimulation is thus seen to occasion 2 distinct categories of chemical processes: (1) the physiologic disturbance proceeding from the stimulated spot, and (2) the local process called forth by the electric current at the point of stimulation, which forms artificial products bearing no relation to the normal. This view is supported by observations of other authors. Unlike the gaseous metabolism is the increased sugar consumption produced in the isolated spinal cord of the frog by direct and reflex stimulation. This increase is due to the physiologic propagation of disturbances, and therefore can be only in small degree chargeable to oxidation processes.—*Author's summary (transl.).*

1032. **WRIGHT, SAMSON. Studies of reflex activity in involuntary nervous system. II. Action of ergotamine on vaso-motor reflexes.** *Jour. Physiol.* [*London*] 69(3): 331-347. 12 fig. 1930.—In the vagotomized cat under chloralose anesthesia, ergotamin in small doses prolongs the latent period of the depressor reflex, decreases the rate and extent of the fall of blood pressure and finally abolishes the reflex completely. When central vagus stimulation gives a mixed effect (initial rise followed by a fall or afterfall) ergotamin may convert the response into a pure rise. With larger doses the pressor reflexes are affected. The latent period is prolonged, the rate and extent of the rise of pressure are decreased and finally the reflex is completely abolished. At this stage there is no increased latency of the peripheral vascular mechanism and the vaso-motor "center" can respond strikingly to acute complete anemia. Evidence is offered that the effects described are mainly due to an action on the afferent side of the vaso-motor "center." The pressor sinus caroticus reflex is affected in the same way as artificially produced pressor reactions, and for the same reasons. It is suggested that the results obtained are opposed to the view of direct transmission of the excitation process through the vaso-motor "center." If Sherrington's conception of central excitatory and inhibitory states is adopted, the results may be accounted for by supposing that ergotamin prevents access of these states to the cells of the "center," possibly by modifying the condition of the surface membranes of the cells. —*Author's summary.*

1033. **ACKERMANN, RUDOLF.** Über den Einfluss des Rudertrainings auf die Lungenventilation, auf das Herz und das Blutbild. I. *Zeitschr. Klin. Med.* 106(3/4): 244-256. 1927.—Seventeen individuals with previous training and 19 training for the first time were studied. Training resulted in a greater increase in chest expansion in the 1st group than in the 2nd. Normal respiratory rate decreased. The resting pulse rate usually decreased but sometimes increased. Orthocardiac diagrams indicated an increase in the size of the heart. The effect on blood pressure was irregular.—*H. M. Krueger.*

1034. **ACKERMANN, RUDOLF, und FRIEDRICH LEBRECHT.** Über den Einfluss des Rudertrainings auf die Lungenventilation, auf das Herz und Blutbild. II. *Zeitschr. Klin. Med.* 107(5): 519-532. 1928.—Experienced and inexperienced rowers were compared before and after a period of training. The former group showed on the whole higher red cell counts before the training and showed in 82% of the subjects an increased hemoglobin value after the exercise. On the other hand 78% of the inexperienced rowers showed a decrease of hemoglobin after the training. In both groups of rowers 58-59% of the subjects showed increased red cell count after the training while the remainder showed a decrease. Among the experienced rowers there were more subjects with white counts greater than 8000. In both groups 66% of the subjects showed a decrease in white count after the training. Differential leucocyte counts were also made and the results are summarized. Significant correlations with the experience of the subject or the circulatory and respiratory changes could not be made.—*W. O. Fenn.*

1035. **AGAZZOTTI, A., e A. DE NIEDERHÄUSERN.** Modificazioni nella rana dell'attivitá lavorativa di un gastrocnemio per lesioni prodotte sull'arto del lato opposto. [Variations of working activity of gastrocnemius in frog following injury of the heterolateral limb.] *Boll. Soc. Ital. Biol. Sperim.* 5(5): 638-640. 1930.—The compression of the sciatic nerves due to ligation of one limb is followed by an increased working capacity in the gastrocnemius of the other limb of the frog. A chemical, not a reflex nervous factor, is responsible for this effect, because the increase of activity persisted after cutting the sciatic nerve, and was not present in the limb after ligation of the vessels. An increase of 20% in the glucose content was noted, to which is attributed the increase of working capacity.—*M. Comel.*

1036. **ALTENBURGER, H.** Über den reflektorischen und muskulären Anteil des Aktionsstrombildes bei Dehnung des quergestreiften Muskels. *Pflüger's Arch. Ges. Physiol.* 214(4): 524-531. 4 fig. 1926.—When the gastrocnemius of the frog is suddenly stretched, the sciatic nerve having previously been cut, there occur in the former action currents having a frequency of 60-100 per sec. which are dependent on the excitability of the muscle and are uninfluenced by curare and nerve degeneration. It is therefore assumed that they are caused by direct muscle stimulation. Muscle action currents arise also on passive stretching of human muscle. Their relation to the reflex component of the action current picture and their significance are investigated.—*Author's summary (transl. by O. W. Tiegs).*

1038. **BASLER, ADOLF.** Das Gehen und seine Veränderung durch verschiedene Umstände auf Grund experimenteller Untersuchungen. 274p. 114 fig. Gustav Fock: Leipzig; Verlag der Sun Yatsen-Universität: Canton, 1929.—The book is divided into 5 parts, each of which treats of some different phase of walking. Part I deals with the morphology of the locomotor apparatus and the changes in the lower limbs as steps are taken. The rôle of the toes receives particular emphasis. Part II treats of the dynamics of the leg musculature, joints and movements. Part III explains the rôle played by the body other than the legs during the process of walking. Parts IV and V consider the expenditure of energy and the different positions of the body, the balancing mechanism during swift running, climbing steep elevations and carrying heavy burdens. The last part is concerned strictly with the Chinese and describes the form of the feet, and the different types of walking by certain classes in China.—*C. S. Simkins.*

1039. **BASLER, ADOLF.** Experimentelle Untersuchungen über das Tragen mit Hilfe einer über die Schulter gelegten Stange. *Abhand. Med. Fak. Sun-Yatsen Univ. Canton* 1(1): 13-72. 33 fig. 1929.—In carrying loads the Chinese use 3 types of shoulder poles of bamboo or hardwood. Loads are suspended near the ends of the pole, and hang rather low so as to bring the center of gravity below that of the man's body without a load. The "physiological body size," or distance from the shoulder to the ground, is reduced. Methods are described for measuring such changes as those in "body size," position of the center of gravity and other physico-anatomical features. The lateral deviations of the center of gravity associated with carrying a load are greater than those of the man's body not loaded. The mean length of the pace in carrying a load is 1.115 m. With heavier loads the elastic spring of the rod has a lower frequency. The stronger the rod the higher will be its frequency. The bending of the rod during walking is such that the lowering of the center of gravity of the loads so produced is somewhat offset by the elevation of the center of gravity of the body at the same moment. As the pace frequency is timed to the frequency of bending of the rod, there is a quickened pace when a stout rod, necessary for a very heavy load, is used. At the same time a greater speed of walking may result, although with shorter steps. The elastic recoil of structures in the body to the impact of the load and the cushioning effect of the heel are considered, as well as the peculiarities of individual porters. The efficiency in carrying loads by this, as compared with other methods, is probably due to the slight deviations in center of gravity.—*H. S. Hopkins.*

1040. **BAYLISS, L. E., E. BOYLAND, and A. D. RITCHIE.** The adductor mechanism of Pecten. *Proc. Roy. Soc.* [*London*] *B* 106(745): 363-376. 1930.—The slow part of the adductor muscle of *P. magellanicus* on electrical stimulation gives a twitch which is about 100 times as slow as that of frog's skeletal muscle, owing to its high viscosity; large tensions may be developed. In *P. maximus* and *P. opercularis*, separation of the slow and quick muscles usually results in a "contracture" of the former, during which the viscosity is increased, although the tensions developed are relatively small. This is due to reflex excitation from the several nervous connections, and can be partly or completely abolished by direct faradisation of the muscle. In intact animals, it would appear that the muscle contracts tetanically for the most part. The quick muscle gives a rapid twitch on electrical stimulation; fusion of the twitches is not readily obtained, and fatigue is rapid.—*L. E. Bayliss.*

1041. **BERNSTEIN, NIK. Untersuchung der Körperbewegungen und Körperstellungen im Raum mittels Spiegelaufnahmen.** *Arbeitsphysiologie* 3(3): 179-206. 14 fig. 1930.—The moving body is simultaneously photographed directly and from a mirror placed at a definite angle to the optical axis of the camera. The mathematical derivation of the nomograms required for ascertaining the positions of points of the body during movement is given.—*T. M. Carpenter.*

1042. **BINET, L., G. BOURGUIGNON, P. CHAILLEY-BERT, J. GAUTRELET, L. LAPICQUE, J. LEFÈVRE, R. LERICHE, A. POLICARD, A. STROHL, et G. WEISS. Physiologie musculaire. Chaleur animale.** *Traité de Physiologie Normale et Pathologique.* Vol. 8. 742p. 176 illus. Masson et Cie: Paris, 1929. Pr. 110 Fr.—The book includes a general discussion by Lapicque of the physiology of muscle, the mechanics of contraction, muscle energetics, viscosity, excitation, and chronaxie and a chapter by Bourguignon describing the technique of making chronaxie determinations in man and other mammals and the results thereby obtained in normal and pathological conditions. In further chapters Weiss outlines the physical principles of mechanics and of calorimetry while Chailley-Bert discusses the various aspects of fatigue and outlines the mechanism of locomotion in man and quadrupeds as studied by moving pictures. Lefèvre has written 259 pages in a broad and fundamental way on animal heat and bioenergetics, including not only general considerations of energetics and thermodynamics but also the principles of biological calorimetry, basal metabolic rate, the nature of the foodstuffs burned, the regulation of body temperature, the distribution of temperature in the body and the effects of exposure to different temperatures. Further details of temperature regulation are given by Gautrelet writing on the defenses of the body against heat, the mechanism of heat loss and the physiology of fever and by Binet in a discussion of bodily reactions to cold. The book is concluded by shorter articles on bony tissues and ossification by Leriche and Policard and on electric organs and luminous tissues by Strohl. The book serves well as an advanced text or for reference. A considerable number of references to original papers are included.—*W. O. Fenn.*

[Action of urea on muscular imbibition and excitability.]** *Boll. Soc. Ital. Biol. Sperim.* 5(5): 641-643. 1930.—Muscular imbibition is greater for lower concentrations of urea, whereas it decreases for high concentrations. The electric excitability decreases quickly when the concentration of urea is raised.—*M. Comel.*

1049. **BÜTTNER, H. E., und B. HEIMBRECHT. Über den Einfluss des Sympathicus auf den Verkürzungsrückstand des Muskels.** *Pflüger's Arch. Ges. Physiol.* 221 (1/2): 93-103. 9 fig. 1929.—In the frog, after unilateral section of the sympathetic innervation of a leg, electrical stimulation of the same resulted in an increase in contraction remainder (Tiegel's contracture). Through investigations carried out on the isolated muscle it was found that the contraction remainder was distinctly increased after the addition of ammonia or ammonium-lactate in concentrations even as small as those found in sympathetic denervated muscles. The possibility of a relationship between contraction remainder and the NH_3 content of muscle is indicated.—*H. E. Büttner (transl. by H. S. Hopkins).*

1050. **CHARLET, HANS. Fortgesetzte Untersuchungen über den Einfluss des Sympathikus auf den Kontraktionsablauf ermüdeter Skelettmuskeln.** *Zeitschr. Biol.* 90(4): 299, 312. 7 fig. 1930.—For the sake of analyzing the influence of the sympathetic nerves on fatigued muscles a method was worked out to register the isometric twitch of a fatigued muscle photographically. Especial precautions were taken to interpolate the stimulation for the isometric contraction in an uninterrupted series of fatigue contractions without a longer pause than that between the individual fatigue contractions. Stimulating the sympathetic caused the rise of the isometric contraction of the fatigued muscle to become steeper, the time of ascent to be shortened and the height of contraction to be raised. But the whole duration of the contraction was not altered. The same phenomenon was found when analyzing a summed contraction by 2 stimulations in the ascending part of a contraction. The observed facts are an argument in favor of the view that stimulation of the sympathetic nerves causes an acceleration of the process of restitution.—*L. Asher.*

1051. **COLLE, J. Influence de l'excitant et du milieu extérieur sur les propriétés élastiques du muscle de grenouille. [The effect of the means of excitation and of the surrounding medium upon the elastic properties of frog muscle.]** *Arch. Internat. Physiol.* 31(2): 194-213. 5 fig. 1929.—Measurements were made of the tension developed by the sartorius muscle of the frog at different lengths. The length-tension diagrams so obtained were compared under different conditions. For purposes of comparison 3 constants were calculated from the curves for each condition. The constants were (1) the ratio of the area of the diagram W to the product Tl, or W/Tl. (2) the elasticity, E and (3) the maximum percentage shortening of the muscle under zero load. These constants change very little under the influence of temperature. Changes in the concentration of NaCl and the use of submaximal stimulation change the maximum work and the elasticity but leave the shortening unaffected, suggesting merely a change in the number of fibres ex-

cited. Changes in the concentration of $CaCl_2$ modify also the shortening and suggest a change in the nature of the elastic body. Lack of KCl has no effect.—*W. O. Fenn.*

1052. CROIX, PAUL MAGNE de la. La marche quadrupédale du chimpanzé et de l'homme. *Ann. Soc. Cient. Argentina* 110(6): 393-398. 3 fig. 1930.—A study of the gait of baboons and chimpanzees, compared with the movements of humans walking on all fours, shows the human type to be more advanced than that of the baboon but similar to that of the chimpanzee. This points to man's relationships with the latter rather than with the former.

1053. ERNST, E. Bemerkungen zu der Arbeit von Mond und Netter: "Ändert sich die Ionenpermeabilität des Muskels während seiner Tätigkeit?" *Pflüger's Arch. Ges. Physiol.* 226(2): 243. 1930.—A correction and a claim for priority.—*M. H. Jacobs.*

1054. ERNST, E., und L. SCHEFFER. Untersuchungen über Muskelkontraktion. VII. Mitteilung. Die Rolle des Kaliums in der Kontraktion. *Pflüger's Arch. Ges. Physiol.* 220(1/6): 655-671. 1928.—The K content of the frog's gastrocnemius is normally about 1.7% of the dry weight. When the muscle is perfused with Ringer solution for 5-6 hrs. it loses about 6% of its K content; perfusion with K free Ringer causes a loss of about 15%. Direct stimulation of the muscle brings about a K loss of 30-50%. The K loss can be explained by fatigue or by the lactic acid formation or by the increased permeability of the stimulated muscle. The Na content of the muscle increases to a greater extent than its Cl content and it is thus possible that there is a K-Na exchange in the stimulated muscle.—*E. Ernst (transl. by J. M. Robson).*

1055. FISCHER, ERNST. Die Wärmebildung des Skelettmuskels bei indirekter und direkter Reizung, sowie bei der Reflexzuckung. *Pflüger's Arch. Ges. Physiol.* 219(3/4): 514-553. 6 fig. 1928.—Indirect stimulation by maximal single shocks or short tetani produces the same tension as direct excitation. The initial heat liberated is however smaller with the indirect excitation. There is on the average a 6.5% decrease in the isometric quotient H/TL, which represents an increase in the efficiency of setting up tension. There is this smaller heat production in all 3 phases of heat liberation. The aerobic recovery heat is in both cases the same fraction of the initial heat. In doing a given amount of work the heat is less when indirect excitation is used than when direct is employed. With increased loading the heat produced increases to a maximum with both types of excitation. With further stretching the heat produced falls off at low temperatures but at higher temperatures stays at the maximum until the completely isometric loading is reached. In dying muscles and after incomplete curarization the isometric quotient is higher with indirect than direct excitation. Secretin not only impairs tension production but increases the isometric quotient of fresh muscle. Submaximal stimuli give lower quotients than maximal with both direct and indirect stimuli. In a tetanus a lower frequency of stimulation gives a larger tension-time area than a high frequency along with an equal or smaller heat production. By summation of stimuli at an interval of 5-15 σ an increased efficiency of tension production is obtained which may be increased by employing submaximal shocks. The increase in efficiency thus obtained helps to explain why reflex contractions show an isometric quotient 20-25% lower than by direct stimulation of muscle. There is an advantage to the economy of the organism in natural contraction consisting in tetanic summations of contraction.—*E. Fischer (transl. by M. B. Visscher).*

1056. FISCHER, ERNST. The oxygen-consumption of isolated muscles for isotonic and isometric twitches. *Amer. Jour. Physiol.* 96(1): 78-88. 1931.—By means of a differential-volumeter, the increased O consumption of a frog sartorius muscle after stimulation of the nerve by single induction shocks has been observed, for isometric twitches and for isotonic twitches of different loads. Two types of experiments were performed; in the 1st, the excess O consumption was determined for a series of 20-60 stimulations occurring in 1 or 2 min., while in the 2nd type the equilibrium consumption was measured for continuous stimulation with a frequency of 2-6 per min. Isotonic twitches with large loads, where little shortening occurs, have a higher O consumption than isometric twitches, while isotonic twitches with small loads and consequently large shortenings need less O than the isometric twitches. The value of 0.380 for the O consumption per gm. tension and unit of muscle length is in good agreement with the corresponding values of heat measurements. The maximal efficiency observed was 13.8%. From the experiments the conclusion is drawn that the energy liberated in a twitch depends on 2 factors, the length of the fibres during contraction and the work done (Fenn effect).—*Author's summary.*

1057. GARRY, R. C. The factors determining the most effective push or pull which can be exerted by a human being on a straight lever moving in a vertical plane. *Arbeitsphysiologie* 3(4): 330-346. 4 fig. 1930.—A study was made of the forces exerted by 12 males and 3 females in pushing and pulling a 30 inch lever that rotated in a vertical plane. The lever was attached to a 10-inch radius braked wheel connected by a braking belt to a spring balance. The machine was practically isometric and adjustments could be made to set the lever at various angles and to adjust the lever to different heights with respect to the subject. Body weight was the most important factor when a pulling effort was made at levels above the shoulder and when a pushing effort was made at levels below the shoulder. Whatever the magnitude, the effort made by the body was most effective as regards the lever only when applied at right angles to the lever.—*T. M. Carpenter.*

1058. GELFAN, S., and R. W. GERARD. Studies of single muscle fibres. II. A further analysis of the grading mechanism. *Amer. Jour. Physiol.* 95(2): 412-416. 1930.—The response of a single muscle fibre to induction shocks applied by microelectrodes has been studied. As stimulus strength is increased the length of fibre responding and the size of the response similarly increases. This parallelism continues longest when the electrodes are finest and most closely applied to the fibre but even then, after the contraction has spread a distance of about 1 mm., an all-or-nothing response of the entire fibre breaks through with further increase of stimulus intensity. This is in accord with an interpretation of the graded responses that more accurately defines the all-or-nothing phenomenon and which is developed in the text.—*Authors' summary.*

1059. GELFAN, SAMUEL. Studies of single muscle fibres. III. Further evidence of graded responses in single fibres. *Amer. Jour. Physiol.* 96(1): 16-20. 1931.—The intact frog's sartorius gives graded contractions of single fibres in response to graded intensities of stimuli. To evoke submaximal responses in a single fibre that is fresh and uninjured, the microelectrodes must not exceed a certain size, so that the localized stimulation of the single fibre is not too diffuse. Since the response is not independent of the stimulus intensity, upon direct microstimulation, the all-or-none law for the muscle, to that extent, is not valid.—*Author's summary.*

1060. GEMMILL, C., W. BOOTH, J. DETRICK, and H. SCHIEBEL. Muscular training. II. The effect of training on the recovery period following severe muscular exercise. *Amer. Jour. Physiol.* 96(2): 265-277. 1931.—A study was made of the effect on the metabolism, ventilation, respiratory and pulse rates and blood pressure, during the recovery period following severe exercise on a treadmill in 2 subjects before and during a course of training to running. The metabolism, blood pressure, pulse rates and gross and net R.Q. for the recovery period to the standard work did not change during the training. The total ventilation of one subject (W.B.) showed a decrease in amount. For a 2nd subject (C.G.) one result before training was as low as any of the results during training. There was an increased

rate of return to normal in both subjects. The number of respirations in W.B. during the earlier portion of the recovery was less during training than before. In C.G. the rate of return to normal was increased by training. The course of the recovery period can be expressed in terms of the logistic function.—*Authors' summary.*

1061. **GERTZ, HANS. The working power in the 100 metres' race.** *Skand. Arch. Physiol.* 55(1/5): 131-143. 4 fig. 1929.—The working power is deduced from the rate with which the velocity increases during the race. Data were obtained from 3 cases in the literature. The speed attains a maximum at the end of the 3rd second and then decreases. During the period of acceleration for a runner of 75 kgm. the working power is 3 to 5 horse power. At the point of maximum speed it is 8 to 12 horse power, after which it decreases to 6 to 8 horse power.—*W. O. Fenn.*

1062. **GHIRARDI, G. E. La propagazione dell'eccitamento causato da veratrina e nicotina nel sartorio di bufo. [The propagation of the excitation from veratrine and nicotine in the muscle.]** *Arch. di Sci. Biol.* 13(1/2): 185-205. 9 fig. 1929.—Experiments on the toad sartorius (two-portions method). Nicotine and veratrine, applied by dropping in small doses on one part of the muscle, caused an excitation propagated to the other portion. Large doses evoke contracture which is propagated from the affected to the intact portion, wholly with nicotine, partially in the case of veratrine. Thus on the plateau of the veratrine contracture some spontaneous contractions appear as Bottazzi has already demonstrated. Veratrine diffuses so slowly that its presence in the untreated portion can be recognised only when the treated portion has lost all capacity for response. Contracture and spontaneous contractions are two well distinguished phenomena; the first is due to the activity of sarcoplasm, the others to the myofibrils. The results of the author support the dualistic theory of muscular activity, as set forth by Bottazzi.—*A. Jappelli.*

1063. **GOLDNER, MARTIN, HERBERT HERXHEIMER, und RICHARD KOST. Veränderungen im Komplementgehalt des Blutes nach maximaler Muskelarbeit.** *Zeitschr. Klin. Med.* 113(5/6): 553-559. 4 fig. 1930. —The study was undertaken to seek a criterion for "overtraining." The form of test effort chosen was a 1000-m. run, singly and repeated at 24-hr. intervals. The 5 subjects included 2 trained runners, 2 athletes without track training, and 1 person without athletic training. Complement was lowered, as compared with resting complement content, immediately after the effort and for 48 hrs. thereafter, in all the subjects without regard to training condition or previous experience.

1064. **HELLER, ROBERT. Permeabilität und Ermüdung. III. Die Bedeutung der Stromflusszeit für den Verlauf der Ermüdungskurve und den Wendungseffekt.** *Pflüger's Arch. Ges. Physiol.* 225(2/3): 194-229. 14 fig. 1930.—An arrangement is described for stimulation with saturation currents and with rhythmic rectangular current impulses of different durations. Continuous contractions can be obtained which are not due to tetany, since when impulses of a longer duration are used twitches are seen. A comparison of the action of rest with that of reversing the stimulating current, with respect to the restoration of the irritability of the muscle, shows that a true reversal effect can be obtained with submaximal stimuli. A muscle is more quickly fatigued by electric impulses of relatively long duration and vice versa. The recovery elicited by reversing the current, i.e., the reversal effect, is less with shorter durations. Accordingly the course and shape of the fatigue curve is dependent upon the duration and the direction of current flow, condition of muscles, the kind of muscle, the kind of stimulation (in air or liquid) and on the length of the experiment. Its fall can be abrupt or gradual. These facts are explained by the assumption that the current causes local fatigue at the cathode, and local recovery at the anode due to the permeability changes in the cell surfaces.—*J. M. Ort.*

1065. **HERZOG, FRANZ. Über die myostatische Innervation antagonistischer Muskeln.** *Deutsche Zeitschr. Nervenheilk.* 96(1/3): 23-42. 1927.—When a healthy finger is released from a flexing or extending weight it first moves in a direction opposite to the pull, then fluctuates a little and comes to rest. Arguments are presented to prove that these movements are due to the physical properties of the tissues and their quick cessation to the myostatic innervation. Tracings of this kind of behavior are given for healthy and diseased subjects. The author's most important conclusion from the analysis of the tracings is that there is a quantitative difference between the effects of the cerebellum and the corpus striatum on muscles of different functions. The former is concerned chiefly with flexors, the latter with extensors.—*H. Woollard.*

1066. **HILL, A. V., and P. S. KUPALOV. The vapour pressure of muscle.** *Proc. Roy. Soc.* [*London*] *B* 106(746): 445-477. 1930.—The increment previously reported in the rate of heat production of a muscle at rest, following stimulation in N, is due to a decrease of vapor pressure resulting from anaerobic activity. It is caused by the slow condensation of water, on its surface, from the Ringer's solution with which the muscle was previously in equilibrium. This change of vapor pressure is directly proportional to the change of osmotic pressure (or of molecular concentration) which causes it. The change of osmotic pressure set up in the fluids of a muscle stimulated anaerobically is nearly proportional to the amount of energy set free. In a frog's sartorius completely fatigued (lactic acid production 0.3%) the increase of osmotic pressure is the same as would be caused by the addition of 0.35% of NaCl to Ringer's solution. The increase of osmotic pressure in the fluids of a stimulated muscle is about 2.8 times as great as would be exerted by the lactate ions produced, if dissolved in the "free" water of the muscle. It is 1.8 times as great as would correspond to the lactate ions together with the creatine liberated by the breakdown of phosphagen. It is appreciably greater than can be accounted for by all the chemical changes at present known, or suspected, to occur in stimulated muscle. When an acid (carbonic) is added artificially to muscle, the increase of osmotic pressure corresponds approximately to the anions formed. The depression of vapor pressure of frog's blood has been measured. Its mean value is that of a 0.725% solution of NaCl. The osmotic pressure of frogs' resting muscles, assumed to be isotonic with blood, can be almost exactly accounted for by assuming the known soluble constituents of muscle to be dissolved in its "free" water. The osmotic pressure of fatigued muscles cannot be so accounted for. Presumably, therefore, some hitherto unrecognised substances are liberated as the result of activity.—*A. V. Hill.*

1067. **KAGAN, E. M., und A. S. BARSTSCHEWSKY. Physiologisch-optimale Arbeitsbedingungen beim Gewichtheben.** *Arbeitsphysiologie* 3(1/2): 120-167. 3 fig. 1930.—The object of the investigation was to determine the optimum conditions with regard to weight, rate of lifting, and height of lift as indicated by the determination of heat output and efficiency during work. Two subjects were used, F, 184 cm., 83.9 kgm., and L, 158 cm., 60.1 kgm. The gaseous exchange was measured by the Benedict apparatus during 5 min. periods of work and 15.4 min. of recovery. The weights were 5, 10, 16, 20, and 26.5 kgm. The lifts varied from 0.5 to 1.5 m. in rise and from the ground to one meter at the start. Four rates were used: 4, 8, 12 and 16 per min. Two hundred and thirty-two combinations out of 240 possible were studied in 2,078 experiments. The most advantageous condition with subject F was the lifting of 20 kgm. from 0.5 at the start to 1.5 m. with the rate of 8 lifts per min. This required an energy expenditure of 20.49 calories per kilogrammeter with an efficiency of 9.5%. For L the optimum condition was 16 kgm. 12 times per min. with a lift from 0.5 m. to 1.5 m., which required an energy expenditure of 22.7 calories per kilogrammeter with an efficiency of 10.3%. A discussion is given of the various factors influencing efficiency, par-

ticularly of the elements of energy expenditure in raising the body itself and in maintenance of body position and balance, with reference to the increase in the groups of muscles involved as the work progressed in severity. The two individuals were of such different build that these various elements did not play the same rôle under all conditions with each of them.—*T. M. Carpenter.*

1068. KANN, SUSANNE. Permeabilität und Ermüdung. V. Ermüdbarkeit und Wendungseffekt bei Reizung mit Induktionsströmen. *Pflüger's Arch. Ges. Physiol.* 225(2/3): 265-297. 9 fig. 1930.—After fatigue of the isolated frog gastrocnemius with a tetanizing current a typical reversal effect can be observed, i.e., recovery can be obtained by reversing the current. The muscle, being polarizable, prevents the "make" in the induction primary from causing much flow in the stimulating circuit. Hence stimulation with only the "break" impulses gives the same fatigue curve as with both make and break acting simultaneously. The value of the reversal effect in both cases decreases with increasing strength of stimuli. Fatigue appears quicker when only make stimuli are used, and therefore the reversal effect is greater for all strengths of stimuli and for both current directions after stimulation by make than by break impulses. This agrees with Heller's previous work on the effect of the time interval of current passage. Fatigue from very short lasting break stimuli is recovered from faster by rest than by an equally long lasting reversal current at the start of an experiment but about equally at the end. For fatigue from make impulses the reversal effect is more powerful than rest towards the end. Recovery from fatigue from rhythmic condenser discharges is more rapid by the reversal effect when the time interval of each current impulse is comparatively long, but if this time interval be made rather short, rest is about equally effective. These phenomena are explained by the assumption that the membrane processes at the cathode are two:—that due directly to the stimulating current and that due to the wave of excitation. Only the latter is also the same at the anode, where the direct effect of the current is antagonistic. With short lasting currents therefore the reversal effect is small and dependent on the strength of the impulse because with this, the intensity of the excitation wave itself changes.—*J. M. Ort.*

1069. KATZENSTEIN, WALTER F. Über die Veränderung der Elastizität des Bindegewebes durch die Ermüdung. *Zeitschr. Ges. Exp. Med.* 74(5/6): 575-585. 1930.—Experiments were carried out to see if fatigue changes the elasticity of connective tissues. This was shown on living animals by excluding all other influences. By means of a cannula the knee joint was punctured and the capacity of the joint was determined by injecting water under uniform pressure. 4 preparatory experiments showed equal capacities on the right and left sides. In 8 regular experiments involving flexion and extension of one of the knees 3000 times, an increased capacity was found on the fatigued side, showing that the elasticity was decreased. Control experiments on 4 dogs fatigued by running on treadmills gave the same results. The size of the joints was shown graphically. The elasticity of connective tissue depends therefore upon the functional ability of the tissue, and is not constant.—*Author's summary (transl. by M. Seham).*

1070. KISSELEFF, M. Die Reaktion des M. quadriceps bei gleichzeitiger Beugung der beiden hinteren Extremitäten der decerebrierten Katze. *Pflüger's Arch. Ges. Physiol.* 225(2/3): 357-363. 2 fig. 1930.—The simultaneous passive extension of both knee-extensors in decerebrate animals produces a greater muscular tension and a greater action current than does extension on only one side. The biological significance of this reaction in the act of standing is discussed.—*Author's summary (transl. by H. R. Street).*

1071. LINDHARD, J., and JENS P. MÖLLER. On the origin of the initial heat in muscular contraction. *Kgl. Danske Videnskab. Selskab. Biol. Meddel.* 8(8): (1-21). 1930.—The authors find theoretical objection to explaining the initial outburst of heat in a muscular contraction as due to the development of tension. It is shown that the sartorius muscle changes its shape even in an isometric contraction. This is due to the tapering shape of the fibres which permits the large end to shorten slightly while the small end is stretched. This change in shape involves a loss of potential energy and hence a production of heat which is believed to be the explanation of the initial outburst of heat. A further loss of potential energy would occur with further shortening and the accompanying heat production is believed to explain the increased excess heat produced when a muscle does work, thus disposing of "the only remnant of the theories of Fenn."—*W. O. Fenn.*

1072. LUNDSGAARD, EINAR. Inwiefern beeinflussen Eiweissstoffe und deren normale Abbauprodukte den Zuckergehalt des Blutes? *Biochem. Zeitschr.* 217(1/3): 125-146. 1930.—The amino-acid hyperglycemia of Pollak and Nord is demonstrated to be a toxic phenomenon only to be produced by parenteral administration of amino acids in very large amounts. Oral administration of amino-acids to rabbits, amino-acids and meat to dogs and meat to humans in large quantities has no influence on the sugar content of the blood.—*E. Lundsgaard.*

1073. LUNDSGAARD, EINAR. Über die Ursache der Aminosäurehyperglykämie. *Biochem. Zeitschr.* 217(1/3): 147-161. 1930.—A hyperglycemia can be produced by NH_4 salts in doses which raise the content of ammonia in the blood to 0.65 mgm. %. When a hyperglycemia is produced by amino-acids the content of ammonia in the blood is somewhat raised but by no means to this level. The amino-acid hyperglycemia seems to run parallel to the amino-acid content of the blood and is not identical with the hyperglycemia produced by NH_4 salts.—*E. Lundsgaard.*

1074. LUNDSGAARD, EINAR. Untersuchungen über Muskelkontraktionen ohne Milchsäurebildung. *Biochem. Zeitschr.* 217(1/3): 162-177. 1 fig. 1930.—Muscles of frogs poisoned with iodo-acetic acid are able to perform a prolonged series of contractions without any formation of lactic acid. When exhausted they become rigid. In muscles working without formation of lactic acid a breakdown of creatine-phosphoric acid much more rapid than in normal muscles takes place. It is suggested that the breaking down of c-ph acid produces the energy for the contractions of the poisoned muscles. Calculations of the energy-output from the chemical changes in normal and poisoned muscles support this view.—*E. Lundsgaard.*

1075. MORAN, T. The frozen state in mammalian muscle. *Proc. Roy. Soc. [London] B* 107(749): 182-187. 1930.—When mammalian muscle is frozen there is a breakdown in the structure of the muscle which is shown by the free fluid which drains away on thawing. Recent work on the freezing of living tissues has shown that the effects of freezing and desiccation are identical. The present work was undertaken to fix the amounts of water frozen out from muscle at different temp. At $-20°$ C. 94-98% of the water in the muscle is present as ice, indicating that the amount of "bound" water is not greater than 6% of the total water in the muscle.—*T. Moran.*

1076. MÜLLER, E. A. Der Einfluss der Kontraktionsgeschwindigkeit auf den Energieverbrauch bei einer statischen Arbeit. *Arbeitsphysiologie* 3(4): 298-308. 6 fig. 1930.—The experiments were made on the flexors of the elbow contracting isometrically against a U shaped steel spring the movements of which were recorded. The energy expenditure of the subject was measured by the Benedict respiration apparatus. By varying the duration of maintenance of tension from 0 to 14 sec., it was found that the energy expenditure per sec. per Kgm. of tension was 2.6 gram calories when 20 kilograms tension was maintained. It was also found that the energy expended in developing the desired tension varied with the duration of the rise of tension when the time varied from 0.3 to 1.5 sec., but at faster rates, there was an increase in energy expenditure. For the conditions of the experiment, the energy expenditure per unit of time in the rise of tension was equal to ½ the energy pro-

duction during the maintenance of the same tension. The optimal time of rise of tension is proportional to the tension attained. The shorter the load arm is with a definite external load, the smaller is the optimal time for rise of tension. The energy expenditure in the rise of tension in the optimal time increases faster than the increase in the distance of the load from the elbow.—*T. M. Carpenter.*

1077. **NISHIMURA, KIKUGORO.** Lactic acid in the muscle of the octopus. *Acta Scholae Med. Univ. Imp. Kioto* 12(1): 83-85. 1929.—Evidence is presented to show that the autolytic production of lactic and phosphoric acids in *Octopus* muscle incubated for 72 hrs. at 37° C. is increased in the presence of carbohydrate (glucose) or $CaCl_2$. Optimum concentrations appear to be 2% of glucose or 0.1% of $CaCl_2$. Lactic acid was isolated by Matsumoto's method and estimated gravimetrically. Neumann's method was used in the estimation of phosphoric acid.—*P. W. Smith.*

1078. **OSTERHOUT, W. J. V., and E. S. HARRIS.** Bioelectrical aspects of the all or none law. *Proc. Soc. Exp. Biol. & Med.* 26(9): 838-842. 1929.—Muscle and nerve fibers respond to a stimulus as though they were in electrical series, the inactive fibres acting as shunts. A formula for determining the potential difference of the stimulated muscle is suggested. Experiments with *Nitella* in which strands of cells were bound together to simulate muscle but permit study of separate strands uphold this view.—*M. B. Garnett.*

1079. **PRYDE, JOHN, and EDWARD THOMAS WATERS.** The nature of the sugar residue in the hexosemonophosphoric acid of muscle. *Biochem. Jour.* 23(3): 573-582. 1929.—The hexosephosphoric acid of normal muscle-press juice from rabbit, goat and donkey is a monophosphoric acid. The diphosphoric acid is only obtained when the fermentative resynthesis using NaF is employed. Evidence on the nature of the sugar residue in hexosemonophosphoric acid was obtained by oxidation to the corresponding hexonic acid by the use of bromine, and the subsequent removal of the phosphoric acid group with 10% H_2SO_4 in a sealed tube at 100°. The pure hexonic acid showed changes in specific rotation when heated similar to those obtained with gluconic acid when similarly treated, from which it is concluded that the aldose of hexosemonophosphoric acid is d-glucose. The Willstätter-Schudel oxidation indicates the presence of 90% aldose in the hexose of the acid, and since after the oxidation the solution still reduced Fehling's solution the presence of a ketose accounting for the remainder of about 10% is indicated.—*McKeen Cattell.*

1080. **RIABUSCHINSKY, N. P.** Einfluss der Darreichung von Phosphaten per os auf die Arbeitsfähigkeit und den Gaswechsel. [The effect of oral administration of phosphate on working capacity and gaseous metabolism.] *Zeitschr. Ges. Exp. Med.* 72(1/2): 20-31. 4 fig. 1930.—The oral administration of supplementary amounts of phosphates to 4 experimental persons raised the capacity for effort in varying degree. The experiments furnished no evidence of a specific lessening of the need for O through the action of phosphate during work.—*From author's summary (transl.).*

1081. **SAMOJLOFF, A.** Über die reflektorische Plastizität des Muskels beim decerebrierten Tier. *Pflüger's Arch. Ges. Physiol.* 225(5/6): 782-789. 3 fig. 1930.—It is shown that the appearance of reflex plasticity in the M. quadriceps of decerebrate cats is dependent in the highest degree upon the condition of the same muscle on the other side. If the M. quadriceps of one leg is fixed in a condition of marked extension, then in the M. quadriceps on the other side no plasticity at all may be produced: if, on the other hand, one M. quadriceps is kept in a condition of strong passive shortening then in the other muscle plasticity appears at once. It is shown that each degree of flexion of one knee corresponds to a definite degree of flexion of the other. But there is, ceteris paribus, a certain angle of flexion which is the same for both extremities.—*Author's summary (transl. by H. R. Street).*

1082. **SCHEMINZKY, FERDINAND, und FRIEDRIKE SCHEMINZKY.** Permeabilität und Ermüdung. II. Ist der Wendungseffekt durch die Reizung neuer Fasern oder durch Grenzflächenänderungen schon erregter Fasern bedingt? *Pflüger's Arch. Ges. Physiol.* 225(2/3): 145-193. 14 fig. 1930.—After fatigue of frog muscle had been produced by a series of rhythmic unidirectional electric currents, recovery could be obtained by a reversal of the current direction in half the time required for recovery by rest alone. If after fatigue has been so produced, the muscle be further stimulated by stronger shocks, the restoration by current reversal may be more than 10 times as speedy as that from rest. The data show that the reversal effect can occur with the stimuli either maximal or submaximal. It is concluded that fatigue is a local effect at the cathode due to a permeability increase. The reversal effect is then the reversal of this increase of permeability when the cathode becomes the anode, i.e., a physical chemical change at surfaces. The significance of the swelling and shrinking due to the water transport of electro-osmosis is also discussed. The fatigue due to a definite current direction, kind of stimuli, current strength and frequency of stimulation is defined as the "relative fatigue." The amount of the total available energy of the muscle that has been used up is called the "absolute fatigue."—*J. M. Ort.*

1083. **SCHUSTER, M.** Biochemisches Kriterium des Arbeitswertes und der konstitutionellen Eigenschaften bei Pferden. 2. Teil: Quantitatives Verhältnis zwischen Milchsäure und anorganischer Phosphorsäure im Zusammenhang mit dem Arbeitswert und der Konstitution. *Zeitschr. Zücht. Reihe B. Tierzücht. u. Züchtungsbiol.* 18(3): 423-432. 1930.—Blood tests taken after fast running offer the best method of judging the working capacity of the organism. Such tests show: (1) there is no correlation between lactic acid and P_2O_5 variation; (2) the amount of increase in lactic acid concentration depends upon speed; (3) P_2O_5 increases after work except in horses in group III, in which it decreases, but is not influenced by the intensity of the work and shows no correlation with the other components.—*Author's summary (transl. by M. E. Collett).*

1084. **SMITH, E. C.** The heat of rigor of mammalian muscle. *Proc. Roy. Soc. [London] B* 107(750): 214-222. 1930.—The heat evolved by normal rabbit's muscle during the process of stiffening in rigor mortis can be attributed entirely to the breakdown of glycogen to lactic acid. In starved animals there is evidence that other reactions contribute to the evolution of heat.—*E. C. Smith.*

1085. **SOLUN, A. S.** Biochemisches Kriterium des Arbeitswertes und der konstitutionellen Eigenschaften bei Pferden. 1 Teil: Quantitative Verhältnisse zwischen Milchsäure, Blutzucker und Alkalireserve im Blute im Zusammenhang mit der Arbeitsleistung beim Pferde. *Zeitschr. Zücht. Reihe B. Tierzücht. u. Züchtungsbiol.* 18(3): 398-422. 1930.—The lactic acid, blood sugar and alkaline reserve vary considerably even in the resting state in horses. It is therefore difficult to ascertain the exact effect of activity, although the differences become clearer with severe exercise. In rapid work lactic acid and blood sugar increase and alkaline reserve decreases: the change is most evident in the case of blood sugar. The best horses show the least change, and with training the amount of change is further diminished.—*Author's conclusions (transl. by M. E. Collett).*

1086. **SNAPPER, I., und A. GRÜNBAUM.** Über den Abbau von Diacetsäure und β-Oxybuttersäure in den Muskeln. *Biochem. Zeitschr.* 201(4/6): 464-472. 1928.—Even after removal of both kidneys diacetic and β-oxybutyric acids disappear rapidly from the blood after intravenous injection. Similarly in perfusions of the hind legs of dogs 45-75% of the added β-oxybutyric acid is broken down without appearing as diacetic acid. Diacetic acid added under similar conditions is broken down (80%) or appears in the tissue as β-oxybutyric acid (20%). In perfusions of calves' tongues 13-40% of the added β-oxybutyric acid is broken down while 29-67% of the added diacetic acid is found in the tissues as β-oxybutyric acid.—*W. O. Fenn.*

1087. UFLAND, I. M. Zur Frage der Untersuchung der Muskelchronaxie beim Menschen. *Pflüger's Arch. Ges. Physiol.* 226(1): 47-57. 1 fig. 1930.—Using on over 800 subjects a technique similar to that employed by Bourguignon, the author confirms Bourguignon's value for the biceps brachii (0.08-0.166), obtains slightly higher figures than Bourguignon for the extensor digitorum communis, for which he confirms Lewy's result (0.4-0.86) for males, which he raises to 1.6 as the upper normal limit for females. An antagonist, flexor digit. comm. prof., varied from values 1.1 to 5 times those of the extensor. Values for women are found to average higher than those for men, those for the right hand often higher than those for the left among both right and left handed subjects. Variations in chronaxie are far smaller than those of rheobase.—*G. P. McCouch.*

1088. WACHHOLDER, KURT, und JOACHIM Freiherr von LEDEBUR. Untersuchungen über "tonische" und "nichttonische" Wirbeltiermuskeln. I. Die Umklammerungshaltung des Frosches und die Schutzhaltung der Schildkröte; ihre spezifische Nachahmung durch muskuläre Acetylcholinwirkung. *Pflüger's Arch. Ges. Physiol.* 225(5/6): 627-642. 1 fig. 1930.—The clasping posture of a frog and the defence posture of a tortoise (drawing the head, extremities and tail back under the shell) are described in detail. Both of them can be imitated in a quite normal manner by the purely muscular action of acetylcholin. This is based upon the fact that acetylcholin has specific selective action in causing a strong protracted contraction only in the clasping muscles or the retractors but not at all or at least considerably less in their antagonists. The same difference exists also for other stimuli, especially for a mechanical stimulus. The finding first brought out by Sommerkamp that the skeletal muscles of a frog in their reaction to acetylcholin can be noticeably differentiated as "tonic" and "non-tonic" is therefore confirmed and at the same time extended to the tortoise. Above all it is shown that the distribution of the "tonic" and "non-tonic" muscles is in no case accidental but highly serviceable in promoting the security of the above mentioned biologically important postures of long duration.—*Authors' summary (transl. by P. S. Kupalov).*

1089. WACHHOLDER, KURT. Untersuchungen über "tonische" und "nicht, tonische" Wirbeltiermuskeln. II. Acetylcholin- und Tiegelsche Contractur in ihren Beziehungen zueinander und zur tetanischen Kontraktionsform. Die Plastizität der beiden Muskelarten. *Pflüger's Arch. Ges. Physiol.* 226(2): 255-273. 12 fig. 1930.—Following Sommerkamp's nomenclature, those muscles or parts of muscles which react to acetylcholin with a strong, long sustained contracture are classed as "tonic." In such muscles Tiegel's contracture is clearly elicited. Only exceptionally is it found in muscles which do not develop contracture with acetylcholin. Both types of contracture are prevented or reduced by atropin and by weak stimulation. Tiegel's contracture is shown to be too great in amplitude to be explained as a local cathodal contraction. Isotonic submaximal twitches and tetani may be increased in amplitude by acetylcholin but maximal tetani are not. Since tetanus and contracture tend to fatigue synchronously, the author inclines to the view that they involve identical contractile elements. He considers "tonic" muscles to be more plastic than other muscles.—*G. P. McCouch.*

1090. WACHHOLDER, KURT. Untersuchungen über "tonische" und "nicht tonische" Wirbeltiermuskeln. III. Verschiedenes Verhalten bei ermüdender Reizung. *Pflüger's Arch. Ges. Physiol.* 226(2): 274-291. 10 fig. 1930.—Employing as a "tonic" muscle the coraco-radialis and as "non-tonic" muscles the deltoid and triceps of the frog, the "tonic" muscle is found more resistant than the "non-tonic" muscle to fatigue, induced by repeated submaximal or maximal induction shocks. On the other hand, strongly supramaximal shocks fatigue the "tonic" muscle more readily than the "non-tonic." The amplitude of the twitches of the fatigued, contractured "tonic muscle" is increased by repeated stretching. This is not the case in the "non-tonic" muscle which shows no contracture.—*G. P. McCouch.*

1091. WESTENRIJK, N. Zur Frage der Veränderungen des Blutes und der Blutzirkulation beim Wettschwimmen. *Zeitschr. Klin. Med.* 106(1/2): 178-182. 1927.—Swimming 100 meters caused an increase in heart rate. Lymphocytes and "Stabkernigen" cells increased in the blood and there was an appearance of young cells. Neutrophiles decreased. Swimming one mile caused an appearance of young cells and myelocytes, an increase in "Stabkernigen" and neutrophiles, and a decrease in lymphocytes. Running for 40 km. is necessary to bring about a similar change in the blood picture.—*H. M. Krueger.*

1092. WINTERSTEIN, HANS. The metabolism of the local excitatory process and of the propagated disturbance in nervous tissues. *Science* 71(1851): 641-643. 1930.—Stimulation of frog nerve and dog-fish spinal cord inside a respiratory chamber was found to cause a distinct increase in O intake; stimulating these tissues outside caused no measurable increase. The author believes that the increase in oxidation is only an artificial result of the electrical stimulation. Increased sugar consumption by stimulated nervous tissue, however, he believes to be a true manifestation of physiological excitation.—*J. M. D. Olmsted.*

1093. WÖHLISCH, EDGAR. Muskelkontraktion, chemische Kontraktur und Totenstarre. [Muscle contraction, chemical contracture, and rigor mortis.] *Naturwiss.* 18 (45): 931-934. 1930.—The author gives a comprehensive presentation of his previously published conception of the mode of action of acids on muscles. Acids in themselves are unable to shorten the muscle fibrils. The so-called acid contracture of muscle is probably due to shortening of the collagen fibrils by acid action. The thermoelastic behavior of muscles in rigor mortis led the author to discard the acid theory of its production. The conception that acid contracture is really a collagen contracture received confirmation in the experiments of P. Weiss on the tail musculature of *Ciona intestinalis,* which, known to be collagen-free, suffers no contracture in acids, but does give a characteristic chloroform contracture.—*E. Wöhlisch (transl. by F. F. Heyroth).*

1094. ALLEN, WILLIAM F. An experimentally produced premature systolic arhythmia (Pulsus bigeminus) in rabbits. II. Secondary factors which do not produce it. *Amer. Jour. Physiol.* 95(1): 190-201. 1930.—Closure of the trachea and inhalation of air with high CO_2 for the same and much longer periods than are represented by the arrest of respiration in insufflation tests have not produced a bigeminal pulse. Apnea following forced artificial respiration has not evoked a bigeminal arhythmia. A bigeminal pulse is readily obtained from benzol insufflation in rabbits having a double pneumothorax and artificial respiration. A bombardment of sudden rises in blood pressure from compression of the aorta or adrenalin has not effected a bigeminal pulse. These rises in pressure were identical or more pronounced and of longer duration than the rise following benzol insufflation. A bigeminal pulse is elicited from benzol insufflation in rabbits in which blood pressure

was prevented from rising—a, by use of an equalizer; b, by ergotamine; c, by sectioning the spinal cord in the middle thoracic region. Asphyxia from occlusion of the trachea causes a more pronounced pulse than insufflation of benzol and there is no arhythmia. Many bigeminal pulse arhythmias have been obtained from benzol insufflation without any preceding alteration of the pulse. The normal reaction of blood pressure to benzol insufflation is not one generally associated with the production of anemia in the brain. Crossed circulation experiments show that there are no substances in the blood of a rabbit having an experimentally produced bigeminal pulse which will call forth a similar arhythmia in a 2nd rabbit. Stimulation of the carotid sinus by mechanically produced rises in blood pressure has not caused a bigeminal arhythmia. A bigeminal arhythmia is easily obtained from benzol insufflation or mechanical stimulation of the nasal septum in rabbits having their carotid sinuses extirpated or the sinuses denervated and ligated above and below. So it appears that asphyxia, mechanical or lack of mechanical stimulation from the arrest of respiration, sudden changes in blood pressure and pulse, brain anemia, secretions or other substances in the blood are not secondary factors for eliciting a bigeminal pulse in the insufflation experiments. If this is true, this arhythmia must be produced by direct nervous influence on the heart. In the insufflation experiments there is no evidence that the carotid sinus functions as an afferent center for producing an arhythmia.—*Author's summary and conclusions.*

1095. **APPELROT, SAMUEL, and A. J. CARLSON. The influence of the vago-sympathetic nerves on the ventriculo-aortic tonus in the turtle.** *Amer. Jour. Physiol.* 95(1): 56-63. 1930.—Independent ventriculo-aortic tonus waves were recorded in the turtle preparation described [from *Emys blandingii*]. The ventriculo-aortic tonus waves are not influenced by stimulation of the vago-sympathetic nerves. Temperature elevation causes an increase of the ventriculo-aortic tonus waves, while cold has the opposite effect. The most favorable temp. for the tonus mechanism is higher than that for the other forms of cardiac rhythm. Co_2 in high concentration stimulates the ventriculo-aortic tonus mechanism. High concentration of O has no effect on the tonus. Adrenalin in concentrations used causes a depression of the tonus mechanism. Ergotamine has no effect.—*Authors' conclusions.*

1096. **APPELROT, SAMUEL. Sex and seasonal variations in excitability of the cardio-inhibitory mechanism of frogs and toads.** *Amer. Jour. Physiol.* 95(1): 242-249. 1930.—Vagal stimulation on the heart in *situ* in 58 toads and 42 frogs showed sex differences in response (more marked and consistent cardiac inhibition in ♀♀). A possible explanation of the occasional occurrence of inhibition in ♂ hearts is suggested in Cheng's finding of ovarian elements among the testicular tissues of normal ♂ frogs. Refractory hearts of 10 ♂ and 10 ♀ frogs could be sensitized to give an inhibition response by pouring over them crude extract of (in order of decreasing effectiveness) heart, liver, brain, skeletal muscle, ovaries or lungs of responsive frogs; control extracts of 5 refractory hearts did not so sensitize other refractory hearts.

1097. **BARCROFT, JOSEPH, and J. J. IZQUIERDO. The relation of temperature to the pulse rate of the frog.** *Jour. Physiol.* 71(2): 145-155. 1931.—The effects of temp. on the excised heart were compared with that on the pulse rate in the intact animal, differences, if any, were observed, and tests were made to determine whether these differences were due to nervous influences. The excised frog's heart studied in winter usually gave a linear relationship between the logarithm of the frequency of the sinus beat and the reciprocal of the absolute temp. between 5° and 20° C. The value of Q_{10} varied in the minority of cases, as the temp. rose the frequency decreased as compared with the above relationship. Most of these cases could be claimed by Crozier as examples of one or other of his patterns, but they did not all conform to the same pattern. In the intact frog in winter the results were irregular. The excised heart of the frog in summer showed a different property. The frequency bore a nearly linear relation to the temp. This was true also of the heart of the intact frog. The relation of the frequency to the temp. was little, if at all, influenced by doses of atropine of the strength which just sufficed to block the vagus. Results confirm those of observers who regard vagus tone as practically absent in the heart of the resting frog.

1098. **BATSON, OSCAR V., and SAMUEL BELLET. The reversal of flow in the cardiac veins.** *Amer. Heart Jour.* 6(2): 206-224. 8 fig. 1930.—The myocardial capillary bed has 3 sets of connecting vessels. Named in the order of their embryological appearance and function these are: the sinusoidal vessels (in which are included the Thebesian veins), the cardiac veins, and the coronary arteries. With the elimination of the arteries as in double coronary occlusion, the mode of irrigation of the capillaries has not been understood. The direction of flow in the cardiac vessels joining the right heart was investigated under conditions simulating double coronary artery occlusion. Particles too large to pass through the lungs were injected into the veins, toward the heart, in [9] anesthetized, heparinized dogs. These particles were uniformly found in the coronary sinus and the coronary veins. Their size was too great, and the arborizing and anastomosing veins were too small to allow for any course of flow other than from right atrium to veins. The sinusoidal vessels (Thebesian veins) were excluded as a possible source of these particles in the veins, although irrigation of the capillaries in part, by them, was not excluded. With a low pressure in the capillary bed (as in cases of double coronary occlusion or as in the authors' experiments), flow in the veins during atrial systole is probably toward the capillary bed, the capillary bed being emptied during the ensuing ventricular systole. In arterial occlusion this would give a flow and ebb circulation for the myocardial capillaries by way of the veins. This irrigation by venous channels may explain the disappearance of pain in angina pectoris, with the inception of complications accompanied by a fall in the coronary artery pressure.—*Authors' summary.*

1099. **BIETER, RAYMOND N., and F. H. SCOTT. Blood pressure and plasma protein determinations in the same frog.** *Amer. Jour. Physiol.* 91(1): 265-274. 1 fig. 1929.—A new method for obtaining values of blood pressure in the intact frog is described. The findings obtained by this method are thought to be within the limits of error since they have been confirmed by blood pressure tracings produced with calibrated Huerthle and Harvard membrane manometers. Normal blood pressure in frogs shows an average blood pressure for *Rana pipiens* equal to 30.5/21.1 mm. Hg, and for *Rana catesbiana*, 32/21.2 mm. Hg. Blood pressure values in frogs show rather marked variations as a result of struggling and excitement, as is the case in mammals and man. Plasma protein percentages obtained by precipitation with trichloracetic acid show for *R. pipiens* an average of 2.71 and for *R. catesbiana* an average of 3.83. Plasma proteins and blood pressures in frogs tend to show some variations, but the variations in a given frog seem to affect both values in the same direction. Fluid drawn into the blood in frogs after hemorrhage appears to be protein-free as in mammals. The findings of Hayman (1927) for general systolic blood pressures in frogs have been confirmed. The averages given here are higher than those of Hayman, however. This, in all probability, is due to the fact that the frogs used by Hayman were anesthetized, or pithed, and prepared surgically for the observations. Such procedures tend to reduce the general blood pressure. There is sufficient diastolic blood pressure in the frog to over-balance the osmotic pressure of the proteins. Using Hayman's figure to determine diastolic glomerular capillary pressure, there is again sufficient blood pressure to over-balance the osmotic pressure of the proteins.—*Authors' summary.*

1100. BLALOCK, ALFRED. Observation upon the blood flow through skeletal muscle by the use of the hot wire anemometer. *Amer. Jour. Physiol.* 95(3): 554-560. 2 fig. 1930.—The alterations in the flow of blood to and from skeletal muscles which were caused by stimulation of the motor nerve have been determined by the use of the hot wire anemometer [on the hind legs of the frog and the gastrocnemius of the dog]. Muscular contraction produced by a single stimulus produces a momentary diminution in arterial inflow and increase in venous outflow. Tetanic contraction is associated with a decrease in arterial inflow as long as the muscle remains contracted and an initial increase in outflow followed by an almost complete cessation of flow. Relaxation of the muscle is followed by a greater flow than existed before the stimulation. If the muscle is stimulated until fatigued, there is an increase in both arterial inflow and venous outflow. Division of the nerve to a muscle greatly increases the flow of blood through it. If sufficiently heavy weights are suspended from the tendon of a muscle, the flow of blood through the muscle almost completely stops. The flow increases when the weights are lifted. Although the vasomotor nerves are responsible for a small part of the alterations in flow produced by stimulation of the nerves to muscles, the major effects are due to the mechanical shortening and lengthening of the muscle fibers. The effects of contraction upon the flow of blood are similar in cardiac and skeletal muscles.—*Author's summary.*

1101. BLUMGART, HERRMAN L., SAMUEL L. GARGILL, and DOROTHY ROURKE GILLIGAN. Studies on the velocity of blood flow. XIII. The circulatory response to thyrotoxicosis. XIV. The circulation in myxedema with a comparison of the velocity of blood flow in myxedema and thyrotoxicosis. XV. The velocity of blood flow and other aspects of the circulation in patients with "primary" and secondary anemia and in two patients with polycythemia vera. *Jour. Clin. Investigation* 9(1): 69-89; 91-106; (4): 679-692. 1930/1931.—XIII. Measurements (27 series) were made in 13 patients with thyrotoxicosis in order to correlate the clinical manifestations with changes in the velocity of blood flow through the lungs, the basal metabolic rate, pulse rate, venous and arterial pressures and vital capacity of the lungs. Measurements made when the basal metabolic rate was elevated were compared with subsequent measurements when the rate was reduced. There was a general but inexact relation between the degree of elevation of the pulse rate and the increase in the basal metabolic rate. No significant deviations from the normal were observed in the venous blood pressure before or after treatment. Diminution in the vital capacity of the lungs was an inconstant finding. With a decrease in the basal metabolic rate, the vital capacity of the lungs tended to increase. The velocity of blood flow was strikingly increased so that the pulmonary circulation time was the fastest yet recorded in man. The increase in velocity of blood flow through the lungs was proportional to the degree of elevation in the basal metabolic rate. This emphasizes the strain under which the heart labors in thyrotoxicosis. In 9 patients with thyrotoxicosis but without circulatory failure, the basal metabolic rate averaged 33% above normal, while the velocity of blood flow through the lungs averaged 83% above the normal. In 4 thyrotoxic patients with similar basal metabolic rates but with cardiovascular disease, the velocity of blood flow was slightly slower. The fact that the latter group of patients experienced dyspnea on slight exertion emphasizes the close interdependence of the circulatory-respiratory-metabolic mechanism. When the basal metabolic rate was lowered by the administration of compound solution of I or by operation, the velocity of blood flow was correspondingly slowed. XIV. Measurements (16 series) were made in 7 patients with myxedema in order to correlate the clinical manifestations with changes in the velocity of blood flow, basal metabolic rate, pulse rate, plasma volume, venous and arterial pressures, respiratory minute volume and vital capacity of the lungs. In each patient measurements when the basal metabolic rate was low were compared with subsequent measurements when the basal metabolic rate had been elevated to normal by appropriate doses of thyroid gland by mouth. The plasma volume per kgm. of body weight was low and tended to increase on administration of thyroid gland. The pulse rate was low and bore a rough relationship to the basal metabolic rate. As the metabolism rose the pulse rate approached normal. The venous pressure was within the limits of normal in all 7 patients. XV. The degree to which increased blood flow compensates for a deficient concentration of hemoglobin was studied in patients with pernicious anemia, with secondary anemia and carcinoma, and with secondary anemia due to causes other than carcinoma. Complete series of measurements (32) of the vital capacity of the lungs, the blood plasma volume, the pulse rate, the arterial and venous blood pressures, and the velocity of blood flow through the lungs and from the arm to the heart were made in 29 subjects. In patients with "primary" anemia or with secondary anemia not due to carcinoma, the velocity of blood flow through the lungs tended to increase in proportion to the degree of anemia. The increased burden on the cardiovascular system is accentuated by exertion and serves to explain the frequent presence of dyspnea in severely anemic patients and also the alleviation of angina pectoris in such patients after improvement in the condition of the blood. The average concentration of hemoglobin was practically the same in patients with anemia due to carcinoma as in patients with pernicious anemia but the velocity of pulmonary blood flow in the former group was relatively slower. This serves to explain why symptoms such as dyspnea, signs of congestive failure, peripheral edema, weakness and cynosis are frequently more pronounced in patients with carcinoma than one would expect on the basis simply of anemia, malnutrition or toxicity. In contrast to the unusually rapid blood flow in patients with anemia, 2 subjects with polycythemia vera showed definite retardation of the blood flow below the average normal; the characteristics of the blood in this condition are the reverse of those present in anemia and the circulatory adjustment is correspondingly altered. In a previous study of the velocity of blood flow and related functions of the circulation in pulmonary emphysema evidence was presented which suggested that the circulation was accelerated to compensate for the defect in "external respiration." In this communication evidence is presented which indicates that, similarly, in patients with anemia, the circulation is accelerated to compensate for failure of the "internal respiration."—*Authors' summaries and conclusions.*

1102. BORCHARDT, W. Die Bedeutung der Gefässreaktionen des peripheren und des Splanchnicusgebietes für den Tropenbewohner. *Arch. Schiffs- u. Tropen-Hyg.* 35(2): 69-73. 1931.—With increased blood supply to peripheral vessels in persons living under tropical conditions the venous blood is light red in color. This is considered due to the diminution in local metabolism caused by exposure to tropical heat. The important question is, where does the increased blood supply come from and by what means is the redistribution accomplished? The author repeated the experiments of others under conditions simulating in so far as heat and moisture were concerned those encountered in a tropical climate. He adopted the method of partial or differential weighing, i.e., the individual was so arranged that variations in the weight of 3 segments of the body could be noted on kymographs. These segments were the head and chest, abdomen and pelvis and finally the lower extremities. Temperature was maintained at 33°-34° C. with a saturation of 90-95% during each experiment. Borchardt found that heat stimuli caused a redistribution of the blood in the sense that it was released from the internal organs and flooded the peripheral areas of head, thorax and extremities. The conclusion is that this readjustment is

caused by a reflex contraction of the vessels of the splanchnic area and represents a protective mechanism, which is physiological in contradistinction to the widely accepted physical conception of heat regulation.—*L. C. Scott.*

1103. BRADBURN, HUBERT B., and ALFRED BLALOCK. The relationship of changes in blood-flow through an extremity to (1) changes in temperature of tissues, (2) differences in oxygen content of the arterial and venous blood, and (3) cardiac output. *Amer. Jour. Physiol.* 91(1): 115-122. 1929.—Changes in temp. in any area of the leg do not bear any constant relationship to alterations of (a) total flow of blood through the entire extremity, or (b) difference in O content of the blood from the femoral artery and vein, or (c) total O consumption of the body, or (d) output of the heart. It is thought that the temp. of any particular area is an index of the flow through that part. Changes in the difference in the O content of blood from the femoral artery and vein indicate alterations in the flow of blood through the leg but the relationship between these changes is not always proportional. In these experiments alterations in the flow of blood through the leg parallel roughly changes in cardiac output but bear no relationship to the small variations in the O consumption of the body.—*Authors' summary.*

1104. CLARK, A. J., C. P. STEWART, and R. GADDIE. The metabolism of the frog's isolated heart. *Proc. Roy. Soc. Edinburgh* 50(3): 297-303. 1929-1930.—The authors measured the respiratory exchange of the isolated frog's heart, and also estimated the carbohydrate and fat content of the hearts and perfusion fluids. The isolated heart of the frog used very little carbohydrate. Even in the presence of serum, glucose and insulin the oxidation of carbohydrate represented less than 20% of the total metabolism and the respiratory quotient was less than 0.9. The perfused frog's heart excreted nitrogenous compounds into the Ringer's fluid and the quantity excreted was sufficient to account for about half the O consumed. There was no evidence for oxidation of fats.—*A. J. Clark.*

1105. CLARK, G. A. The selective vaso-constrictor action of pituitary pressor extract. *Jour. Physiol.* 70(1): 53-59. 1930.—In anesthetized cats injection of the pressor fraction of posterior pituitary extract invariably caused intense pallor of the intestine, the degree of blanching being much greater than that after an injection of adrenalin which produced an equal or even a greater rise in general blood-pressure. This last observation suggested that the redistribution of blood in the body following injection of pitressin might differ from that after adrenalin. An investigation was therefore begun, using the plethysmographic methods described earlier. The majority of experiments were made on cats anesthetized with chloralose, but observations were also made on cats under amytal or urethane anesthesia and on decerebrated cats; both vagi were cut in all cases. Results indicate that pituitary pressor extract (pitressin) given intravenously to cats, anesthetized with chloralose or decerebrated, causes a redistribution of blood in the body so that the intestine contains much less and the muscles contain more; the skin and connective tissues usually contain less, but, if the blood-pressure is greatly increased, may contain more. The increase in volume of muscle (and in skin and connective tissue when it occurs in the latter 2 tissues) is due not to active dilatation by pitressin but to the greater degree of constriction in the intestine together with, in some cases, increased cardiac activity. This increased cardiac activity is probably an indirect effect, produced by improvement in the venous return to the heart.

1106. CSINÁDY, E. v. Sportärztliche Untersuchungen. III. Vergleichende elektrokardiographische Untersuchungen an Sporttreibenden, bei besonderer Berücksichtigung der "Ekg"-Zeitwerte. *Arbeitsphysiologie* 3(7): 579-595. 1 fig. 1930.—Electrocardiograms were made of 54 subjects after 1 hr.'s rest in leads I, II, and III and again in lead II after a functional test of 20 knee bendings. Three groups were studied: 1, controls; 2, mixed group of athletes subdivided into 3 groups according to the intensity of the sport; and 3, swimmers, beginners and trained. The results of the investigations showed that the heart frequency was in general lower with the athletes, and not infrequently lower after the functional test. Not infrequently a saddle formed depression was seen in the T wave. The conduction time was longer in athletes than in subjects who had not participated in sport. This difference was specially significant in the swimmers, in whom frequently the conduction time was even increased after the functional test. The time of the T wave (end of S to end of T) was extraordinarily long with the swimmers. After the functional test, it was always of shorter duration. After a long period of rest, these changes underwent a recurrence during activity. These alterations were first recognized through the use of the functional test. It appears desirable for athletic organizations, as well as for the sake of the athlete himself, that intensive training should be conducted under medical supervision.—*T. M. Carpenter.*

1107. DALE, ALISON S. A reversed action of the chorda tympani on the venous outflow from the submaxillary gland. *Jour. Physiol.* 70(4): 449-454. 1930.—Experiments on cats confirmed the observations of Fröhlich and Loewi that stimulation of the chorda tympani during the action of amyl nitrite may retard the venous outflow from the submaxillary gland (in 12 out of 13 cases here). In 16 experiments lowering of arterial tone by other means (histamine, over-ventilation, etc.), produced the same effect. The diminished venous outflow is accounted for by loss of fluid from the blood to the saliva. The action of amyl nitrite affords no adequate evidence of vaso-constrictor fibres in the chorda tympani.

1108. DALE, ALISON S. The relation between amplitude of contraction and rate of rhythm in the mammalian ventricle. (Including interpretation of the apparent indirect action of the vagus on amplitude of ventricular contraction.) *Jour. Physiol.* 70(4): 455-473. 2 fig. 1930.—The experiments were performed, with 1 exception (cat's heart), on the hearts of rabbits. The drug used in most of the experiments was arecoline, though acetylcholine was occasionally used. Cullis and Tribe's observation, that vago-mimetic drugs diminish the amplitude of contraction of the rabbit's ventricle only when the A.-V. bundle is intact, was confirmed. This action was shown to depend on the fact that the S.-A. nodal rhythm was slowed by the action of the drug, while the idio-ventricular rhythm which obtained after section of the A.-V. bundle was not affected, similar diminutions of amplitude being observed when the rhythm was slowed by other means. A diminution was also obtained in the amplitude of contraction of perfused ventricular strips, stimulated artificially, when the rate of stimulation was diminished. This relation between the amplitude of contraction and the rhythm is ascribed to a form of Bowditch staircase.

1109. DIXON, W. E., and J. C. HOYLE. Studies in pulmonary circulation. III. The action of histamine. *Jour. Physiol.* 70(1): 1-17. 1930.—Illustrative experiments are cited (presumably from a more extensive series), showing that the action of histamine presents great differences in the dog, cat and rabbit; some of these can be explained by gross anatomical differences, but in others the explanation is more difficult, since the same type of structure in different animals responds to histamine differently. Deductions therefore made on the basis of experiments carried out on 1 species do not hold in others. In the dog the venae hepaticae are provided with thick muscular coats and are very sensitive to histamine. This action of histamine by limiting the return of blood to the right heart is responsible for all the pulmonary changes which the authors describe. In the cat and rabbit Mautner and Pick showed that liver obstruction is of little moment. Other views have been expressed by Ganter and Schretzenmayr in opposition to those of Dale and Pick. In the cat the action of histamine on the pulmonary circulation is exactly opposite to that on the dog. Histamine dilates the

coronaries of this animal, while it constricts them in the dog and rabbit. This dilatation accounts for the increased right auricular pressure and the subsequent congestion of the whole pulmonary circulation, including increased blood-flow into the left auricle. Dixon and Hoyle think that, in the later stages of the action, when the right auricular pressure falls, some retardation of blood through hepatic-portal veins occurs which causes this fall of pressure, and in support of this increased portal pressures are shown. In the rabbit, the authors, like other observers, obtained no evidence of damming back of blood in the liver. The right auricular pressure remains raised during the entire action of histamine, in contrast with the dog in which it is lowered throughout, and in the cat in which it is first raised and then lowered. The action of histamine in the rabbit is thus mainly determined by its effect in constricting the pulmonary vessels.

1110. DUBUISSON, M., et A. M. MONNIER. L'electrocardiogramme de Limulus polyphemus étudié au moyen de l'oscillographe cathodique. *Arch. Internat. Physiol.* 33 (3): 282-299. 1 pl. 1931.—In observations on an unspecified number of horseshoe crabs the authors found (contrary to Hoffmann) that the normal electrocardiogram presents striking analogies with that of vertebrates, with no oscillations under normal conditions. It is composed of a definite number of deflexions: rapid QRS (or R) preceding the cardiac contraction and T, slow and synchronous with the contractions. The R wave has a very constant form, whatever the complexity of the T wave, which, on the contrary, is very labile, its amplitude and duration expressing more or less faithfully the mechanical activity of the heart. When the ganglionic nerve has been injured, the myocardial contractions are no longer simultaneous in all the regions of the muscle. In this case, the T wave is polyphasic, comprising a greater number of peaks, the more accentuated the lack of synchronization of the pulsations. Hence it would seem that R and T represent, not respectively the beginning and the end of a single electric manifestation, but 2 manifestations of different origin. R would thus represent an electric manifestation of unknown origin, at the end of which a visible reaction of the myocardium occurs. The monophasic wave T would be an epiphenomenon, a physical repercussion of the visible reactions of the myocardium. The variations in amplitude and sign of the R and T waves between one subject and another or between one position and another of the electrodes were explained by the existence of a dissymmetry of shunt of the 2 cardiac territories situated under the electrodes.

1111. EYSTER, J. A. E., and WALTER J. MEEK. Studies on venous pressure. *Amer. Jour. Physiol.* 95(2): 294-301. 1930.—In 22 experiments on 8 dogs under anesthesia, venous pressure tended to show relatively small and transitory changes under conditions which alter markedly the physical conditions existing in the cardiovascular system. There appear to be compensatory factors present tending to prevent excessive changes and to cause rapid restoration to a normal level. There appears to be little if any direct relation between arterial pressure and the pressures in different parts of the venous system. Inverse changes occur as frequently as direct, and both may be present simultaneously if different parts of the venous system are considered. In general the pressure is more stable and less subject to alteration in the peripheral veins (iliac and jugular) than in the right auricle. There appear to be some factors tending to reduce the extent of change arising at the heart as measured further out in the vascular system. Not infrequently inverse changes may occur in the periphery as compared with the auricular pressure change, but in all cases the result is transitory and rapid readjustment occurs. These results tend to emphasize the fact that the vascular system, particularly the venous part, cannot be reduplicated physically by a simple hydraulic model. Many factors, some unknown and some only partially recognized, modify markedly the comparison to a more or less static system of channels. Two of these factors, the varying response of the heart to varying venous loads and the variable capacity of the vascular bed, would seem to be of essential importance.

1112. FLEISCH, ALFRED. Venomotorenzentrum und Venenreflexe. II. Mitteilung. Blutdruckzügler und Venenreflexe. *Pflüger's Arch. Ges. Physiol.* 226(3): 393-410. 10 fig. 1930.—In a dog or cat a mesenteric vein was separated from its connecting vessels, fixed in such a way that the resistance to flow through it would not be affected by extraneous conditions, and then perfused artificially. The flow through this vein was recorded by the author's differential pressure stromuhr and was found to be altered by reflex changes in the diameter of the vein. Records of flow and of arterial pressure were obtained photographically. Although the vessel was separated from the circulation, inspiration of CO_2 (2% or greater) caused a constriction of the vessel and decreased flow. Rise of pressure in the carotid sinus caused a reflex dilatation and vice-versa. Stimulation of the central end of the vagus gave venodilatation (depressor reflex), of the peripheral end alternating dilatation and constriction, or sometimes a pure dilatation.—*H. C. Bazett.*

1114. GILSON, A. S., JR., and E. IRVINE-JONES. The effect of repetitive stimulation upon the duration of the electrical response of ventricular muscle. *Amer. Jour. Physiol.* 92(1): 160-164. 2 fig. 1930.—The experiments reported were made on ventricular strips of turtle heart. The strength of stimulation selected was 5 to 10% above threshold at the beginning of the experiment. The chief changes seen in the electrogram as the result of continuous stimulation are a slowing of conduction and a shortening of the R-T interval. The rate of stimulation of the strip determines the rate at which these changes occur. These changes are recovered from more or less completely during resting periods. Treppe may be observed as regards conduction and duration of the sustained electrical response. Treppe is manifested by a shortening of the conduction time and a lengthening of the period of electrical response for a few beats. A short discussion of the effects of temperatures on the treppe of the R-T interval is given.—*G. Bachmann.*

1115. GRANT, R T. Observations on local arterial reactions in the rabbit's ear. *Heart* 15(3): 257-280. 1930. —Observations on 14 rabbits each with 1 ear denervated and 1 ear normal indicated that the arteries of the rabbit's ear respond to increasing degrees of mechanical stimulation of the skin over them by increasingly complex local reactions: (a) A light touch causes transient dilatation; (b) moderate pressure causes constriction of the length of vessel pressed on with dilatation on each side; the constricted portion subsequently dilates before returning to normal; (c) firm pressure causes dilatation of the length of vessel pressed on with constriction on each side and dilatation on each side beyond the constrictions. The constricted portions subsequently dilate before returning to normal, the central dilatation persists for a long time; (d) pricking the skin near an artery causes in the larger arteries dilatation and constriction followed by oscillations in calibre; in the smaller arteries dilatation alone results. These reactions are all independent of the nervous system. Firm pressure on, and pricking of, the skin also cause (1) dilatation of the artery beyond the local reaction, this dilatation being dependent on a local nervous mechanism; (2) dilatation of the minute vessels and local edema. The arterial reaction to pricking is in large part attributable to the action of a histamine-like substance released from the tissues by the injury. The arterial reactions to light touch and moderate pressure and the local response to firm pressure cannot be explained in this way. Histamine applied to the larger arteries causes constriction followed by oscillations in calibre; applied to the smaller arteries it produces dilatation alone; these reactions are independent of the nervous system. Histamine also causes (1) dilatation of the artery be-

yond the local reaction by means of a local nervous mechanism, and (2) dilatation of the minute vessels and local edema. An extract of rabbit's skin was found to contain a histamine-like substance and called forth the same vascular responses as histamine itself. The vascular reaction to injury in the rabbit's ear is essentially the same as that in human skin. Acetylcholine applied to the arteries causes conspicuous local dilatation which is abolished by either local or general administration of atropine; it is independent of the nervous system. Adrenalin applied locally produces intense arterial constriction followed by oscillations in calibre; the oscillations are local in origin. Adrenalin so applied does not produce appreciable arterial dilatation.—*Author's summary and conclusions.*

1116. GRIFFITH, FRED R. Jr., and F. E. EMERY. The vasomotor control of the liver circulation. *Amer. Jour. Physiol.* 95(1): 20-34. 1 fig. 1930.—By the use of a special plethysmograph which permits records to be taken of the volume of the entire liver the following have been established in regard to the vaso-motor control of the hepatic circulation: (1) Stimulation of the post-ganglionic fibers along the hepatoduodenal artery or of the pre-ganglionic fibers of the splanchnic nerve causes constriction of the terminations of the hepatic artery and of the portal vein. (2) Stimulation of the peripheral vagus has no effect on liver volume. (3) The liver constricts during pressor and dilates during depressor reflexes; both reactions are abolished by cutting the postganglionic fibers of the hepatic plexus. (4) The liver constricts powerfully during asphyxia; this is inaugurated through its nerves and reinforced and sustained by the asphyxial secretion of epinephrine. (5) Hemorrhage induces a contraction of liver volume which may be sufficient to sustain the blood pressure; this reaction, too, is abolished by section of the hepatic plexus.—*Authors' summary.*

1117. GROLLMAN, ARTHUR. Physiological variations of the cardiac output in man. X. The effect of variations in the environmental temperature on the pulse rate, blood pressure, oxygen consumption, arterio-venous oxygen difference, and cardiac output of normal individuals. XI. The pulse rate, blood pressure, oxygen consumption, arterio-venous oxygen difference, and cardiac output of man during normal nocturnal sleep. *Amer. Jour. Physiol.* 95(2): 263-273; 274-284. 1930.—X. A study was made of the cardiovascular and metabolic changes occurring in 5 normal human subjects over a temp. range of 0° to 45° C. The pulse rate rises progressively with increasing temp., the changes below room temp. being slight. The blood pressure undergoes a change of only about 10% throughout this range with only slight variations in the pulse pressure. The metabolism declines with increasing temp., to a minimum, at about 30°, after which it again rises slowly. The nature of these changes in the metabolism and their probable causation is discussed. The cardiac output is constant over the temp. range of 0° to about 28°. At temperatures over 28° the cardiac output gradually increases with increasing temp., giving at 45° a value (for the average sized individual) 1.3 liters above the value at normal room temp. These effects of temp. on the cardiac output are explained as being the resultants of 2 diverse phenomena. The constancy of the cardiac output with moderate degrees of cold is analogous to its constancy with slight muscular activity. The increase at higher temp. represents the peripheral dilatation occurring under these conditions. The effect of baths (as compared to air as the environmental medium) and the possible differences to be encountered in pathological cases are also discussed. The bearing of the present results and those obtained on other animals on the theory of the calorigenic function of epinephrine is indicated. XI. The pulse rate, blood pressure, O consumption, and cardiac output of 3 normal, young individuals were determined in the sleeping and waking states throughout the course of the night. If one compares the values of the above-named functions during sleep with those obtained a few min. later, after awakening the subject, one finds that only the pulse rate rises as a result of awakening the subject. This is attributed to the lability of the pulse and its stimulation by the optic and acoustic stimuli which are active when the subject is awake. The sleeping state per se is not associated with a decrease in the blood pressure, O consumption, or cardiac output, as compared to the waking state under completely relaxed conditions at the same hr. of the night. These functions assume sub-basal values (i.e., lower than the minimum values obtained under optimum conditions of rest during the day) after 5 or 6 hrs. of sleep. The observed changes in the cardio-vascular and metabolic functions during sleep are either incidental to the prolonged bodily rest associated with this state or are a manifestation of cyclic changes in the organism of the nature of a diurnal rhythm.—*Author's summaries.*

1118. GROLLMAN, ARTHUR. Physiological variations in the cardiac output of man. XII. The effect of the menstrual cycle on the cardiac output, pulse rate, blood pressure, and oxygen consumption of a normal woman. XIII. The effect of mild muscular exercise on the cardiac output. *Amer. Jour. Physiol.* 96(1): 1-7; 8-15. 1931.—XII. A study was made of the variations of the pulse rate, blood pressure, O consumption, and cardiac output in relation to the catamenial cycle [in a healthy, nulliparous, married woman, aged 28]. No definite menstrual variations in these functions were observed despite the extra precautions taken to attain perfect basal conditions and the avoidance of all known vitiating factors. The pulse rate varied from 48 to 55 during the cycle and showed periodic and regular changes whose significance, however, was minimized. The blood pressure was extremely constant throughout the cycle; O consumption varied from 180 to 214 ccm. per min. but no definite relationship between these variations and the menstrual cycle could be demonstrated. The cardiac output showed a constancy from day to day within 5% of the mean value, which variation was well within the predictable experimental error. It was concluded that variations in the metabolic and cardio-vascular functions bear no simple rhythmic relationship to the catamenial cycle, as has often been maintained. XIII. A study was made of the cardiac output during very mild muscular activity [in a single subject, age and sex not stated]. The cardiac output in such exercise bears no simple relation to the O consumption. Active muscular movements result in a much greater increase of the cardiac output than static or slow movements. This is explained as due to the greater pumping action of the muscles in the former exercises which causes a greater return of venous blood to the heart.—*Author's summaries.*

1120. HAMILTON, W. F. Filling of the normal human heart in relation to the cardio-pneumogram and abdominal plethysmogram. *Amer. Jour. Physiol.* 91(2): 712-719. 1930.—Study of the changes produced in the intrathoracic pressure of man by the cardiac movements indicates that during ventricular systole an amount of blood nearly equal to the systolic discharge enters the auricles and that little or no blood flows to the heart during diastole. Some theoretical implications of these findings are discussed.—*Author's summary.*

1121. HAMILTON, W. F., M. C. SPRADLIN, and H. G. SAAM, Jr. The CO_2 of the mixed venous blood of man. *Jour. Physiol.* 70(3): 244-252. 1930.—The contention that the CO_2 tension of re-breathed air equals that of venous blood is re-examined in the light of the recent literature and new evidence cited here. No valid evidence, from either of these sources, can be found that re-breathed air comes to equilibrium with mixed venous blood, and hence doubt is left as to the justification for using any of the indirect applications of the prin-

ciple of Fick in determining the output of the human heart.—*Authors' summary.*

1122. **IZQUIERDO, J. J. The influence of sympathetic stimulation upon intra-auricular block in the mammalian heart.** *Amer. Jour. Physiol.* 91(2): 696-711. 1 fig. 1930.—As intra-auricular block has been found to be relieved by sympathetic stimulation in the cold-blooded heart and by stimulation of the vagus nerve in the mammalian heart, the effects of stimulating the sympathetic nerves upon conduction through mammalian auricular muscle have been investigated. The effects usually associated with right or left sympathetic stimulation have been found to be developed in different hearts in varying degree. Faradic stimulation of the right, left or both sympathetic nerves has no definite effect upon the conduction of the excitation wave through normal or compressed muscle, whether the heart is beating naturally or responding to rhythmic shocks. Atropine must be employed to exclude the effect due to stimulation of vagal fibres accompanying the sympathetic nerves; this drug in the doses employed has no influence upon the effects of sympathetic stimulation. The relief of block already reported as a result of stimulation of the vagus nerve high in the neck, has been duplicated by stimulating the same nerve as it emerges from the skull. The relief of intra-auricular block seen in mammalian hearts after stimulation of the vagus nerve must therefore be, as has already been suggested, a pure vagal effect.—*Author's summary and conclusions.*

1123. **IZQUIERDO, J. J. Influence of the aortic and carotid sinus nerves upon the height and form of the rise of blood-pressure produced by peripheral stimulation of the splanchnic nerve.** *Jour. Physiol.* 70(3): 221-243. 1930.—By stimulating the peripheral end of the splanchnic nerves by a faradic stimulus under similar conditions, first with the 2 sets of aortic and carotid sinus nerves intact and then with these nerves partially or totally eliminated, the following results were obtained: When the aortic and sinus nerves are eliminated the blood-pressure curve is considerably higher and simpler in form than when both sets of nerves are intact. When only the 2 aortic nerves are active the curve is higher and its "dip" less pronounced than when in addition the 2 carotid sinus nerves are in action. When only the 2 carotid sinus nerves are active the height reached by the curve is higher than when in addition the aortic nerves are in action, but its form is not appreciably modified. When a single carotid sinus nerve is left active its effects upon the height and form of the splanchnic pressure curve are often considerable. When both aortic and carotid sinus nerves are active, their joint inhibitory action can be so strong that a stimulation of the splanchnic nerve may fail to give any appreciable rise of blood-pressure. Comparison of the effects observed after elimination of both aortic nerves or both carotid sinus nerves alone, shows that the carotid sinus nerves exert the more important inhibiting effect upon the height of the curve and are the main factors in producing the "dip" in the splanchnic pressure curve. Tying off of both adrenals at the beginning of the experiment or after partial or total suppression of the aortic and carotid sinus nerves does not modify the results in the rabbit, the hare and the dog. But in the cat the "dip" more frequently disappears after the ipsilateral gland is tied off. The 2 variations, namely, in the height and "dip" in the curve, develop simultaneously and in contrary sense, i.e., the gradual attenuation and final disappearance of the "dip" keeps pace with the gradual increase in the height reached by the curve. Therefore, both series of changes are compatible with the view that the curve of the rise of blood-pressure produced by stimulation of the splanchnic nerve consists of 2 superimposed elements, (a) the direct vasopressor effect (vaso-constriction in the splanchnic area), and (b) the indirect vaso-depressor effect (aortic and more especially carotid sinus reflexes) evoked by the rise of blood-pressure.—*Author's conclusions.*

1124. **KATZ, LOUIS N. The rôle played by the ventricular relaxation process in filling the ventricle.** *Amer. Jour. Physiol.* 95(3): 542-553. 3 fig. 1930.—Experiments were made on the isolated turtle ventricle connected to a reservoir, which tended to keep the pressure of the system constant, in order to see what rôle ventricular relaxation played in filling the heart chamber. It was found that during relaxation the pressure within the ventricle dropped below the zero level of the system. The amount of this drop was a direct function of the initial length of the muscle in the range studied. The drop in pressure was not due to an overswing, for when filling was prevented at the onset of relaxation by making relaxation isometric, the pressure drop below the zero level of the system was magnified. Other considerations are discussed which also disprove that it is an artefact. The minimum elastic state of the ventricle can be expressed by a smooth curve, along which the pressure/volume ratios of the relaxed heart fall, regardless of whether the diastolic volume or the diastolic pressure is set. The drop of pressure during relaxation below that set by the reservoir is taken as evidence that the ventricle is drawing in fluid. These experiments are not contradicted by those on skeletal muscle suspended on Hg. The sources of energy for the sucking action are mainly potential stores, created by the contraction process, such as energy of position and of elastic state. The distinction is made between the source of energy for the sucking action and for the flow of fluid. The distinction is shown to be the same as in an aspirating pump. The conclusion is drawn that relaxation is of similar nature to contraction. Both are dependent on some reversible physico-chemical process which alters the elastic state of the muscle between 2 limits, the minimum for the relaxed and the maximum for the contracted heart. Evidence is given to show that the ventricle not only can but does exert a sucking action in the intact mammal.—*Author's summary.*

1125. **KILBORN, LESLIE G. The variability of blood pressure in normal persons.** *China Med. Jour.* 44(6): 533-540. 1930.—Previous observers have reported higher tension in the same subjects when in the U. S. than when in China. Kilborn compared 4 sets of records of the same 51 persons extending over a period of 28 months. He found a range of variation as high as 28 systolic (av. 17) and 30 diastolic and pulse pressures (av. 16), or as great variability as found by others between pressures in the same subject in the U. S. in China. He emphasizes the need for caution before assuming that race, climate or geographical position are the cause of the hypotension reported for China.

1126. **[KONSTANTINOV, B. M.] КОНСТАНТИНОВ, Б. М. О влиянии временного прижатия артерий на отложение трипановой синьки и туши при внутривенозном их введении. [Influence of temporary compression of arteries on the deposit of intravenously injected trypan blue and India ink.]** [French résumé.] Архив Биологических Наук (*Arch. Sci. Biol.*) 30(5/6): 639-650. 1930.—Trypan-blue and India-ink were injected into the auricular vein of rabbits immediately upon removal of the temporary compression of arteries. Vessels chosen for compression were situated in the lower extremities, in the liver and in the spleen. The animals were killed and the organs subjected to anemia, as well as other parts of the body, were microscopically examined. Temporary anemia of these organs resulted in a heightened adsorption of the colloidal dye-substances. After the injection of trypan-blue the diffuse imbibition of the anemic organ was more pronounced, and heightened granular depositions of the dye were found in the reticulo-endothelial system and in the histiocytes. After the injection of India-ink, the author observed only an increase in quantity of the granules deposited in the cells. This is explained by the active post-anemic hyperemia. Attention is called to the fact that temporary compression of the vessels offers many possibilities. In case of certain colloidal substances circulating in the organism—such as toxins, antibodies, etc.—

their fixation is made possible in the organs subjected to temporary anemia.

1127. **KOSTJUKOW, I. I. und S. D. REISELMANN. Änderungen im Elektrokardiogramm nach dosierter körperlicher Arbeit. I.** *Arbeitsphysiologie* 3(5): 415-448. 13 fig. 1930.—Electrocardiograms of porters were taken at rest at the same time each morning 2 hrs. after breakfast. The porters then carried a load of 96 kgm. on their shoulders or back for a stretch of 250 m. in a limited time, dropped the load and reclined. Electrocardiograms were made at once and at intervals of 1, 2 and 3 min. One group consisted of 18 men who were examined only once. Another group consisted of 91 men, 44 of whom performed the same task on 2 separate days, and 47 carried the usual load at the first examination and, at the second, carried the same load until they were fatigued. The most important alterations in the electrocardiograms due to bodily activity were considerable increases in the P and T waves. The changes in these waves were due to altered filling of the heart with blood and the accompanying energetic contractions of the muscle fibers of the myocardium which were caused by increased demands upon the heart brought about by bodily exertion. If one compares the processes occurring in the working heart to the physiological laws, then the heights of the T and P waves are criteria of the functional condition of the heart and the strength of the myocardium. Symptoms of dextrocardia that appear in the electrocardiograms after bodily exertion speak for a weakness of the heart (the left ventricle). In healthy hard working men a significantly well developed T wave is found at rest which indicates the presence of a slightly hypertonic heart and is a sign that the heart is healthy and well adapted to the tasks.—*T. M. Carpenter.*

1128. **LANDIS, EUGENE M. Micro-injection studies of capillary blood pressure in human skin.** *Heart* 15(2): 209-228. 2 fig. 1930.—The micro-injection method for directly determining mean blood pressure in single capillaries has been modified to suit the skin at the base of the human finger nail. Av. blood pressure in the arteriolar limb is 32 mm. Hg, at the end of the loop 20 mm., and in the venous limb 12 mm. The fall of blood pressure does not cease at the junction of the arterioles and capillaries but continues unbroken through the capillary loop. Av. blood pressure in the arteriolar limb is above, and in the venous limb below, the osmotic pressure of the plasma proteins. These direct pressure readings in human capillaries are in agreement with Starling's hypothesis of fluid balance. When the hand is placed at various levels above the suprasternal notch the arteriolar and venous capillary pressures remain almost constant, but with the hand below the suprasternal notch they increase by the increment of hydrostatic pressure. Venous congestion by a pneumatic cuff produces a rapid rise of capillary pressure, which reaches cuff pressure within 15-45 sec. Capillary pressure finally exceeds cuff pressure by 8-14 mm. Hg. Hyperemia of the skin at the base of the nail due to heat is accompanied by a rise of capillary pressure to as much as 60 mm. Hg in the arteriolar limb and to as much as 45 mm. in the venous limb of the capillary. In the histamine flare arteriolar capillary pressure rises to between 32 and 50 mm. Hg, and venous capillary pressure to between 27 and 39 mm. Local cooling of the skin produces first a fall in capillary pressure of 6-11 mm. Hg, and after 5-8 min. a secondary rise of 2-14 mm. above the original normal pressure. When the skin is whealed by freezing, av. capillary pressure rises to 49 mm. Hg in the arteriolar limb and to 32 mm. in the venous limb. In the blister av. arteriolar capillary pressure is 41 mm. Hg, and av. venous capillary pressure 23 mm. Hg. The direct micro-injection method is compared, from the point of view of its accuracy, to direct and indirect methods. The findings are discussed with reference to the mechanism of fluid balance under av. conditions and during hyperemia.—*Author's summary.*

1129. **LEWIS, THOMAS (in successive collaboration with I. HAYNAL, W. KERR, EDWARD STERN, and E. M. LANDIS). Observations upon the reactions of the vessels of the human skin to cold.** *Heart* 15(2): 177-208. 2 fig. 1930.—Experiments (mostly on fingers) extending over 3 yrs. are summarized, showing that a vasodilatation occurs in the skin of the finger after the latter has been immersed in cold water for some time. The reaction usually begins within 5-10 min. of immersion. The vasodilatation continues during immersion, though it varies in its degree, often giving rise to a phasic rise and fall of temp. On withdrawing the finger from water, after the reaction has begun, its temp. rises above that of neighbouring uncooled fingers. This after-effect comes to its maximal point in 15-20 min. and subsides thrice as slowly. The reaction occurs in water at 18 or 15° C. or lower, but is not known at higher temp. In general the lower the temp. the more decided the reaction. The reaction with its after-effect is obtainable unmistakably from fingers and toes, from the ear and some other parts of the face. It can rarely be obtained from the skin of the forearm. Although there is no corresponding rise of temp., vasodilatation in response to cold can be demonstrated in the skin of the forearm by more sensitive methods. The reaction occurs after degeneration of the sympathetic fibers to the skin and after severance of the sensory nerves; but does not occur after degeneration of the sensory nerves has occurred. It is due to a sensory axon nerve reflex. Evidence is given for believing that when the skin is strongly cooled, H-substance is released and awakens this axon reflex. The mechanism described comes into very frequent play in cold weather and has an important function in protecting exposed parts of the skin from excessive cooling and injury. It is suggested that the axon reflex mechanism responding to cold and other stimuli constitutes an important contributory means by which the temp. of exposed parts is normally maintained. Evidence is put forward suggesting that when the sensory nerves to fingers degenerate, the fingers lose their normal blood supply as a consequence, and that this may result, directly or indirectly, in the development of certain so-called trophic lesions.

1130. **LLOYD, WRAY. Experimental heart block in the rabbit.** *Heart* 15(2): 125-127. 1930.—Hearts from 51 rabbits were excised and perfused while still beating and the a.-v. bundle transected anterior to its origin from the a.-v. node. In 2 hearts the ventricle ceased beating; in 3 cases no dissociation followed, and later examination showed that the bundle had not actually been transected; in the remaining 46 cases complete a.-v. dissociation followed section of the bundle stem.

1131. **McDOWALL, R. J. S. The effect of carbon dioxide on the circulation. Part I.** *Jour. Physiol.* 70(3): 301-315. 1930.—Over-ventilation under chloralose has been shown to cause [apparently in cats] 2 effects: dilatation of vessels due to central effect, and the other a constriction of smaller more peripheral vessels due to the effect of washing out CO_2 locally. Either effect may predominate, and the result be a fall, no change, or a rise in blood-pressure. Either abolishes the more peripheral effect. The reaction of the circulation to changes in posture are shown to be profoundly affected by over-ventilation. The evidence suggests that the normal CO_2 of the arterial blood exercises a dilator effect on the more peripheral vessels. Reasons are given which indicate that these results are applicable to normal man. —*Author's summary.*

1132. **PATTEN, BRADLEY M. The changes in circulation following birth.** *Amer. Heart Jour.* 6(2): 192-205. 3 fig. 1930.—Patten concludes that: (1) Current conceptions as to the occurrence at birth of an abrupt rerouting of the blood in the heart and great vessels rest on insufficient evidence. (2) There is increasing reason to believe that the volume of blood circulating through the lungs at the close of fetal life is adequate to care for the respiratory demands of the newborn infant as soon as the lungs are properly ventilated, and that there is no radical circulatory upheaval at the

time of birth. (3) In the neonatal period, with the assumption of respiratory function, the volume and power of the pulmonary circuit gradually increase, bringing about, by the close of the 1st mo., a new functional balance in intracardiac pressure. (4) It is probable that under normal conditions the progressive closure of the ductus arteriosus accelerates the enlargement of the pulmonary vessels following birth, but there are many cases on record where a normal pulmonary circulation has been established without closure of the ductus. (5) With the establishment of the new interatrial equilibrium brought about by increase in pulmonary circulation the foramen ovale falls gradually into disuse. (6) Anatomical obliteration of the foramen ovale follows slowly in the wake of its functional abandonment. Provided the valvula foraminis ovalis competently covers the foramen ovale, failure of the valve completely to fuse to the septum is no functional handicap as long as there is not an intercurrent disturbance elsewhere in the cardiovascular mechanism or in the lungs. This fusion is incomplete, leaving what might be termed a "probe-patency" in about 20% of all adults. Functional incompetence of the valvula by reason of defective development, which should be clearly distinguished from "probe-patency," is as uncommon as other cardiac anomalies. (7) Failure of the ductus arteriosus to close within the normal time range is to be regarded as a symptom rather than a cause of circulatory dysfunction. Instances of the ductus remaining unclosed in the absence of abnormal conditions which force the maintenance of a blood current through it are exceedingly rare. (8) Following the increase in pulmonary circulation and the closure of the fetal blood passages there is a gradual increase in the left ventricular musculature to equal the right at about 3.5 mos., acquires a definite preponderance by the 2nd yr., and its full adult degree of preponderance by about the 7th yr.—*Author's summary.*

1133. PODKAMINSKY, N. A. Beiträge zur pathologischen Arbeitsphysiologie. III. Die Einwirkung der Gewerbearbeit in einer gebeugten Sitzstellung auf die Dimensionen des Herzens. *Arbeitsphysiologie* 3(5): 347-359. 1930.—Measurements of the hearts and lungs of 60 female sewers in a factory in Charkow were made by means of teleröntgenograms at a focus of 2 meters. Blood pressures and pulse rates were also recorded. The workers were accustomed to carry on their tasks in a sitting and bent position. On the average there was found an increase in the minute volume, a certain rise in blood pressure and an enlargement of the transverse diameter at the expense of the dimensions of the left heart. The alterations were characteristic of the group as a whole, but a detailed study of individual cases showed that beside the principal occupational type there were three other types which would explain the varieties of combinations of findings. All comparisons were made with the findings on a group of load carriers studied previously by the same author. The fact that the hearts of women who performed light work in a sitting bent position were enlarged as compared with the hearts of men at severe bodily exertion, speaks for the lack of a so-called work hypertrophy of the heart and for the significance of the effect of occupations upon the size of the heart.—*T. M. Carpenter.*

1134. POLÁK, E. Über den Einfluss radioaktiver Strahlungen auf die automatische Tätigkeit des Froschherzens mit besonderer Rücksicht auf die Wirkung grosser Strahlendosen und auf den Antagonismus der α- und β-Strahlung. *Pflüger's Arch. Ges. Physiol.* 226 (4/5): 659-675. 15 fig. 1931.—H. Zwaardemaker (Erg. Physiol. 1926. 25. 536) has marshaled evidence to show that the importance of K for heart muscle is due largely to its radioactive properties. He has found that an excised heart which has ceased pulsating because of K deficiency will resume beating when subjected to radiation from other sources. The author has repeated these investigations and confirms Zwaardemaker's results. Equimolecular substitution of Rb for K permits normal activity and restores a heart which has stopped in the absence of K. Relatively smaller concentrations of uranyl nitrate are necessary because of its greater radioactivity. Likewise the optimum concentration of radium emanation in Ringer's solution must be still smaller and in addition a new Em-Ca balance must be set up to replace the K-Ca ratio. Other sources of radioactivity behave similarly. Overdosage of K produces a stoppage of contractions which the author ascribes to the effects of high amounts of β-rays. Such poisoning is different from that produced by too much α-radiation. The effects of a K overdose can be neutralized by appropriate α-radiation. Furthermore after poisoning with emanation, the concentration of K necessary to restore pulsations is increased tremendously over the optimum physiological K-concentration. The lethal K-dosage for such irradiated hearts is also greater than for the untreated organ. These results lead the author to conclude that α- and β-radiations have antagonistic effects.—*H. Grundfest.*

1135. PURJESZ, B., E. v. ROSZTOCZY, und E. v. CSINADY. Sportärztliche Untersuchungen. I. Untersuchungen über die Schwankungen der Herzgrösse, der Pulsfrequenz, der Zahl der Atemzüge und des Blutdruckes. *Arbeitsphysiologie* 3(7): 558-563. 1930.—Measurements were made on 54 subjects of the body weight, height, breadth and circumference of thorax, sitting height, body surface, musculature, and various indices. Four groups were studied, a control group consisting of medical students, members of sport associations, and students in military service; a group of soldiers; a group of trained and untrained swimmers, and a group participating in 3 classes of athletics, such as fencing, wrestling and football and rowing. The transverse diameter of the heart was measured and the increase and return to the rest level of the pulse rate, respiration rate and blood pressure after 30 deep knee bendings. The more trained the individuals were, the less was the reaction to the knee bending, and the earlier was the recovery to the rest level. The transverse diameter of the heart increased in proportion to the intensity of the sport, although within narrow limits. Long continued training resulted in a lowering of the frequency of the pulse and respiration.—*T. M. Carpenter.*

1136. STRAUSS, H. Über die Wirkung der Ermüdung auf den normalen und gesteigerten Blutdruck. *Zeitschr. Ges. Physikal. Therap.* 39(4): 203-206. 1930.—In 27 normal persons and 15 with hypertonia the blood-pressure was taken before and for 5 min. after the 1st exertion test, a rapid ascent of 54 steps; then a "fatigue test" was made either by a slow ascent of steps, by a walk, by standing at attention for 20 min., or by some other means of fatigue. Then followed a repetition of the 1st exertion test. In the normal subjects the 1st exertion test was followed by a rise in blood-pressure, which after 2-4 min. sank to the original value. After the fatigue test the blood-pressure rose, but not so high as after the 1st test; the base as well as the peak of the curve was lower than after the 1st test. Weak persons, however, sometimes showed a fall instead of a rise. The hypertonics showed after the 1st exertion test a greater rise than the normals; the blood-pressure fell to its original value after 4-6 min. After the fatigue test there was no fall as in the normal subjects; and after the 2nd exertion test the rise was as high as after the 1st; sometimes there was a secondary rise which made the peak of the 2nd curve higher than the 1st.

1137. TAYLOR, N. B. The relation of temperature to the heart rate of the South African frog (Xenopus dactylethra). *Jour. Physiol.* 71(2): 156-168. 1931.—Observations on the excised heart of the common frog confirm the statement that the sinus rate bears a roughly linear relation to the temp. when the tests are carried out in summer. Since the hearts of English frogs cease to beat at a temp. much higher than 22° C. or lower than 4° C., about 50 hearts of South African frogs were used to ascertain whether the linear form of the temp. frequency curve would be maintained over a wider range. Data were obtained over a range of 35° C. or more, i.e.,

nearly double the range possible with the English species; the heart functions, however, were scarcely normal toward the upper limits of the range. The linear relation of sinus rate to temp. was maintained by the heart of the South African frog up to about 27° C., beyond which was a slight slowing, the cause of which is obscure, followed at about 33° C. by a sudden and great acceleration apparently resulting from a "circus movement." Results indicate that in the intact South African frog there are usually 2 summits on the curve relating the heart rate to the temp. The 1st is at about 12-14° C., the 2nd at about 25° C. The heart of the South African frog is subject to vagal tone at temp. which are neither very high nor very low—a fact which may in part account for the drop in pulse rate between 12 and 16° C.—a phenomenon which is not noticed in the British frog in which vagus tone appears to be absent.

1138. THÖRNER, WALTER. Trainingsversuche an Hunden. I. Der Einfluss der Laufarbeit auf das Herz. *Arbeitsphysiologie* 3(1/2): 1-26. 6 fig. 1930.—Dogs were caused to run daily throughout 3½ and 4½ mos. long periods on a treadmill. They covered 1808 to 3170 kilometers. The performance gradually automatically increased throughout the period of training. Control dogs were studied. The trained dogs lost 6 to 7% of body weight whereas the control dogs gained. The heart shadows became enlarged in all the dogs, but whereas in the control dogs all dimensions were increased, in the trained dogs, the long diameter was increased more than the others. The electrocardiogram showed that the heart frequency was diminished in the trained dogs as compared to the control as 94 to 145. The heart pause was lengthened and the time for the contraction of the auricle plus conduction was less than the ventricular time. The curves showed a decrease with the trained dogs of the auricular wave, increase of the *t* wave and a diminution of the *s* wave. The majority of these signs are recognized as symptoms of vagus stimulation and lead to the assumption of a vagotonic conditioned dilatation with a tendency to eject a greater quantity of blood. All the findings lead to the assumption of a simultaneously existing hypertrophy of the heart muscle which was completely confirmed by autopsy. The trained dogs had heavier hearts in relation to other parts of the body. The hearts of the trained dogs were 0.87% of the body weight as compared with 0.68 in the control dogs. The skeletal musculature of the trained dogs was 39.5% of the body weight as compared to 31.1% in the control dogs. Not only had the heart increased in the work dogs, but in a greater proportion than the skeletal musculature so that the heart-musculature ratio was greater in the trained dogs than in the untrained dogs. The hearts of the trained dogs contained 33.32% fat as compared with 25.22% in the control dogs. All of the findings both clinical and autopsy pointed to a heart increased in size which resulted from an active vagus influence and increase in actual musculature.—*T. M. Carpenter.*

1139. TSO, T. M. The effect of variations in the diastolic filling of the frog's ventricle upon the durations of the refractory period and the mechanical response. *Jour. Physiol.* 68(4): 441-453. 8 fig. 1930.—Pairs of break shocks with varying frequency and intervals were used as stimuli on the isolated ventricle of *Rana temporaria*. There was no detectable change in the absolute refractory period (A.R.P.) and the relative refractory period (R.R.P.) of the isolated frog's ventricle studied by variations in diastolic filling. Variations from 0.01 to 0.07 c.c. respectively were considered. It is now known that the apparent latent period is greater with small filling than with large filling. With consideration of the apparent latent period in the contractile process, there is no detectable change in duration of the mechanical response of ventricle with fillings varying from 0.01 to 0.08 c.c.; but if the latent period be deducted from the measurements obtained, then there is an observable increase in the duration of the contractile process whch is in accordance with the results of other investigators (Segall and Anrep). Here, the angle is indicative of the end of the systolic plateau or contractile process which appears 0.01 sec. after the end of the A.R.P. when moderate fillings are used.—*D. J. Verda.*

1140. WESTENBRINK, H. G. K., et PH. ARONS. Recherches chimiques sur l'automatine. I. *Arch. Néerland. Phys. Homme et Animaux* (*Sér. 3C des Arch. Néerland. Sci. Exactes et Nat.*) 14(3): 394-406. 2 fig. 1929.—Zwaardemaker has stated that the heart whose contraction has stopped by keeping on Ringer solution without K can contract again under the influence of radium emanations. The authors have studied the mechanism of this activation and conclude that it is due to liberation of "automatin." This "automatin" is soluble in water and alcohol; is dialyzable through a collodion membrane; is not destroyed by HCl or nitrous acid (reagents which destroy adrenalin); is not destroyed by boiling NaOH; is not precipitated by $AgNO_3$ (which precipitates histamine) and is not adsorbed by kaolin.—*E. S. G. Barron.*

1141. WIGGERS, CARL J., HAROLD THEISEN, and HARLEY A. WILLIAMS. Further observations on experimental aortic insufficiency. II. Cinematographic studies of changes in ventricular size and in left ventricular discharge. *Jour. Clin. Investigation* 9(2): 215-233. 1 fig. 1930.—The changes in ventricular areas before and after production of an experimental aortic insufficiency were [in a large number of experiments on 10 dogs] studied at constant heart rates, for the purpose of evaluating the percentile regurgitation. Successive photographs of the exposed heart, properly suspended in the pericardium, were taken at intervals of 0.031 sec. by means of a moving picture camera. Each photograph was subsequently projected, its outline drawn and the area measured. The values so obtained were plotted as curves and related to simultaneous records of aortic pressures and anteroposterior movements of the left ventricle. The advantages of the method and the precautions necessary in its employment are analyzed in detail. The curves of outline changes during systole and diastole resemble volume curves in their general characteristics, but do not permit us to draw direct conclusions as to the degree to which the stroke of the left ventricle increases during aortic insufficiency. This is accomplished by applying Skavlem's formula, determining the increase in output and adding this to ½ the output of the 2 ventricles. By taking the left ventricular discharge, so determined, as a base, the percentile increase in stroke volume is easily calculated. The results show that during aortic insufficiency the diastolic size is larger and the left ventricular discharge is increased from 16-58% in different experiments, on an average 36.4%. Factors other than heart rate and size of leak are responsible for the variations. In the discussion it is pointed out (a) that changes in heart size without data concerning the stroke volumes of the left ventricle are of no value in determining the percentile regurgitation, but (b) that the percentile changes in stroke volume of the left ventricle give by inference a fair estimate of the percentile regurgitation. The conclusion is reached that approximately ⅓ of the discharge during systole regurgitates through insufficient valves during diastole.—*Authors' summary.*

1142. **ABDERHALDEN, EMIL, und SEVERIAN BUADZE. Untersuchungen über die Herkunft des Kreatins bzw. Kreatinins im tierischen Organismus.** *Zeitschr. Ges. Exp. Med.* 65(1/2): 1-26. 1929.—The influence of the intraven. or oral administration of a series of compounds on creatine and creatinine production was noted in dogs and pigeons. The administration of adenine and guanine resulted in a significant increase in the total creatinine; a synthesis of methyl guanidine acetate from these purine bases doubtless occurs. Thyroxin markedly increases the creatine and creatinine output after guanine. The administration of nucleic acids gave an increase in creatine and creatinine, but the activity of the liver and spleen complicate the results noted. The increased output was apparent only and insignificant. Uric acid was not concerned in the production of creatine. The influence of various organs (spleen, liver) on the creatine and creatinine production was noted. These organs can produce creatine from purine bases as well as from nucleic acids. However, exclusive of muscle, the quantities formed by other structures are small. No single organ studied, synthesized creatine from histidine. A significant increase in the total creatinine (creatine and creatinine) was observed following administration of arginine, sarcosin, guanine, adenine, histidine and n-methyl hydantoin. No change was observed after the administration of nucleic acids, uraci or mono-sodium urate.—*O. W. Barlow.*

Pharmakol.* 139(5/6): 353-356. 1928.—The acetonyl barbiturie acids, into which noctal and pernocton are first demonstrably converted in the organism, and also the corresponding malonyl-ureido-acetic acids, further products from these hypnotics and from the acetonyl compounds, are practically non-toxic to rabbits in doses of 0.25 to 0.5 gm. per kgm. intraven.—*E. V. Lynn.*

1145. **BOEDECKER, FR., und H. LUDWIG. Über Noctal und Pernocton. IV. Wertbestimmung ähnlicher im Bromallylrest abgewandelter Barbitursäuren.** *Arch. Exp. Pathol. u. Pharmakol.* 139(5/6): 357-360. 1 fig. 1928.—The method used, which gives very uniform results with noctal, consists of determining the time during which carefully selected animals remain lying on their sides when so placed. The γ-bromallyl, the β-chlorallyl, and the β-γ-dibromallyl derivatives of isopropylbarbituric acid, and the di(β-bromallyl) and di(β-chlorallyl) derivatives of barbituric acid were all found to be highly active, thus confirming the supposition that unsaturated halogenated groups are important in synthesis of hypnotics of this class.—*E. V. Lynn.*

1146. **BOEMINGHAUS, H., und M. KOCHMANN. Über quantitative Unterschiede in der Wirkung der Lokalanästhetika auf sensible und motorische Nerven. (Ein Beitrag zur Frage der Leitungsanästhesie.)** *Arch. Exp. Path. u. Pharmakol.* 141(3/4): 237-245. 1929.—The aims of the research were: (1) to study the difference in the sensitiveness of the motor and sensory nerves, and (2) to compare the action of various local anesthetics (cocaine, tropacocaine, tutocaine, psicaine, novocaine, eucaine, stovaine, K_2SO_4, and 2 new preparations, "C 147" and "1112"). Sensory nerve preparations and nerve muscle preparations of the ♂ frog were used; the dose of a given anesthetic which would inhibit a given stimulus in one set of nerves was compared, in 12 and 24-hr. studies, with that which would inhibit the same stimulus in the other set of nerves. The sensory nerve stimuli were inhibited by weaker concentrations than the stimuli to the motor nerves, except in the case of "1112" and stovaine, in which no such difference was to be observed. For given concentration of the various anesthetics differences in the reaction time were observed, cocaine working most rapidly, psicaine most slowly. The difference in time of response between sensory and motor nerves was not great; but in general the motor nerves were paralyzed. Stovaine again constituted an exception, paralyzing the motor before the sensory nerve—an observation from which Santesson had drawn a general conclusion as to the relation of these 2 sets of nerves. —*From authors' summary (transl.).*

1147. **BORNSTEIN, A., und GÜNTHER BUDELMANN. Die Ausscheidung von Alkohol und Äther durch die Niere.** *Arch. Exp. Path. u. Pharmakol.* 150(1/2): 47-69. 1930.—The in situ human kidney excreted alcohol in the urine at about 1½ times the concentration that it occurred in the blood. Therefore, the kidney has the power to concentrate it. The Starling heart-lung kidney preparation also concentrated alcohol easily, as well as ethyl ether, methyl alcohol, and acetone. A part of this concentration is purely physico-chemical since the concentration of alcohol and similar substances is higher in the perfusion fluid that enters the kidney glomerulus than it is in the whole serum. The concentration of alcohol was somewhat less in an artificially perfused kidney than in the perfusion fluid. The greatest dilution occurred in the glomerular filtrate. The results are explained by a modification of Höber's theory of concentration of lipid substances in the tubule epithelium.

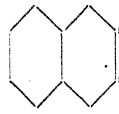
1156. **EISLER, B., und A. SCHITTENHELM. Über die Wirkung des Thyroxins auf den Blutjodgehalt des Myxödematösen.** *Zeitschr. Ges. Exp. Med.* 68(1/4): 487-492. 3 fig. 1929.—The I content of blood, markedly subnormal in myxedema, was raised by thyroxin, at first to supranormal values, followed by gradual sinking to about normal values despite continued administration of thyroxin. In normal subjects thyroxin, even with continued administration, has no effect on blood I level. In myxedema there is no parallelism between the increase in basal metabolism and blood I provoked by thyroxin; indeed there is the difference that unlike blood I, basal metabolism continues to increase during continued thyroxin administration. Intraven. and oral administration of thyroxin in myxedema have the same effect on blood I.

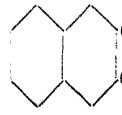
1157. **ENGELHART, E., und O. LOEWI. Fermentative Azetylcholinspaltung im Blut und ihre Hemmung durch Physostigmin.** *Arch. Exp. Pathol. u. Pharmakol.* 150 (1/2): 1-13. 10 fig. 1930.—Physostigmine inhibited the splitting of acetylcholine by whole blood, plasma, erythrocytes, and ghost cells. As dilute solutions as 1: 40 million were active. Other alkaloids, such as morphine and strychnine, did not present this inhibiting property. Physostigmine also acted to inhibit enzymatic splitting of acetylcholine adsorbed on charcoal. Heating to 58° C. did not inactivate the enzyme of human blood, but did that of cows' blood. Dry human blood split acetylcholine at 38° C., but did not at 58° C. Fluorescent light did not injure the acetylcholine-splitting of either fresh or dried human or cows' blood: dry serum, inactivated by heat, prevented the inactivation of fluorescent light on the esterase of yeast extract. The acetylcholine-splitting enzyme proved to be a glycerol-soluble esterase.

1158. **EULER, ULF VON. Zur Kenntnis des Antagonismus zwischen Adrenalin und Ergotamin.** *Arch. Exp. Pathol. und Pharmakol.* 139(5/6): 375-377. 1929.—Ergotamine lowers the body temp. of the febrile and normal rat and rabbit by diminution of chemical heat production and paralysis of the sympathetic part of the heat centers. The rate of oxidation (frog's muscles in small pieces) is increased by small concentrations and diminished by alcoholic or colloidal solutions of ergotamine. Epinephrine, also, speeds oxidation, an effect which is offset by equal doses of ergotamine.—*H. Graf.*

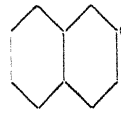
1159. **FENWICK, FLORENCE, and ELIZABETH GILMAN. The use of the antimony-antimony trioxide electrode for determining the dissociation constants of certain local anesthetics and related compounds.** *Jour. Biol. Chem.* 84(2): 605-628. 3 fig. 1929.—Acidity determinations have been made at 25° with the $Sb-Sb_2O_3$ electrode on a series of solutions of 4 new local anesthetics of the naphthalene series (A). Hydrochloride of 2-ethoxy-3-diethylaminopropylnaphthoate



(B). Hydrochloride of 2-ethoxy-3-dibutylaminopropylnaphthoate

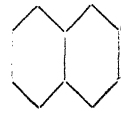


(C). Hydrochloride of diethylaminoethyl-β-naphthoate



; and

(D). Hydrochloride of 2-ethoxy-3-diethylaminoethylnaphthoate



together with procaine, diethylaminoethanol, and aniline hydrochloride. From these sets of values the corresponding basic dissociation constant was computed by an extrapolation involving the Debye-Hückel equation for the activity coefficient of an ion at vanishing concentration. This constant was compared in each case with the apparent dissociation constants calculated for the several dilutions measured. The order of increasing basicity of the 4 related anesthetics proved to be the same as the order of increasing anesthetic efficiency. The relationship between the order of increasing basicity and the chemical structure of the members of the naphthalene series was found to be the same as that discovered for the procaine series by Vliet and Adams. Comparison measurements made with the Sb and H electrodes on solutions of the compounds named and also benzoic acid and *p*-aminobenzoic acid failed to agree; the behavior of the H electrode is shown to be erratic and untrustworthy.—*Authors' summary.*

1161. **FRIEDMANN, L. Über den Einfluss kleiner Jodkalimengen auf den erhöhten Blutdruck.** *Deutsches Arch. Klin. Med.* 165(3/4): 243-244. 1929.—Doses of 5 cc. of a 2.5% KI solution were administered orally to each of 25 patients (52 doses were given in all), and blood-pressure was taken covering periods of 10 to 20 min. Of the 52 curves 20 showed no effect on the blood-pressure; 14 (mostly cases betraying signs of damaged kidneys) showed rather sharp rises in blood-pressure, ranging from 15 to 55 mm. Hg and averaging about 30 to 40 mm. Hg; while 18 (chiefly cases of relatively benign hypertension, with initial pressure between 170 and 190 mm. Hg and normal urine) showed falls in pressure, beginning ½ hr. after administration of KI and reaching the lowest point (averaging 15 mm. fall) about 1 hr. after dosage.

1162. FUSS, H. Über Störungen des Kohlenhydrathaushalts bei der Narkose. I. Mitteilung. Der Blutmilchsäurespiegel bei der Äthernarkose des Hundes. *Zeitschr. Ges. Exp. Med.* 72(5/6): 313-336. 4 fig. 1930.—The following conclusions are drawn from 29 exps. on an unspecified number of healthy dogs. Under ether drop narcosis a very prompt rise in lactic acid occurred in the dog's blood, and continued to the end of narcosis, even when this lasted for 3 hrs.; after discontinuance of the ether the rise in lactic acid ceased within 1-2 hrs., in many cases being followed by subnormal lactic acid values. Normally there are very slight differences between the blood lactic acid of the femoral vein and the femoral artery; no significant alteration of the difference was observed during narcosis. No material differences were observed during narcosis between the lactic acid content of the portal and the hepatic vein. The blood lactic acid rose more rapidly and to a higher point during ether narcosis and sank more rapidly afterward, than the blood sugar; thus there was no constant ratio between blood lactic acid and blood sugar during narcosis. During inhalation ether narcosis (ether mixed with pure O), however, unlike ether drop narcosis, lactic acid formation in the dog's blood was very limited, even when the narcosis lasted for 3 hrs.; but immediately after discontinuance of the O-ether mixture the blood lactic acid rose to a point comparable to that attained under ether drop narcosis. Several hrs. after end of narcosis (even 24 hrs. after) it frequently was subnormal. In 1 exp. the postnarcotic rise in lactic acid was reduced by continuation of O-inhalation after discontinuance of the ether. Muscular effort produced rise in blood lactic acid only when very strenuous; the rise even then was less than that produced by narcosis, and fell back to normal in ½ hr. Hence it seems unjustified to attribute to restraint and excitement the rise in blood lactic acid accompanying narcosis. It is concluded that the rise of blood lactic acid narcosis is due, not to any local, but to a general, disturbance of lactic acid metabolism; and not to any augmentation of the 1st or anaerobic phase of carbohydrate metabolism (in which the carbohydrate is split up with formation of lactic acid) but to a protraction of the 2nd, or aerobic phase (in which the lactic acid under the influence of O is resynthesized to glycogen). The ether-O inhalation experiments showed that the diminution of oxidation processes is a mere by-occurrence and not an essential feature of the narcosis.

1164. GARELLO, ALBERTO. Sull'azione farmacologica delle resine colloidali di Incenso, Mirra, Guaiaco. [On the pharmacologic action of the colloidal resins of incense, myrrh and guaiac.] *Atti Soc. Ligustica Sci. e Lett.* 8 (4): 279-290. 1929.—It is easy to prepare from the resins of incense, myrrh or guaiac, colloidal substances which are suitable for pharmacologic study. Myrrh and guaiac are non-toxic, while incense is somewhat toxic. When the latter is applied to the isolated heart it causes arrest in diastole. No action was noted on blood-pressure or on the conductivity of nerves and muscles.—*A. Garello (transl. by H. C. Wood).*

1165. GARELLO, ALBERTO. Sulla tossicatà del decotto acquoso di resina di guaiaco in confronto colla stessa resina colloidale. [The toxicity of the aqueous decoction of the resin of guaiac as compared with the colloidal form.] *Atti Soc. Ligustica Sci. e Lett.* 8(4): 291-297. 1 fig. 1929.—There is a difference in the effects on fermentation, sprouting, heart-action and blood-pressure, between the aqueous sol. of guaiac and the colloidal form, due to a small amount of saponin which is present in the decoction but not in the colloidal resin.—*A. Garello (transl. by H. C. Wood).*

1166. GESSNER, OTTO. Über die Darmwirkung von Rivanol, Yatren und Emetin. *Arch. Schiffs- u. Trop.-Hyg.* 33(5): 277-281. 1929.—The pharmacologic action of "rivanol," emetine and yatren was studied on the isolated intestine of frogs, guinea pigs and rats. Rivanol in weak and medium concentrations caused an increase in the tonus of the frog intestine, in high concentration, irreparable contraction. In intestine of guinea pig and rats rivanol in concentration of 1: 1,000,000 and 1: 100,000 sometimes even in 1: 10,000 increased the tonus considerably. After rivanol of 1: 100,000, 1: 10,000 and especially 1: 1000 a paralyzing action occurred which in contrast to the effect of papaverine and yatren was not reversible. Emetine caused a strong excitation in concentrations of 1: 1,000,000 and 1: 100,000. In concentration of 1: 10,000 and 1: 1000 a reversible paralyzing action on the intestine of the frog was obtained. In guinea pigs and rats the paralyzing action was obtained in concentrations of 1: 100,000 and even 1: 1,000,000. Yatren stimulated in all concentrations up to 1: 100. Paralyzing action was only obtained at 1: 100 or even 1: 20. The Ba reaction of the intestine remained. Often the rat's intestine was not paralyzed by yatren 1: 20 (5%). The paralyzing action of yatren was reversible, demonstrating comparatively low toxicity. The exciting action of yatren can be eliminated by the addition of uzara (uzarin 1: 100,000), which should be used where yatren causes diarrhea. Rivanol is 200 times as poisonous as yatren. Sunlight increases the toxicity of rivanol but not of yatren.—*F. R. Greenbaum.*

1167. GOLD, HARRY, and ARTHUR C. DeGRAFF. Studies on digitalis in ambulatory cardiac patients. II. The elimination of digitalis in man. *Jour. Clin. Investigation* 6(4): 613-626. 1929.—The curve of digitalis elimination, in terms of persistence of action, was successfully studied on 23 patients afflicted with auricular fibrillation. Reduction in heart rate was the index of action employed. It was shown that a certain percentage, and not a fixed amount, of the drug was eliminated daily under the given conditions. The percentage excreted varied with the amount present in the body at any time. In essentials, man does not differ from other animals in the elimination of digitalis.—*M. Dresbach.*

1168. GRODINSKY, MANUEL, and R. RUSSELL BEST. Sacral anesthesia. An experimental and clinical study. *Jour. Urol.* 22(2): 187-212. 2 pl. 1929.—An epidural injection of 20 cc. of novocaine sol. is sufficient to anesthetize the 5th sacral nerve completely and the 4th (sometimes the 3rd) less completely. A 30 cc. injection anesthetizes them completely. A 40 cc. injection anesthetizes the 5th, 4th, and 3rd nerves completely and the 2nd and 1st less completely. In order to anesthetize completely the 1st 2 sacral nerves, it is necessary to use volumes greater than 40 cc. (50 to 75 cc.) or to combine a smaller caudal injection (30 to 40 cc.) with transacral injection of the upper 2 sacral foramina. Since volumes greater than 40 cc. are apt to reach high levels about the cervical cord and medulla, the combined method is preferable where it is necessary to anesthetize the first 2 sacral nerves. In our experience, weaker solutions of novocaine (1% or even less) are almost if not as effective as the stronger solutions (2% or more) and are to be preferred. The presence of excessive perineural fat and connective tissue makes it difficult for aqueous solutions of dye or novocaine to reach the bare nerves and suggests the use of some more penetrating anesthetic solution.—*Authors' conclusions.*

1169. GROSS, R., und J. WADEL. Studien zur Kohletherapie. I. Mitteilung. Veränderungen im Blute bei Tuberkulösen. *Beitr. Klin. Tuberk.* 74(5/6): 613-628. 8 fig. 1930.—The intraven. injection of ¼ to ½ cc. of finely divided carbon in suspension results in an increase of circulating lymphocytes and monocytes in normal man. The same result may be observed in tuberculous individuals if the injection influences the disease favorably. It is presumed that the treatment stimulates the reticuloendothelial system. An initial dose of ¼ cc. is suggested, to be repeated at intervals of 10 to 14 days.—*Authors' summary (transl. by M. I. Smith).*

1170. HAENDEL, MARCEL, und JUAN MALET. Beiträge zur Pharmakologie des retikuloendothelialen Systems. IV. Wirkung verschiedener Faktoren. *Zeitschr. Ges. Exp. Med.* 67(3/4): 315-318. 1929.—In exps. on 12 guinea-pigs, with regard to the India ink storage capacity of the organs of the reticulo-endothelial system, the effect of drugs acting on the parasympathetic system was not very clear; atropine stimulated the reticulo-endothelial system and eserine stimulated it in one case and paralyzed it in another; the neurotropic drugs pantopon and barbituric acid had opposite effects: the first increased and the latter decreased the ink storage; novasurol and neosalvarsan produced an inhibition by poisoning of the reticulo-endothelial system; choleretic drugs stimulated it; glycerin caused a blockade of high degree; and hypertonic glucose solution had no clear effect.

1171. HANZLIK, P. J., and D. A. WOOD. The mechanism of digitalis-emesis in pigeons. *Jour. Pharmacol. & Exp. Therap.* 37(1): 67-100. 1929.—Digitalis emesis in pigeons is entirely prevented by vagotomy, and therefore must have a peripheral origin. Atropine and ergotoxine do not prevent emesis, indicating that the effect is mediated through the afferent vagus fibers and is reflex in nature. The heart, however, is not essential as was supposed by Hatcher and his associates, for typical emesis occurs after recovery from section of all cardiac branches of the vagus nerve. This leaves the abdominal viscera as the site of action of digitalis in producing emesis. Injection into other birds of extracts made from the heart and abdominal organs showed that the highest concentration of digitalis occurs in the liver, pointing to it as the most probable site of action. It is concluded that the emetic action is predominately a vagus reflex mediated through the local irritant action of the digitalis concentrated in the liver, and possibly other abdominal organs.—*McK. Cattell.*

1172. HARMON, PAUL M., and C. M. McFALL. The action of strychnine upon the denervated heart and upon the secretion of adrenin. *Jour. Pharmacol. & Exp. Ther.* 37(2): 131-146. 1929.—Strychnine sulphate, injected intravenously, in doses of 0.15 to 0.3 mgm. per kgm., has little effect upon the denervated heart of the cat. If the heart rate is increased above the average for the denervated heart, strychnine in the above doses has a primary depressant action, as shown by a sharp and brief decrease in the heart rate. With the denervated heart as an indicator no evidence was obtained that strychnine directly increases the output of adrenin. A convulsion or struggle after a strychnine injection usually temporarily increases the output of adrenin but since struggle causes the same effect equally well before the injection this cannot be considered a strychnine effect.—*Authors' summary.*

1173. HASHIMOTO, HIROSHI, und SHICHIZO KATO. Über den Einfluss des Cholins auf Seidenraupen. [Japanese.] *Kumamoto Igaku Kwai Zasshi* 3: 397-402. 1927.—One hundred silkworms (Bombyx Mori L.) were fed with choline throughout the whole life cycle. This was carried out by smearing the mulberry leaves with choline sol. The worms so fed ate the leaves more avidly and their lives were more prolonged than the control animals. Life was extended even into the second generation. The body weight increased significantly in both generations, but the length of body in the second was shorter than in the first.—*Author (courtesy Japanese Jour. Med. Sci. IV) (transl. by E. V. Lynn).*

1174. HAYAMA, TSUNEMICHI. Pharmakologische Reaktionen der Taubenpupille, nebst ihren vergleichenden Studien mit denen der Säugetierpupille. [Japanese.] *Nihon Gankwa Gakkwai Zasshi* 31: 607-619. 1927.—The dilation of the pigeon's pupil after instillation of various drugs was investigated. Tetrodotoxin, atropine, homatropine and cocaine gave only mydriasis; physostigmine and veratrine gave only myosis; while drugs of the digitalis group produced a small myosis which soon gave place to a persistent, intense, mydriasis. Epinephrine, pilocarpine, arecoline, choline, guanidine, quinine, Ba, Ca, K, and Mg had no effect. It is noted that the pigeon's pupil reacts in general more weakly to nerve poisons, more strongly to muscle poisons than does the pupil of mammals.—*Author (courtesy Japanese Jour. Med. Sci. IV Pharmakol.) (transl. by E. V. Lynn).*

1175. HEYMANS, M. C., et M. L. REMOUCHAMPS. Contributions à la pharmacodynamie et à la physiologie du coeur. Action centrale et réflexe de l'adrénaline et de la pression circulatoire sur la fréquence du coeur. *Rec. Mém. Couronnés et Autres Mém. Acad. Roy. Méd. Belgique* 23: 7-33. 31 fig. 1927.—Epinephrine is not a direct stimulant to the cardioinhibitory (vagus) center. Rise in pressure limited to the cephalic blood vessels is capable of slowing the heart through stimulation of the vagus center. Partial anemia or partial asphyxia of the head and rise in pressure within the blood vessels of the trunk sensitize the vagus center to changes in pressure in the cephalic blood vessels. The response of the vagus center to rise in pressure in the cephalic blood vessels is diminished or abolished, through reflexes, by reduction of pressure within the blood vessels of the trunk. Stimulants of the vagus center, such as nicotine, veratrine, lobeline, acetylcholine, slow the heart through a central action, in spite of fall in pressure in the vessels of the trunk. Stimulation of the carotid sinus causes a reflex fall in blood pressure and slowing in heart rate. Removal of the cerebral hemispheres, section of the trigeminal, glosso-pharyngeal, and hypoglossal nerves, do not prevent the bradycardia consequent upon rise in pressure within the cephalic vessels alone. The vagus center still responds to changes in cephalic blood pressure. Rise in pressure limited to the blood vessels of the trunk slows the heart through a vagus reflex. While fall in pressure within the blood vessels of the trunk markedly reduces the response of the vagus center to changes in pressure in the cephalic vessels, fall in pressure in the cephalic vessels, on the contrary, diminishes only very slightly the reflex bradycardia consequent upon rise in pressure in the vessels of the trunk. The regulation of heart rate in accordance with changes in blood pressure (law of Marey) is therefore both cephalic and somatic in origin. The somatic reflex is always the predominant mechanism.—*Authors' abstract (transl. by C. F. Schmidt).*

1176. HOFFMANN, W. H., y VICENTE A. EMBIL. Observaciones sobre unos casos de ciguatera. *Rev. Med. y Cir. Habana* 33(18): 884. 1928.—Poisoning by fish, *Sphyraena picuda* B., was observed in Central and So. America, especially in Cuba and the lands bordering Caribbean sea in 1926. Symptoms observed in 23 cases were: vomiting, diarrhea, abdominal pain, cramp, weakness, small, slow and compressible pulse, and general depression. Several other cases in men and animals are cited. Experiments carried out by feeding it to dogs and cats failed to produce poisoning or intoxication. It is concluded that ciguatera or poisoning by such fishes, in the fresh state, is a definite disease; different from Ichthyotoxismus or poisoning caused by ingestion of decayed fishes; or that produced by venomous fishes.—*F. Garcia.*

1177. HÖGLUND, GUSTAF. Experimentelle Studien über die Wirkung des β-tetrahydronaphtylamins auf das weisse Blutbild von Kaninchen. *Acta Med. Scandinavica* 70(5/6): 571-589. 1929.—Injection of β-tetrahydronaphthylamine in a dose of 0.01 to 0.04 gm. per kgm. produces in rabbits a significant increase of the total white blood corpuscles in blood from veins of the ear, the increase depending upon rise of the neutrophil leucocytes. Even in animals deprived of their central heat-regulation by a complete severance of the nerve trunk, there occurred a similar increase. Arterial leucocytosis was much less marked. Accordingly, it depended, at least in great part, upon a displacement of the neutrophil leucocytes toward the peripheral part of the vascular system.—*Author's summary (transl. by E. V. Lynn).*

1178. HOLTEN, CAI. Additional investigation into the effect of insulin on the respiratory metabolism.

Acta Med. Scandinavica 71(3/4): 285-300. 1929.—The respiratory quotient rises twice as much in normals as in diabetics, the average change being in diabetics from 0.769 to 0.811, in normals from 0.843 to 0.920 (2 hrs. after insulin). In normals the heat production is not changed by insulin, while in diabetics the heat production is to some extent reduced. The explanation of these facts seems to be that in diabetics the quotient in the post-absorptive state and 14-24 hrs. after insulin is higher than that corresponding to the actual catabolic quotient owing to synthesis of fat from carbohydrate. This synthesis ceases after injection of insulin. In normals this synthesis does not take place. The rise of the quotient after insulin therefore is necessarily less in diabetics than in normals. The decrease in heat production after insulin in diabetics is probably connected with the cessation of the synthesis mentioned, as this causes a loss of energy.—*C. Holten.*

1179. **HUNT, REID. Promotion of medicine and pharmacy.** *Science* 72(1855): 49-58. 1930.—Presidential address at the 1930 U. S. Pharmacopeal Convention.

1180. **KARELITZ, SAMUEL, PHILIP COHEN, and SIDNEY D. LEADER. Insulin inactivation by human blood cells and plasma in vitro. Effect of normal and of diabetic blood on insulin action.** *Arch. Internal Med.* 45(4): 546-558. 1930.—The blood plasma of a diabetic child who did not respond properly to insulin inhibited the insulin action in rabbits. The same phenomenon occurred with blood from normal persons, young or old. A greater inhibition was caused by blood cells than by plasma. A still greater inhibition occurred when the cells were laked, which showed that the inhibiting substance is mainly endocellular, and to a less degree in the plasma. Greater inactivation is produced by blood from diabetic patients than results from blood of normal persons. Control experiments showed that this inactivation is not due to dilution, viscosity of the fluid, rate of absorption from under the skin or adsorption by the cells, or the pH of the blood for the period of incubation used in our experiments, not more than 2 hrs., except at pH 6 or lower when the inactivation ceases and at pH 9.2 when it is increased, most likely due to the alkali itself. The inhibition of the action of insulin by blood depends on the quantity of the active principle. That may explain why other authors who have used smaller amounts of blood similarly, obtained negative results. Furthermore, the inactivation may vary with different persons and with the same person at different times, perhaps even at different hrs. of the day, e.g., as related to meals, exercise, etc.—*Authors' summary.*

1181. **KATO, SEIGO. Über die Ausscheidung des intravenös injizierten Urotropins im Harn.** [Japanese.] *Rinsho Igaku* 15: 894-902. 1927.—In exps. with rabbits and men urotropin, intraven., can be found in urine as such 3-5 min. after injection. The excretion is particularly rapid during the 1st hr., the height being reached 20 min. after injection; then it slows down. Four to fifty hrs. after injection no urotropin can be detected in urine. If 5 cc. of 40% sol. are given intraven. to a man, 67-92% of the urotropin can be recovered from the urine in course of 24 hrs. after injection.—*Author (courtesy Japanese Jour. Med. Sci. IV. Pharmacol.) (transl. by B. Siaulis).*

1182. **KENDRICK, J. F. The treatment of hookworm disease with tetrachlorethylene.** *Amer. Jour. Trop. Med.* 9(6): 483-488. 1929.—Fifty-nine prisoners were treated with 3 cc. of tetrachlorethylene, 30 with 2 cc., and 30 with 2.4 cc. of a 3 to 1 mixture of tetrachlorethylene and oil of chenopodium. Subsequently the prisoners were treated until all worms were removed, and the efficiency rates were calculated on the basis of the % of worms recovered by the first treatment. When both hookworm species are considered, the efficiency rate for tetrachlorethylene alone, either in 2 or 3 cc. doses, is higher than for its mixture with chenopodium. Later, no fatalities and only 1 intoxication of significance were observed in a series of approximately 1,500 treatments with 3 cc. of tetrachlorethylene.—*N. R. Stoll.*

1183. **KERTI, F., und F. STENGEL. Über die Einwirkung von kurzfristiger O_2- und CO_2- Atmung auf das rote Blutbild beim Menschen unter normalen und pathologischen Verhältnissen.** *Wiener Arch. Inn. Med.* 16(2/3): 381-393. 1929.—This investigation was carried out on 45 individuals of both sexes and various ages. Besides the normal controls, patients with disturbances of the heart and circulation, diabetes, and diseases of the blood were utilized. The observations on the red blood cells included their number, diameter and hemoglobin contents. Following O inhalation in the 45 cases there was a definite decrease in the erythrocyte count in 16 cases, and an increase in 5 cases. Almost all cases showing a fall in the number of erythrocytes had originally a relatively high erythrocyte count. The hemoglobin contents and diameter of the red cells were little affected. Following CO_2 inhalations, the diameter of the red blood cells was but little affected except in the case of secondary polycythemia in which the microcytes decreased by one-half, and in a case of pernicious anemia in which the macrocytes were tripled in number. There was a definite increase in the number of erythrocytes in the normal cases. The same thing occurred in the case of pernicious anemia, while in 2 cases of secondary polycythemia and in 1 case of hypertension a fall of number occurred. In experiments with O the hemoglobin contents were little subject to change. No interpretation of the findings is offered, particularly since the results are not very uniform.—*G. Bachmann.*

1184. **KOCHMANN, M., und H. LYDING. Wirkung der Lokalanästhetika auf sensible und motorische Nerven in gepufferten Lösungen.** *Arch. Exp. Path. u. Pharmakol.* 141(3/4): 246-247. 1929.

1185. **KOCHMANN, M. Zur Pharmakologie der Expektorantien. Wirkung auf die Flimmerbewegung.** *Arch. Exp. Path. u. Pharmakol.* 150(1/2): 23-38. 1930.—Action of expectorants was tested on the ciliated epithelium of the frogs' pharynx, in vivo and in vitro. Rate of movement of small pieces of cork was measured after application of different drugs and ions. Some active expectorants increased the activity of the frogs' epithelium immediately—to this group belonged NaI, NH_4OH, NH_4Cl, emetine, and ethereal oils. Other active expectorants, such as apomorphine, did not increase the activity of the frogs' epithelium. The frog method cannot, therefore, be used to evaluate the worth of expectorants.

1186. **KOFLER, LUDWIG. Chemische, physikalische und biologische Eigenschaften der Saponine.** *Protoplasma* 7: 106-128. 1929.—A review, with an extensive bibliography.—*W. Seifriz.*

1187. **KOFLER, L., und R. FISCHER. Eine biologische Prüfung der Darmresorption von Kalkpräparaten.** *Arch. Exp. Path. u. Pharmakol.* 149(5/6): 326-335. 1930.—No simple method for testing and comparing the absorption of various Ca preparations has hitherto been known. White mice (number not stated) were given by mouth the Ca preparations to be tested, and after some time, a subc. dose of $MgSO_4$. If the Ca salt was absorbed, a larger dose of $MgSO_4$ was necessary to produce narcosis than in untreated animals; the increase in Mg dosage would be the measure of absorption. All Ca preparations tested were absorbed, with distinct differences between them in order of increasing absorbability they were: Ca glycero-phosphate, Ca lactate, $CaCl_2$, "Ca Sandoz," "kalzan," Ca lactate+saponin and $CaCl_2$+saponin.—*From authors' summary (transl.).*

1188. **KOPPÁNYI, THEODORE. Studies on pupillary reactions in tetrapods. VI. The mode of action of ergotamine.** *Jour. Pharmacol. & Exp. Ther.* 38(1): 101-111. 1930.—The technique of intraocular administration of drugs is described. Ergotamine tartrate instilled into the conjunctival sac, or injected intraocularly, produces maximal constriction of the pupil. This miosis is due to sympathetic paralysis, for faradic stimulation of the cephalic end of the cut cervical sympathetic nerve or the intravenous injection of epinephrine does not cause dilatation of the pupil previously constricted by ergot-

amine. The extreme miosis following ergotamine injection is made possible by sympathetic paralysis which allows the parasympathetic impulses to exert their full action. Ergotamine produces dilatation of the pupil—not constriction—due to sympathetic stimulation in the guinea pig. The fact that ergotamine produces paralysis of the sympathetic end organs in the dilator muscle of the cat's iris is utilized to study the action of cocaine and ephedrine, whose sympathomimetic nature has been questioned. The results indicate that these drugs do have sympathetic affinities.—*Author's summary.*

1189. **KOPPÁNYI, THEODORE. Studies on pupillary reactions in tetrapods. VII. Sympathetic actions of cocaine, procaine and pilocarpine.** *Jour. Pharmacol. & Exp. Ther.* 38(1): 113-119. 1930.—Massive doses of cocaine HCl injected intraocularly produce a dilatation, and then a constriction of the pupil. The pupil constricted by cocaine does not dilate upon faradization of the corresponding cervical sympathetic nerve, or upon the injection of epinephrine. This constriction, therefore, is due to sympathetic paralysis. Procaine HCl, in large doses, injected intraocularly, induces mydriasis which is not followed by miosis. Pilocarpine HCl in very small intraocular doses produces mydriasis and sensitizes the pupil to epinephrine and stimulation of the cervical sympathetic.—*Author's summary.*

1190. **KRISTENSON, ANDERS. Über das Verhalten von Elektro- und Mechanomyogrammen beim muskarin-(azetylcholinchlorhydrat- [sic]) vergifteten Froschherzen.** [Comparison between electrocardiograms and mechanocardiograms of frog hearts poisoned with muscarin.] *Skand. Arch. Physiol.* 54(5/6): 189-248. 11 fig. 1928.—Records were made of electrical and mechanical excursions in frog hearts perfused with muscarin solution to determine whether electrical and mechanical phenomena would be dissociated by muscarin as reported by Trendelenburg and Hoffmann. The dissociation was only apparent, and was obviated by a sensitive registration apparatus and very careful preparation of the heart. No electrogram without mechanogram.—*W. N. Berg.*

1191. **LABES, RICHARD. Über Kurarewirkung der Tellurite am Frosch.** *Arch. Exp. Path. u. Pharmakol.* 141(3/4): 142-147. 1929.—Out of a series of experiments on frogs carried on over several years, 6 are described. Small doses of K_2TeO produced complete paralysis of the hind legs and almost complete paralysis of the forelegs. During the progress of the paralysis of the hinder extremities indirect excitability through the sciatics was lost, while direct muscular excitability and sensibility of the limbs remained. This intoxication was therefore predominantly one of peripheral motor attack. This result was anticipated by previous work in which it was shown that K_2TeO does not attack ferments like salivary diastase until it has been reduced to elementary Te; and that the dehydrases concerned in tissue respiration in guinea-pig muscle were injured while the oxidases were not affected. Since, according to the views of many, the oxidases are most concerned in the respiration of the central nervous system, while the dehydrases are the most important factors in the respiration of most other organs, it was to be expected that K_2TeO intoxication would affect the respiratory processes more in other organs than in the central nervous system.

1192. **LAZAREW, N. W. Über die narkotische Wirkungskraft der Dämpfe der Chlorderivaten des Methans, des Äthans und des Äthylens.** *Arch. Exp. Path. u. Pharmakol.* 141(1/2): 19-24. 1929.—Taking the narcotic strength of $CHCl_3$ as 1, the following values were obtained by experiments on white mice (number not stated): CH_2Cl_2, 0.45; CCl_4, 0.55; CH_2Cl-CH_2Cl, 0.94; CH_3-$CHCl_2$, 0.52.

1193. **LEYKO, EMIL. The action of some heart tonics.** *Jour. Pharmacol. & Exp. Ther.* 38(1): 31-49. 1930.—Investigations have been performed with some new "heart-tonics" on the heart lung preparation, the diminution of the diastolic heart volume at constant output being the criterion of their tonic effect. Cardiazol has no influence on the heart tone. Coramine in small concentrations does not affect the heart-tone, in larger ones, such as 1: 25,000, it causes dilatation of the heart. Hexetone in weak solutions has also no effect on the tone of the isolated heart. In solutions 1: 25,000 it dilates the heart, and this effect like that caused by coramine is not influenced by atropine. As Na salicylate in such doses as are contained in the hexetone solutions only dilates the heart transitorily, the effect of hexetone may be due either to this substance alone or to both together. Cardiazol does not influence the coronary flow, coramine increases it, and hexetone and sodium salicylate diminish it transiently. Ephedrine and ephetonine produce a tonic effect. Their action is a little slower in onset, but more lasting as compared with that of adrenaline. The ratio of the doses of ephedrine and ephetonine to that of adrenaline in bringing about the same tonic effect on the same preparation is approximately 20: 1. Ephedrine and ephetonine like adrenaline increase the coronary flow, the relation of the doses required to produce a similar effect being the same as before.—*Author's summary and conclusions.*

1194. **LIGHT, ARTHUR B., and EDWARD G. TORRANCE. Opium addiction. VIII. The effects of intramuscular and intravenous administration of large doses of morphine to human addicts.** *Arch. Internal Med.* 44 (3): 376-394. 1929.—The pulse and respiration rates, electrocardiogram, blood chemistry and behavior of the addicts was noted following the administration of morphine sulphate by vein (6-9 times habitual dose) and by intramuscular injection (3-6 times habitual dosage). No significant changes were noted. Two patients (following an abstinence period of 48 hrs.) were injected with 11 and 20 grains of morphine by vein. No significant physiological or behavior changes were noticeable during the succeeding hr. Morphine disappears from the blood very rapidly following the injection of such dosages.—*O. W. Barlow.*

1195. **LOEPER, LESURE, et TONNET. L'influence de la thyroidectomie et de la thyroxinisation sur l'équilibre protéique du sérum.** *Progrès Méd.* 1929(33): 1381. 1929.—The authors had previously stressed the frequent rise of blood serum albumin from a normal 60% to 80% and more in Basedow's disease. Of 2 partially thyroidectomized patients ? was cured by the operation; the serum albumin in this case fell from 83% to 66%; the other patient was not improved; his serum albumin rose instead. In a totally thyroidectomized dog the serum albumin fell from 79% to 58%. In a dog of which ⅓ of the thyroid was removed the fall of serum albumin was only from 70% to 67%. The authors conclude that the return of the protein equilibrium to normal is a criterion of amelioration. Thyroxin (1 "mmgr." per day for 15 days) raised the serum albumin in a normal man from 65 to 77%, while leaving the total albumin unaffected. In a totally thyroidectomized dog the serum albumin had fallen to 58%; 1 "mmgr." of thyroxin a day for 15 days raised it to 65%. These results are believed to show the existence of a proteocrasic function in the thyroid gland.

1196. **McGUIRE, JOHNSON. Über Somnifen.** *Zeitschr. Ges. Exp. Med.* 71(3/4): 543-553. 3 fig. 1930.—From experiments on rabbits, cats and dogs (number not stated) and clinical observations, McGuire strongly advises against the use of somnifen for intravenous narcosis in experimental or therapeutic operations, because of its tendency to produce coagulation of the blood.

1197. **MACHT, DAVID I. A simple method of studying respiratory pharmaco-dynamics.** *Jour. Amer. Pharmaceut. Assoc.* 19(1): 7-11. 2 fig. 1930.

1198. **MARTIN, LAY, and JUSTINA H. HILL. I. The effects of mercurochrome and milk protein upon anaphylaxis.** *Bull. Johns Hopkins Hosp.* 46(3): 232-245. 1930.—Guinea-pigs were sensitized to egg albumin. At various intervals during the development of sensitization (taken as two weeks) different groups were injected with a varying number of doses of mercurochrome in-

traven. and milk protein intramuscularly and intraven. Each group was controlled with a similar or larger number of pigs. At the end of 2 weeks all the pigs were given the minimum effective dose which killed the majority of the control pigs. It was found that the agents listed above had the ability to protect a certain proportion of the test animals against death and very frequently against even light to moderate shock. To be effective the last desensitizing dose must not be given more than 24 hrs. before the shocking dose.—*L. Martin.*

1199. MASUDA, ROKUNOSUKE. Experimentelle Studien über die Kalkablagerung in der Haut. *Japanese Jour. Dermatol. and Urol.* 29(5): 423-455. (With German summary p. 33.) 2 pl. 1929.—For the experimental production of Ca deposition, 3 factors are necessary: a) Trauma, which causes a mild degree of degeneration of the muscles and connective tissue, b) Ca excess in the body, c) long duration of factors a) and b). Daily administration of 3 gm. of Ca lactate by mouth, or 2 cc. of a $CaCl_2$, 5%, intraven. for 41-50 days resulted in only a slight increase in the Ca content of the blood serum, and in a definite, constant increase in the Ca content of the skin and muscle tissues in the area which had been traumatized. These deposits were often grossly visible in the subc. tissues and in the fascial sheaths of the muscle layers. In some cases cartilage formation occurred. Following intragluteal injections of salts of heavy metals (Bi, Pb, Cu and Hg) deposits of Ca were frequently found in the liver, kidneys (in the epithelial cells of the convoluted and straight tubules) and in the muscles at the site of injection. The increase in the Ca content of these organs and of the blood serum as well, was not associated with any change in the Ca content of the skin and subc. tissues. No relation was found between the Ca content and the free fatty acid or lipid content of the tissues studied.—*Author's summary (transl. by M. A. Perlstein).*

1200. MATSUMORI, TSUNEO. The effect of adrenaline on the heart of the chick embryo. *Endocrinology* 13(6): 537-548. 1929.—Experiments with chick embryos have shown that adrenaline causes an increase in the frequency and contraction of heart preparations without regard to stage of development. Amount of acceleration varies with the stage of development, being weakest at the 61st to 70th hours of incubation and strongest at the 91st to 100th hours. The effect is always transitory. Heart strip preparations from the apex region react to adrenaline by decrease of frequency and height of contraction. The course of the reaction corresponds to that of heart preparations in general. Ventricular strip preparations are also stimulated by adrenaline. From the 5th to 7th day of incubation, however, a decrease in the frequency and an increase in the contractions is to be observed. With apex preparations a decreased frequency but an increased contraction occurs. The effect of adrenaline on the strip preparations is transitory, lasting at most only a few minutes. By and large, the effect of adrenaline on the embryonic heart is the same as that on the post-embryonic. Certain suggestions are made as to the point of attack of adrenaline.—*Author's conclusions.*

1201. MELVILLE, K. I., und R. L. STEHLE. Novasuroldiurese. *Arch. Exp. Pathol. & Pharmakol.* 123(3/4): 175-185. 1927.—Experiments on unanesthetized dogs with bladder fistula. Intravenous injection of 1 cc. novasurol caused slight primary slowing of urine flow for from 1 hr. 15 mins. to 2 hrs., followed by a marked diuresis lasting 2 hrs. Water and chlorides are chiefly increased; K/Na relationship being diminished: P first diminished, then increased. One experiment with anesthesia gave similar results. No glycosuria appeared at any time. Injection of novasurol into one renal artery, followed later by intravenous injection of grape-sugar solution, showed no marked differences in the compared urines collected from each side. The authors claim therefore that there is no immediate renal effect of novasurol. Either it must be changed into an active form, or its action is extra-renal. The authors incline towards the extra-renal action.—*O. S. Gibbs.*

1202. MESSINI, M. Azione del citrato trisodico sull'utero isolato. *Arch. Internat. Pharmacodynamie et Thérap.* 36(1): 1-16. 1929.—The uterus of the guinea-pig, whether virgin or gravid, reacts to trisodium citrate in proportions of 0.00015—0.00090%, with a marked increase of tonus; and to doses higher than 0.001% with a strong depression. Although it is not possible absolutely to exclude a decalcifying effect, the action is probably due to the anion directly rather than to any power of combining with calcium, admitting that the effect of the sodium, strongly stimulant in small doses and strongly depressant in large, masks the slight depressant action of the citric acid, which is probably a decalcification. The author does not assent to the conclusions of Sugimoto concerning the effects of sodium oxalate—that the primary stimulation and secondary depression of the uterus from increasing doses is due to variations in the amount of Ca subtracted.—*M. Messini (transl. by H. C. Wood).*

1203. MESSINI, M. Azione del glucosio sull'utero isolato. *Arch. Internat. Pharmacody. et Thérap.* 36(1): 17-25. 1929.—Very small doses of glucose, corresponding to that in Locke-Tyrode solution, exert a slightly excitant effect on the contractility of the uterus of the guinea-pig, either virgin or gravid. Large doses (2.45-4.9%) bring about an increase in the contractility of the gravid uterus with a marked increase of tonus. In the virgin uterus the same dose provokes a slight increase of tonus. The diversity of reaction of the pregnant and non-pregnant uterus to glucose, can harmonize the statements of Simonart—that glucose is an indifferent substance for the uterus—and the clinical results of Müller.—*M. Messini (transl. by H. C. Wood).*

1204. MESSINI, MARIANO. Sulla tossicità di alcuni sali di uranile. [Toxicity of certain salts of uranyl.] *Biochim. Terapia Sperim.* 16(4): 120-124. 1 fig. 1929.—The rapidly and slowly fatal dose of the sulphate, acetate and nitrate of uranyl was determined on rabbits, by intravenous injection. With the rapidly lethal dose the animals all died of respiratory failure, with the late fatal dose of glomerular nephritis. The order of toxicity is: sulphate, nitrate, acetate (corresponding to their hydrolytic dissociability). With all salts there is a marked diminution of toxicity with dilute solutions. For the sulphate there is a notable difference between the immediately lethal dose (0.5 to 1.3 mgm.) and the remotely fatal dose (0.00023 mgm.). Phosphates did not exert any demonstrable antidotal effect.—*H. C. Wood.*

1205. MORRELL, J. A., H. H. POWERS, and J. R. VARLEY. A new source of the ovarian follicular hormone. *Endocrinology* 14(1): 28-31. 1930.—The follicular hormone occurs in both amniotic and allantoic fluid of cattle in equal amounts. This is the richest source obtainable from slaughter houses. About 200 units per gallon of fetal fluid is obtained. The preparation is water soluble, non-toxic and has the physiological properties of the follicular hormone. It causes estrus in spayed rats, menstruation in ovariectomized monkeys and hastens sexual maturity as evidenced by the opening of the vaginal orifice.—*J. A. Morrell.*

1206. MOURIQUAND, G., et A. LEULIER. Recherches cliniques l'action antirachitique de l'hélistérine irradiée. *Paris Méd.* 19(44): 409-415. 14 fig. 1929.—The sterols of the edible snail *Helix pomatia* were chosen as the subject of experiment because of the snail's well known ability to repair its broken shell, because its blood contains 3 times as much Ca as human blood, and because the snail's cholesterol is chemically and physically comparable to human cholesterol. Some of this snail cholesterol was purified by successive crystallizations, while other samples of cholesterol containing traces of the associated sterols (called by the authors helisterine) were used without purification. Both were used on rachitic rats (number not stated). In the animal series the purified irradiated cholesterol showed no antirachitic effect; the irradiated helisterine (unpurified cholesterol)

showed a powerful antirachitic action. The irradiated helisterine, used in clinical cases (number not stated), relieved or cured some patients but had little or no effect on others, the latter being cases like those which give negative results with ergosterol and ultraviolet rays.

1207. NATALE, LUIGI DI. La nostra esperienza di terapia del cancro con il piombo colloidale. [Colloidal lead and cancer.] *Minerva Med.* 9(51): 997-1005. 1929.—Colloidal lead in 3 different preparations was used experimentally on 13 rabbits and therapeutically on 10 patients, necropsy being performed on all the animals, and on the clinical cases that ended fatally. No elective action on the cancerous cell was observed; in fact, in one case the lead was observed to be deposited in the sustaining tissues and not in the cancer cells, though injected into the neoplastic tissue. One of the preparations proved highly toxic; none gave any therapeutic effects.

1208. NEWMAN, ROLLO K. The relative rates of excretion in the urine and removal from the blood of lead after injection of colloidal lead and colloidal lead orthophosphate. *Med. Jour. Australia* 1(6): 170-177. 1930. —For several patients receiving colloidal lead injections the average excretion of Pb in feces was 2.91 mgm. and in urine 1.64 mgm. per week. The concentration in the urine averaged 0.33 mgm. per litre, varying from 0.97 mgm. to 0.19 mgm. per litre, figures similar to those recorded by other workers for cases of Pb poisoning. Blood was not present in the urine in any case. Albuminuria was common for 5-8 days after injection. It is believed that the therapeutic action of Pb is quantitative rather than qualitative.—*R. K. Newman.*

1209. NOMA, ARATA, und SHÔICHI SASAI. Über den Einfluss des Opiums auf den Kohlehydratstoffwechsel. [Japanese.] *Okayama Igaku Kwai Zasshi* 39: 1592-1606. 1927.—It was shown experimentally that opium in small doses can suppress alimentary hyperglycemia and glycosuria. In large doses hyperglycemia is produced, as with morphine. Experiments were made on well nourished rabbits utilizing opium, atropine, ergotamine, epinephrine, and insulin with the following results: Tincture of opium subc., 0.5 ccm. per kgm. per day over a 4 day period, produced in many animals a slight hyperglycemia only on the 1st day, while it became ineffective on the following day. Subsequently, the blood sugar rise following both oral and rectal administration of sugar was definitely reduced. Nevertheless, the glycemia following sugar intraven. was increased and prolonged, while the insulin sensitivity of the animals was more or less reduced. The glycogen content of the liver was not always reduced. With from 0.75 to 1 ccm. of tct. of opium a definite hyperglycemia was produced. Subc., atropine had no noticeable effect on the blood sugar, but with gynergen and with atropine and ergotamine combined, slight hypoglycemia was produced. After atropine and gynergen, separately or combined, the hyperglycemia following oral or rectal sugar administration was lower, but higher and more prolonged after intraven. injection of sugar. The insulin sensitivity of animals was likewise reduced. Epinephrine and opium hyperglycemia and primarily antagonizes prolonged in- it appears that opium probably depresses alimentary hyperglycemia and primarily antagonizes prolonged intestinal absorption of sugar rather than accelerating sugar mobilization. Opium in larger dosages actually produces a definite hyperglycemia due probably to an increased epinephrine secretion, comparable to the action of morphine. Therefore it appears that the action of opium in diabetes is associated with a disturbance of carbohydrate metabolism and should be employed with caution.—*Author (courtesy Jap. Jour. Med. Sci. IV) (transl. by. O. W. Barlow).*

1210. OGAWA, MASAYOSHI. Experimentelle Studien über den Wirkungseffekt des Insulins. I. *Folia Pharmacol. Japonica (Breviaria)* 8(3): 2-3. (Orig. in Japanese p. 157-178.) 1930.—The smallest effective dose of insulin in rabbits is 0.005 units per kgm., provided injection is made into the ear vein, carotid- or femoral artery or trachea. The min. eff. dose of insulin subc. or intramusc. is twice as large. The blood sugar begins to fall 10 min. after intraven. injection. After intraarterial injection the fall in blood sugar starts later, after subc. still later and latest after intramuscular injection (after 30 min.). After intraven. or arterial injection the hypoglycemia is of shorter duration than after the other types of injection. Two units per kgm. cause convulsions, irrespective of the mode of application. With larger doses hypoglycemia is more marked but not much more lasting. Convulsions usually occur when the blood sugar is lowest, rarely when it has begun to rise. A slow fall in blood sugar delays the onset of convulsions or even prevents them though the blood sugar may fall to a very low level. After intramuscular injection occasionally no convulsions occur. The minimal lethal and convulsive doses of insulin are practically identical. The effect of insulin is less dependent on the rate of absorption into the blood stream than that of most other drugs. —*Author's summary (transl. by G. T. Cori).*

1211. ORR, J. B., A. CRICHTON, and W. MIDDLETON. A note on the toleration of farm animals for high doses of iodine. *Vet. Rec.* 9(48): 1055-1056. 1929.—Experiments showed that doses of I up to 3 gm. daily for calves, 5 gm. for pigs, and 0.3 gm. for sheep and poultry can be administered over long periods without harmful effects.

1212. OSHIMA, SHIRO. Über den Einfluss der Salvarsaninjektion auf den Calciumgehalt im Blutserum. [Effect of injection of salvarsan on calcium content of blood serum.] (Japanese.) *Hokkaido Igaku Zasshi* 5: 193-202. 1927.—In men with positive Wassermann reactions, Ca was determined by the Clark and Collip modification of the Kramer-Tisdall method; K by the Kramer-Tisdall, and albumin by the Pulfrichs refractometer. The intravenous injection of salvarsan causes, in the 1st hour, a decrease in the Ca content of the serum, which returns to normal in 5 hrs. after the injection. Simultaneously, the K content shows a rising tendency. The Na content remains uninfluenced by the injection. The serum albumin shows a slight increase.—*Author (courtesy Japanese Jour. Med. Sci. IV) (transl. by C. C. Haskell).*

1213. OSTERBERG, ARNOLD E., MYER W. RUBENSTEIN, and WILLIAM H. GOECKERMAN. The absorption of sulphur compounds during treatment by sulphur baths. *Arch. Dermatol. and Syphilol.* 20(2): 158-166. 1929.—Sixteen patients presenting various pathologic conditions of the skin and 2 normal persons were given daily S baths for varying periods of up to 44 days. Blood and urine were analyzed for total S daily or semiweekly in some cases. Marked rise in conc. of S was observed in both fluids. The rise in S was greatest in the type of bath in which SO_2 is evolved.—*E. Smith.*

1214. OSTERMANN, GOTTFRIED. Die Wirkung stark verdünnter Salzlösungen auf den Blutdruck. [The effect of highly dilute salt solutions on blood-pressure.] *Arch. Exp. Path. u. Pharmakol.* 149(5/6): 257-262. 1930.

1215. PARTOS, ALEXANDER. Über die Wirkung des Curare auf den Kohlenhydratstoffwechsel, auf die Harnsekretion und über die Schutzwirkung der Leber dem Gifte gegenüber. *Pflüger's Arch. Ges. Physiol.* 223(1/2): 40-46. 1929.—Examples are cited from a series of experiments on rabbits. In all cases, within a few minutes after administration of curare, a hyperglycemia set in which could be controlled by simultaneous administration of insulin with the curare. Glycosuria was observed in only one case. During the intoxication marked concentration of the blood occurred, but disappeared during recovery; this did not take place if the ureters were ligated. During the intoxication the solids of the urine decreased considerably, but increased notably on the appearance of the first symptom of recovery. Curare impedes the secretory activity by damaging the urinary passages. Recovery of curarized animals in which the ureters had been ligated indicates that the liver is able to exert complete protective activity against curare if the excretion of the poison through the kidneys is prevented.

1216. PATTISON, C. LEE. Treatment of bone tuberculosis by large amounts of vitamins A and D. *Brit. Med.*

Jour. 2(3630): 178-179. 1930.—Preparations containing large amounts of vitamin A and vitamin D were fed to 43 patients with bone tuberculosis and codliver oil was given to 35 patients. About the same proportion of each series made similar progress toward recovery, indicating no more value in the vitamin preparations than in the codliver oil.

1217. **PEISACHOWITSCH, I. M. Kohlenoxyd und inkretorische Drüsen.** *Virchow's Arch. Pathol. Anat. u. Physiol.* 274(1): 223-229. 1929.—CO increases the activity of the suprarenals and also acts on other chromaffin organs. In acute CO poisoning there are histochemical changes in the colloid of the thyroid; in chronic poisoning extensive colloid formation.

1218. **PELLEGRIN, CH. Intoxication de chevaux par la naphtaline.** *Bul. Soc. Sci. Vét. Lyon* 32(3): 96-98. 1929.—Note.

1219. **PLATTNER, F., und H. HINTNER. Zur Frage der Saponinstromatolyse.** *Pflüger's Arch. Ges. Physiol.* 224(2): 293-296. 1930.—Saponins from 8 different manufacturers were used to hemolyze erythrocytes from different species of mammals. Observations on hemolysis were made by Ponder's ultra-microscopic method. All saponins hemolyzed erythrocytes at dilutions of 1: 100. Saponin Sthamer hemolyzed cats' blood and pigs' blood in dilutions of 1: 200; saponin Herniaria hemolyzed cats' blood in dilutions of 1: 1000, oxblood in dilutions of 1: 200 and pigs' blood in dilutions of 1: 400.

1220. **POWERS, H. H., J. R. VARLEY, and J. A. MORRELL. Preliminary note on the assay of the follicular hormone by vaginal administration.** *Endocrinology* 13(4): 395-398. 1929.—The estrus-inducing hormone was prepared in the form of a gelatin pessary for vaginal administration. The check of potency of the gelatin pessaries by injection of water emulsion of these pessaries in white rats showed that no loss in potency occurred in their preparation. The estrous cycle has been induced in spayed albino rats by vaginal administration of the follicular hormone. The ratio between the pessary dose and the subcutaneous dose is probably in the neighborhood of 3 to 1. Menstruation has been induced in spayed monkeys by the vaginal administration of these pessaries. As low as 150 units will induce menstruation in these animals.—*Authors' summary.*

1221. **PŘIBYL, E. K dusikovému metabolismu při experimentálních otravách. II. Subacutní otravy antimonem. (On the nitrogen metabolism in experimental poisoning. 2. Subacute antimony poisoning.)** [English summary.] *Biol. Spisy Vysoké Školy Zvěrolékařské Brno (Publ. Biol. École Haut. Études Vét.)* 6: 261-267. 1927.—In rabbits poisoned by Sb-K-tartrate the level of non protein N and urea N in blood, total non protein, urea and ammonia N in urine were followed. In all cases a rise of non protein and urea N has been found. The excretion of total and urea N in urine of poisoned animals is also very much higher. In Sb poisoning a rise of non protein N is not always due to rise of urea N. The ammonia N quotient in the urine seems to be inversely proportional to the urea N quotient. The increase in N metabolism is in Sb poisoning lower than the increase in As poisoning. Histological examination shows the pathological changes in liver and kidney to be less prominent. No influence of fatty degeneration of liver in urea content in blood and urine has been noticed. *From author's summary.*

1222. **RABBENO, A. Azione farmacologica del pirrolo. [Pharmacological action of pyrrole.]** *Bol. Soc. Med.-Chir. Pavia* 43(4): 439-443. 1929.—Pyrrole causes in the frog a poisoning characterized by a descending type of paralysis and muscular contracture. Locally applied it inactivates muscle, nerve and cutaneous receptors. Perfused through the heart and isolated central nervous system it inactivates them. The process is reversible. In the frog its toxic activity approximates that of a narcotic. The concentration that abolishes the reflexes in the isolated organ is about 1/10 that which stops the heart.—*A. Rabbeno (transl. by J. G. Edwards).*

1223. **RATH, ERICH. Kürbiskerne als Wurmmittel.** *Arch. Exp. Path. u. Pharmakol.* 142(3/4): 157-161. 1929.—The lipids extracted with ether, petroleum ether or alcohol from pumpkin seeds proved highly toxic for earthworms, while the husks and residue of the seeds were quite inactive.

1224. **ROBBINS, B. H. The absorption, distribution and excretion of carbon tetrachloride in dogs under various conditions.** *Jour. Pharmacol. & Exp. Therap.* 37 (2): 203-216. 1929.—The rate of absorption was studied indirectly by the rate of excretion of CCl_4 through the lungs. The thermal conductivity method of gas analysis was used. Rate of absorption was proportional to the size of dose, as shown by animals having an Eck fistula; fat and alcohol increase the rate of absorption. The drug was recovered from most tissues examined,—the bone marrow contained the highest concentration. There was no excretion of carbon tetrachloride in the urine.—*B. H. Robbins.*

1225. **ROFFO, A. H., y F. PILAR. La función heliotrópica de la colesterina. [On the heliotropic property of cholesterol.]** [With English, French and German summaries.] *Bol. Inst. Med. Exp. Estudio Trat. Cancér* 23: (1-9). 1930.—The results obtained complete those communicated before. They ascribe to cholesterol a positive heliotropism, a property in relation to the photoactivation described by others. On the other hand, these results agree with observations referring to the content of cholesterol in the skin, in parts exposed or not exposed to the sun. As a result of the investigation in man, the skin of the abdomen has ¼ as much cholesterol as the face. This phenomenon is observed even in the different parts of the head, where the skin of the nose presents an excess often as high as 100% in relation to the skin of the forehead, protected against the sun by the hat. These results are of interest in precancerous injuries and the hypercholesterolemia in precancerous conditions. Thus a relation may be established between this process and the extraordinary frequency of the localization of cancer on the skin of the face, as compared with the other localizations. Statistics on cancer morbidity show that 92% of the tumors of the face correspond to the parts exposed to the sun, while only 7% concern the skin of the forehead. Of the first group, 61.4% belong to the region of the nose. It is concluded that there is a relation of the heliotropic property of cholesterol to the fixation in the tissues and the production of tumor. —*A. H. Roffo.*

1226. **ROSE, CHARLES L., HAROLD W. COLES, and HELEN E. THOMPSON. Studies in the pharmacology of local anesthetics. III. Comparison of gamma-(2-methyl piperidino)-propyl benzoate hydrochloride with cocaine and procaine on experimental animals.** *Jour. Lab. & Clin. Med.* 15(8): 731-735. 1930.—No. 33, γ-(2-methyl piperidino)-propyl benzoate hydrochloride, has been compared pharmacologically with cocaine and procaine, by intraven. injection into rats and rabbits, subc. injection into mice and rats, and intraperitoneal injection into rats. (Number of animals not stated.) Subcutaneously given, No. 33 appeared less toxic than cocaine but more toxic than procaine. It was active by topical application to mucous membranes as well as by infiltration.

1227. **ROSE, WILLIAM C., and FLORENCE L. CATHERWOOD. Do baking powder residues exert injurious effects upon growth and nutrition?** *Jour. Nutrition* 2(2): 155-169. 6 fig. 1929.—Three baking powders (a Ca acid phosphate, a tartrate, and a mixture of Ca acid phosphate and anhydrous Na aluminum sulfate) were fed to 2 generations of rats. When incorporated in the diet in the proportions ordinarily employed in making bread and in twice these amounts, no detectable toxic or injurious action was found; growth and reproduction were as satisfactory as in control rats; and blood analyses and histological examinations of the kidneys failed to show evidence of injury.—*E. L. Batchelder.*

1228. **ROY, A. C., and K. C. SEN. On the inhibiting action of sucrose on taurocholate, saponin and oleate hemolysis.** *Jour. Indian Chem. Soc.* 6(1): 89-92. 1929.—

A study of the hemolysis of sheep's erythrocytes, both in isotonic saline as well as in isotonic sucrose, shows that sugar has a great inhibiting action on saponin, oleate, and taurocholate hemolysis. In both these solutions oleate has the highest hemolytic power, then comes saponin, and taurocholate has the least hemolytic power of the three.—*E. Ponder.*

1229. **SABATINI, GIUSEPPE. Modificazioni indotte nell'organismo umano da minime dosi di sali dei metalli oligodinamici. [Modifications of human blood by small doses of oligodynamic metals.]** *Policlinico. Sez. Med.* 36(6): 281-291. 1929.—Intravenous injection in fasting human subjects of one of the following solutions: $CuCl_2$, $ZnCl_2$, $HgCl_2$, 1 mg. in 2 cc. dist. H_2O, and 2 cc. dist. H_2O alone as control, gave a rise in R.B.C., leucocytes and blood sugar, except in the control. The red cells return to normal in 24 hours, and the blood sugar in 8 hours.—*J. Pi-Suner.*

1230. **SABATINI, G., e MARCO PAZZI. Modificazioni del tasso glicemico indotte negli individui iperglicemici e glicosurici da minime dosi di sali dei metalli oligodinamici. II. [Modification of the blood-sugar percentage in hyperglycemic and glycosuric persons by very small doses of salts of oligodynamic metals. II.]** *Policlinico. Sez. Med.* 37(7): 338-343. 1930.—Sabatini had previously found that very small doses of salts of oligodynamic metals, introduced into the human [normal] circulation, produced a transitory rise in the white and red blood counts and in the blood sugar (sometimes doubled). In this study 1 mgm. of $HgCl_2$ was given intravenously to 6 hyperglycemic and glycosuric subjects, and 1 mgm. $CuCl_2$ to a 2nd series of 6. In both series the chemicals (particularly the Cu salt), contrary to their action in normal conditions, depressed the hyperglycemia.

1231. **SATO, TAKAFUSA. Über den pathologisch-histologischen Einfluss des Lipiodols auf das Atemorgan und die bakterizide Wirkung desselben.** *Mitteil. All. Path. u. Path. Anat.* [*Sendai*] 5(2): 183-191. 2 pl. 1929.—Culturally lipiodol is sterile but without bactericidal action. Usually lipiodol does not cause a marked histopathological change in the respiratory system but does produce minor interesting changes, which differ in the lungs of dogs and rabbits. Lipiodol when introduced into the lungs is immediately taken up by the epithelium of the bronchial mucous membrane as granules, passing at the same time into the lymph spaces of the walls of larger bronchi, forming clumps. One to 3 days after administration phagocytes with ingested lipiodol appear in the alveoli in large numbers. Lipiodol granules are also seen in the cartilage cells. After 3 days numerous small aggregations of lymphocytes appear in the interstitial substance or in the alveolar walls, becoming more pronounced after 1 week and more so in the lungs of dogs. Three to 4 weeks later the above changes subside, but rather marked edema persists and the epithelial cells already show regeneration. After 47 days lipiodol is in part taken up by macrophages which appear to wander backwards through the air passages and be eliminated from the respiratory system. Furthermore the reaction in general decreases. After 93 days macroscopically no alterations are visible and histologically only the remains of the previous changes in which lipiodol granules are still seen. The changes described correspond with those reported by several authors as occurring in the meninges and spinal fluid after intraspinal lipiodol. —*W. H. Moursund.*

1232. **SCREMIN, LUIGI. Studio sull'antagonismo fra magnesio e farmaci convulsivanti. [The antagonism between Mg and convulsant drugs.]** *Arch. Internat. Pharmacodyn. et Thérap.* 36(1): 73-80. 1929.—In rabbits $MgCl_2$ intraven. prevented the convulsive action of many drugs. This effect is believed to be due to an action on the central nervous system by Mg, as is also the case with Ca.—*P. Popenoe.*

1233. **SHIOYA, NOBUO. Beiträge zur Pharmakologie des ausgeschnittenen Darmes. I. Mitteilung. II. Mitteilung. Über die Wirkungen der verschiedenartigen, an der Serosa- und Schleimhautfläche oder pervascular beigebrachten Medikamente auf das ausgeschnittene Dünndarmstück des Kaninchens.** [Japanese.] *Chosen Igaku Kwai Zasshi* 80: 687-692; 83: 1042-1073. 1927.—I. A method is described for observing effects of application of drugs to isolated segments of intestine on the serous side, on the mucous side, and by way of the mesenteric circulation. II. A study was made of the differences in efficiency of the ordinary intestinal drugs. —*Author* (*courtesy Jap. Jour. Med. Sci. IV*) (*transl. by C. Reynolds*).

1234. **SILVERBERG, MABEL G. The sensitization of the skin to mesotan.** *Arch. Dermatol. & Syphilol.* 21 (2): 166-179. 1930.—A bibliography is given of sensitization of the human skin with substances of known chemical composition by percutaneous or intracutaneous application. It is possible to make a certain number of persons locally and generally hypersensitive to mesotan (methoxymethyl ester of salicylic acid) by either repeated inunctions over a small area of skin with 10%-100% mesotan in olive oil or vaseline, or by rubbing with 100% mesotan, after mechanically irritating the skin.—*S. N. Blackberg.*

1235. **STEDMAN, EDGAR. Studies on the relationship between chemical constitution and physiological action. Part II. The miotic activity of urethanes derived from the isomeric hydroxybenzyldimethylamines.** *Biochem. Jour.* 23(1): 17-24. 1929.—The miotic activities of the methyl urethanes of the hydroxybenzyldimethylamines are in order ortho>para>meta. Conversion of the tertiary N into quaternary ammonium group increases the activity of ortho, diminishes that of meta, and abolishes that of para. The derivatives of choline iodide and of tropine were found inactive in 2% solution, confirming the view that miotics are substituted phenyl, as distinguished from alkyl, esters of carbamic acids. The ethyl and phenyl urethanes were not active.—*E. V. Lynn.*

1236. **STEINER, G., und VIKTOR FISCHL. Experimentelle Untersuchungen zur Pathologie und Therapie der Spirochätenkrankheiten. Über die Wirkung von Goldpräparaten bei experimenteller Recurrens.** *Klin. Wochenschr.* 8(13): 582-585. 1929.—Two new Au preparations were tried in African relapsing fever in mice and rats—solganal (disodium salt of 4-sulfomethylamino, 2-aurothiobenzol, 1-sulfonic acid) and preparation A 69. The chemotherapeutic index of both is higher than that of neosalvarsan and in contrast to previously used Au preparations they are efficiently prophylactic. Of fundamental importance is the fact that both gold combinations in the rat act as "therapia sterilisans magna" and destroy spirochaetes persisting in the central nervous system during the immune period.—*V. Fischl* (*transl. by E. Kellert*).

1237. **STEINMETZER, K., und F. SWOBODA. Experimentelle Untersuchungen über den Einfluss von Narkotica auf die Blutzuckerkonzentration.** *Biochem. Zeitschr.* 198(4/6): 259-267. 1928.—Dogs were fed daily on dog biscuit plus 50 gms. of meat. The normal blood sugar was determined by the Hagedorn-Jensen method. The animals were narcotized with ether, Billroth mixture, morphine, chloral hydrate or hedonal. Samples of blood were drawn at ½ hr. intervals for from 5 to 6 hrs. after the induction of anesthesia. An increase of from 30 to 50% in the normal blood sugar value was obtained following narcosis, and continued after narcosis had terminated. Small doses of chloral hydrate and hedonal which did not produce sleep caused prolonged hyperglycemia. It is concluded that hyperglycemia following narcosis is due to interference with the brain center regulating sugar metabolism.—*J. C. Munch.*

1238. **SÜSSMANN, HEINRICH. Experimentelle Studien mit Parathormone-Collip an weissen Mäusen.** *Zeitschr. Ges. Exp. Med.* 56(5/6): 817-830. 1 fig. 1927.—Analyses of 0.25 cc. samples of serum from normal mice showed this to contain about 20 mgm. Ca per 100 cc. Administration of parathormone, even in doses as large as 10 units per mouse (15 gm.), did not increase the Ca content of the serum nor produce any of the other symptoms of parathyroid overdosage. Mice treated

with parathormone were as susceptible to guanidine intoxication as were mice not so treated but, if the two were mixed before injection, 2 units of parathormone protected against 0.5 gm. guanidine per kgm., otherwise a fatal dose. There was a similar neutralizing action against picrotoxin but not against strychnine.—*I. Greenwald.*

1239. **SUZUKI, TAISUKE. Influence of intravenous administration of peptone upon the frequency of the denervated heart of the cat.** *Tohoku Jour. Exp. Med.* 12(5/6): 571-576. 1929.—Orally urethanized cats with vagi divided, and inferior cervical and stellate ganglia removed bilaterally, were given from 0.2-0.4 gm. per kgm. of Witte's peptone intraven. Acceleration of the cardiac rate immediately occurred, accompanied by fall in blood pressure. In view of these results plus a review of literature it is concluded that both the liberation of adrenaline and a direct action on the heart are concerned.—*O. S. Gibbs.*

1240. **SZILÁRD, ZOLTÁN. Die Wirkung des Natriumhydrokarbonat auf den Magen.** *Deutsches Arch. Med. Klin.* 168(5/6): 368-373. 1930.—The chloride of the gastric contents after administration of $NaHCO_3$ was studied in 44 cases, including normal, subnormal and hypernormal acidity. The Cl excretion in the gastric juice was increased after both oral and intravenous administration of $NaHCO_3$.

1241. **TANAKA, JITSUTARÔ. Über die antagonistische Wirkung des Cholins gegen die Adrenalinglykogenmobilisierung.** [Antagonistic action of cholin to glycogen mobilization by adrenaline.] [Orig. in Japanese.] *Folia Pharmacol. Japonica* 8(4): 281-288. (German summary, *Breviaria*, 6-7). 1929.—Cholin as well as adrenaline, when given subcutaneously to rabbits, raises the blood sugar. When given at the same time, cholin antagonizes the effect of adrenaline on the blood sugar. Therefore it is probable that the mechanisms of cholin and adrenaline hyperglycemia are different.—*Author's summary (transl. by G. T. Cori).*

1242. **TATUM, A. L., and M. H. SEEVERS. Experimental cocaine addiction.** *Jour. Pharmacol. & Exper. Therapeut.* 36(3): 401-410. 1929.—Rabbits, dogs and monkeys, and probably man, become sensitized rather than tolerant to cocaine habitually administered. Dogs exhibit a true cocaine psychosis with marked desire for the drug. Rabbits, unlike dogs, do not eliminate cocaine in the urine even with severe poisoning. The sensitivity acquired in dogs and monkeys persists unabated for at least 10 days. Dogs sensitized to cocaine are hypersensitive to other stimulants (ephedrine) and hyposensitive to depressants (morphine).—*Authors' summary.*

1243. **TERAO, ARATA, and TOMOZÔ TANAKA. Anaesthesia of the water-flea, Moina macrocopa Strauss, in relation to age.** *Jour. Imp. Fish. Inst.* [*Tokyo*] 25(1): 13-14. 1 fig. 1929.—Anesthesia is observed at 27° C. with 1/50 mol. solution of chloretone on monoclonal population of parthenogenetic ♀ of the water-flea reared at a constant temp. of 27° C. A curve which is nearly an ascending parabola and represents time required for anesthetizing the water-flea, plotted against age from hatching to 10 days thereafter, shows 2 drops: with those which are 4-5 and 9-10 days old respectively.—*A. Terao.*

1244. **TSUGE, MOMOTA. On the influence of some diuretics upon the gastric juice.** [In Japanese.] *Nihon Shokwakibyogakkwai Zasshi* 28(1/3): 1-36. 1928.—During diuresis the chlorine content of the blood decreases and the serum albumin increases. Quantity and acidity of the gastric juice diminish during these changes and also during alkalosis, while they increase under the reverse condition. Caffeine sodium benzoate and sodium acetate, which raise alkalinity of the blood, reduce the quantity and acidity of the gastric juice and, consequently, the appetite. The diuretics, euphyllin and novasurol, which lead to acidosis, produce smaller fluctuations in conditions of the gastric juice than those previously named, and so do not disturb the appetite. These actions of diuretics upon the gastric juice and appetite cease with discontinuance of the drug.—*M. Tsuge (transl. by E. V. Lynn).*

1245. **UCHIGAKI, SHUICHI. On the influence of various drugs on the internal pressure of the urinary bladder.** [Japanese.] *Kinki Fujinkwai Gakkwai Zasshi* 10: 1109-1129. 1927.—Laparotomy was performed on rabbits and the bladder was exteriorized. Ringer's solution at 38° C. was poured into the bladder in the proportion of 10 c.c. to every 1000 gm. body weight, the organ being thus moderately distended, and a glass catheter was inserted at the vesico-cervix. The catheter was connected with a manometer, filled with chloroform with a light glass ball afloat on it. To the glass ball a lever of straw was attached, which recorded its movements on a kymograph. By these means the influence of various drugs injected intravenously on the internal pressure of the bladder was observed. The results may be summarized as follows:—Pilocarpine and physostigmine raise the internal pressure. Atropine can lower the pressure raised by these drugs, but when administered alone it shows as a rule no remarkable influence. Adrenaline and nicotine produce a temporary rise of the pressure, and then a fall. Morphine effects in a small dose a rise of pressure but in a large dose only a slight fall. Cocaine, quinine, Ba, strychnine and pituitrine always increase the pressure. Urotropine shows first a temporary fall, then a gradual rise, which lasts about 50 min.—*Author (courtesy Japanese Jour. Med. Sci. IV).*

1246. **UHLMANN, FRITZ. La Percaine (chlorhydrate de la diéthyléthylènediamide de l'acide α-butyloxycincheninique).** *Arch. Intern. Pharmacodyn. et Thér.* 36(3): 263-271. 1929.—In the group of quinine derivatives substances have been found which cause local anesthesia of an intensity and duration unknown hitherto. The most remarkable of these substances is percaine. The limit of activity of percaine on the cornea of the rabbit is 1: 125,000 as compared with 1: 2500 for novocaine, 1: 3000 for tutocaine, 1: 10,000 for cocaine. Percaine 1: 1000 causes anesthesia of the cornea lasting 3 hrs., while with novocaine of equal concentration the anesthesia lasts 20 min., with tutocaine 30 min., and with cocaine 40 min. The toxicity of percaine is about 5 times that of cocaine, its anesthetic power at least 10 times greater. Percaine is readily absorbed by the mucous tissues (frogskin) and by the nerve tissue. In therapeutic concentrations it causes no local secondary effects. It may be combined with epinephrine, such combination often being desirable, because concentrated percaine solutions cause a slight vasodilation. Percaine solutions may be sterilised by boiling. Percaine hydrochloride is readily precipitated from its solutions by alkalis, but is redissolved by a few drops of highly dilute HCl.—*F. Uhlmann.*

1247. **UMEDA, T., and S. SHIBATA. The influence of photodynamic action on the movement of the epithelium of the urinary bladder. (A study in tissue-culture method.)** *Arch. Exp. Zellforsch. Bes. Gewebezücht.* (*Explantation*) 7(3): 344-351. 3 fig. 1928.—Cultures of urinary bladder epithelium of the frog, *Rana esculenta*, were made by the hanging-drop method, and were grown in both light and darkness. Fluorescent dyes (trypaflavin, eosin A, erythrosin, methylene blue, uranin and florida red) did not retard the growth or movement of tissues grown in the dark, but did of tissues grown in light. Fuchsin and water blue, 2 non-fluorescent dyes, produced no retardation of either growth or movement of tissues grown in light.

1248. **VINCENT, SWALE, and J. H. THOMPSON. Saline injections.** *Jour. Pharmacol. & Exp. Therap.* 36 (1): 107-114. 1929.—Injections of normal saline have considerable effect upon blood pressure. A series of experiments have been performed showing the influence of the quantity injected, rate of injection, temperature of the solution, composition of the solution, and the mean blood pressure. Indications are given of what effects upon the blood pressure may be expected under different conditions, and the importance of control injections is demonstrated.—*Authors' summary.*

1249. WAKABAYASHI, YOSHIAKI. Über den Einfluss der ins Blut eingeführten verschiedenen Substanzen auf die Serumeiweissmenge. [Japanese.] *Osaka Igaku Kwai Zasshi* 26: 2731-2736. 1928.—Serum albumin decreases at once after injections of Eryosan, Kaseosan, normal horse serum, and distilled water, but after 24-48 hrs. has returned to normal. Ten % NaCl, or 5% $CaCl_2$ solutions, cause no perceptible decrease. The increase or decrease of serum albumin corresponds closely with the number of blood corpuscles.—*Author (courtesy Japanese Jour. Med. Sci. IV.). Translated by R. H. M'Gonigle.*

1250. WALBUN, L. E. Metallsalztherapie. Kombination von Metallsalztherapie und Serumtherapie. *Zeitschr. Immunitätsforsch. u. Exp. Therap.* 49(6): 538-550. 1927.—The author has shown that, by combined treatment with vaccine and a metallic salt (of manganese), or by treatment with serums and metallic salts, animals, which had received lethal doses of pathogenic bacteria, were saved from death. These results could not be obtained by treatment with serum alone, or vaccine alone, or metallic salts alone. Similar results were obtained with animals which had received lethal doses of tetanus, diphtheria or dysentery toxin. The solution of the metallic salts must be of a concentration which is neither too great nor too small.—*P. G. Heineman.*

1251. YAMAGAMI, MATAO. Über die Einflüsse des Cholesterins auf die Wirkung einiger Pharmaka. [Japanese.] *Chosen Igaku Kwai Zasshi* 83: 1019-1028. 1927.—Since Ransom showed that cholesterol neutralizes the hemolytic action of saponin, many investigators have attacked the question of the detoxicating action of cholesterol. Experiments on the isolated intestine of the rabbit indicate that cholesterol neutralizes the action of saponin, $BaCl_2$ and chloral hydrate.—*Author (courtesy Japanese Jour. Med. Sci. IV) (transl. C. C. Haskell).*

1252. YANT, W. P., F. A. PATTY, H. H. SCHRENK, and L. B. BERGER. The response of Japanese waltzing mice and canaries to carbon monoxide and to atmospheres deficient in O. *U. S. Bur. Mines Rept. Invest.* 3040. 12p. 1930.—In atmospheres containing below 0.25% CO the sensitivity of waltzing mice (*Mus wagneri rotans*), canaries, and white mice decreases in the order named. Waltzing mice and canaries are about equally sensitive in concentrations from 0.20 to 0.25% and give indications safely in advance of a moderately exercising man. With 0.10 to 0.12%, however, canaries fail to give adequate warning symptoms while waltzing mice give distinct indications in 5 to 10 min. and well in advance of serious harm to man when his activity does not exceed that of walking. Neither canaries nor mice are sufficiently sensitive to atmosphere deficient in O to be of practical use in avoiding harmful exposure of man.—*W. P. Yant.*

1253. YOSHIMATSU, GUNSHI. Ueber das Verhalten der aromatischen Ester gegen Organauszüge. III. Mitteilung. Ueber die Wirkung des Organextraktes auf Benzoesäure- und Salicylsäurephenylester. *Acta Scholae Med. Univ. Imp. Kioto* 11(4): 639-648. 1929.—The benzoic acid ester is more easily hydrolyzed by organ extracts than the salicylic acid ester and the phenol esters are more easily hydrolyzed than the isobutyl, amyl and glycerol esters. The liver and kidneys of the pig contain more esterase than the pancreas, which is able to split the simple as well as the aromatic esters. However, these organs do not contain as much lipase which is necessary for the hydrolysis of higher glycerides. The action of glycerine extracts of mucous membrane of stomach and intestine, of kidneys, pancreas and liver, upon benzoic acid phenyl ester and salicylic acid phenyl ester is tabulated. All organs of the pig hydrolyze benzoic acid phenyl ester, the liver and kidneys being the strongest. The action of the organ extracts upon salicylic acid phenyl ester is much less than upon tributyrin.—*F. R. Greenbaum.*

1254. YOSHIMATSU, GUNSHI. Ueber das Verhalten von Aethyl- und Phenolschwefelsäure gegen Organextrakte. [The behavior of ethyl and phenyl sulphuric acid in organ extracts.] *Acta Scholae Med. Univ. Imp. Kioto* 11(4): 649-660. 1929.—Extracts of mucous membranes of stomach and intestine, kidney, liver and pancreas have no hydrolysing action on these salts, while tributyrin solution, used in the control experiments, was considerably hydrolysed. No organ extract had a hydrolytic action on potassium ethyl sulphate, neutralized potassium ethyl sulphate or potassium phenol sulphate.—*F. R. Greenbaum.*

1255. YOSHIMURO, SHIGEO. Über den Einfluss verschiedener Ionen auf den Blutzucker. [Japanese] *Nagasaki Igaku Kwai Zasshi* 5: 803-814. 1927.—The blood sugar of rabbits is affected as follows by various ions. Mg salts cause a slight increase; Ca, Sr, Ba and Na salts cause a marked increase; K salts produce an irregular action.—*Author (courtesy Japanese Jour. Med. Sci. IV) (transl. by A. J. Clark).*

1260. **ACHARD, CH., A. GRIGAUT, A. LEBLANC, et MARCEL DAVID. L'équilibre lipoïdique du sérum sanguin dans les maladies aiguës.** *Jour. Physiol. et Pathol. Gen.* 26(3): 415-425. 13 fig. 1928.—In acute febrile diseases the % of unsaturated fatty acids in the serum diminishes. An increase occurs during convalescence. Apparently, in the early stages, when the resistance of the organism is lowered, it loses some of its ability to desaturate the fatty acids.—*C. Achard (transl. by M. Bodansky).*

1261. **AMANTEA, G. Sui limiti della partecipazione corticale ai fenomeni convulsivi dell'epilessia sperimentale. [Limits of the part played by the cortex in experimental epileptic convulsions.]** *Arch. Sci. Biol.* [*Napoli*] 12: 413-420. 1928.

1262. **AULER, H., H. SCHLOTTMANN, W. RUBENOW, P. MEYER, und B. WOLFF. Arbeitsbericht aus dem Alten Ca-Laboratorium.** *Zeitschr. Krebsforsch.* 32 (1/2): 186-198. 1930.—This is a condensed account of a number of unrelated researches on cancer, some of which have already received more extensive publication. It includes an account of anaphylactoid reactions obtained by the injection of cancerous blood into tumors, of the peculiar interrelations of excessive fibrinogen in cancerous exudates with the shielding action of this on complement, of the somewhat inconstant results on sugar production from liver glycogen on the addition of blood plasma, on the production of specific antibodies to tumor cells,—in this they report success,—and on the effects of such antibodies on tumor inhibition. Also it includes an investigation of the source of melanin in the melanotic tumors; an extract of adrenal cortex furnished a ferment which, acting on phenol derivatives, produced a reddening of the solution, apparently by oxidative action. It was hoped that the introduction of this oxidative system might influence the fermentative activities of tumor cells. Evidences to this effect were obtained in the form of necrotic ulceration of (inoculated) tumors, usually with an accompanying severe and often fatal intoxication. Similar effects were observed with oxidative ferments derived from various moulds.—*H. E. Eggers.*

1263. **BAYER, GUSTAVO, e R. von den VELDEN. Trattato clinico di incretologia ed incretoterapia. Traduzione Italiana riveduta GUIDO VERNONI. Parte Generale. [Clinical treatise of endocrinology and organotherapy. Rev. Italian transl.]** 382p. illus. Ist. Sieroter. Milanese: Milan, Italy. 1928.—This is the first volume of Vernoni's 2-vol. Italian translation from the German of Bayer's and von den Velden's treatise on clinical endocrinology. After a historical introduction by Richard Koch, there is an exposition of present-day knowledge of the structure and function of the endocrine tissues by Bayer. This is followed by a general treatment of diagnosis and therapy of endocrine disorders by von den Velden. There has been added a chapter upon the insulin treatment of diabetes and another concerning the treatment of minor degrees of endocrine disturbances by G. Capone. A 2nd vol. dealing with the clinical endocrine maladies is to follow. The work is intended for the practitioner. As a whole the subject is stated simply, accurately and conservatively.—*R. M. Moore.*

1264. **BIENENSTEIN, ERWIN. Zur Kenntnis der Encephalitis post vaccinationem.** *Zeitschr. Kinderheilk.* 49(3): 248-258. 1930.—Animal inoculation (instillation into the eye, intracutaneous and intratesticular injection into rabbits) of the cerebrospinal fluid from 5 patients with postvaccinal encephalitis was uniformly negative in results. Bienenstein is inclined to place postvaccinal encephalitis in the group of para-infectious encephalitides.

1265. **BLOTNER, HARRY. The effect of liver on the blood sugar of diabetic patients.** *Jour. Amer. Diet. Assoc.* 5(2): 102-107. 1929.—Test meals were designed to contain equal quantities of carbohydrate, protein and fat, but one contained raw liver pulp, the other lean beef. Blood sugars were determined before ingestion, and at intervals of 3 hrs. afterward. A very marked drop in the blood sugar was noted in each instance. This was compared to the drop produced by the administration of 13 units of insulin. A case is reported in which the patient was enabled to discontinue 10 units of insulin twice daily by eating liver.—*W. W. Herrmann.*

1266. **BRIEGER, ERNST. Zur Physiologie und Pathologie der Arbeit beim Phthisiker.** *Jahresber. Ver. Schles. Ges. Vaterländ. Cultur: Med. Sect.* Pt. 2. 1928: 141-150. 1929.—Patients with pulmonary tuberculosis performed work on an ergometer and the effect on their O consumption, CO_2 output, and pulse rate was noted. There is no specific change in the energy processes of a tuberculous individual. Even though he has marked debility and lowered vital capacity he can carry on with good efficiency and normal restitution. Such diminution in efficiency and retardation of restitution as he has are common to weak and unskilled individuals. Maintenance of the pulse and respiratory rates indicate capacity for work while over-ventilation, fall in alveolar CO_2 and tachycardia denote the opposite condition. Such disturbances are due essentially to an incongruity between lung ventilation and the circulation and depend upon stasis in the pulmonary circulation.—*C. J. Bucher.*

1267. **BRUYNOGHE, R., et P. VASSILIADIS. La splénectomie dans l'infection du Tr. lewisi.** [Apparently *Compt. Rend. Soc. Biol.* 1929: 1-5. 1929.] *Trav. Inst. Bact. Univ. Louvain* 1927/1928: 5p. [1929].—*Tr. lewisi* is infectious only for rats. Splenectomy makes the dwarf mouse (*Mus minutus*) equally receptive to this infection. —*R. Bruynoghe.*

1268. **BUSCAINO, V. M. Contributo allo studio della patogenesi della "encefalite epidemica" e delle sindromi croniche postencefalitiche. [Pathogenesis and sequelae of sleeping sickness.]** *Riv. Patol. Nerv. e Ment.* 31(2): 116-160. 20 fig. 1926.—The author holds that the localization of the "microörganism" of epidemic encephalitis in the mesencephalon and basal ganglia is due to a lower resistance of those regions, brought about by the penetration, in circulation, of basal organic substances (probably amines) of intestinal origin. This is confirmed by the occurrence of serious lesions of the mesencephalon, produced experimentally in animals intoxicated by pregnancy or by histamines; and by the whole series of studies of experimental toxic syndromes following production of Eck's fistula. All these syndromes have features in common resembling extrapyramidal syndromes, including the postencephalitic. The intestinal origin of the postencephalitic syndrome is supported by a review of the literature and by citation of a case of postencephalitic parkinsonism in which the author found lesions of the intestinal mucosa.—*V. M. Buscaino (transl. by P. Popenoe).*

1269. **CHIRON, V., und S. SCANDURRA. Über Leberzellveränderungen, die mit der Zerstörung organischen Eiweisses zusammenhängen. Bedeutung in der Chirurgie.** *Deutsche Zeitschr. Chir.* 216(1/2): 89-97. 3 fig. 1929.—The authors observed 2 cases with slight liver damage which after abdominal operations developed fatal acute yellow atrophy. They produced slight liver damage experimentally in animals by injecting egg albumin and

by introducing animal tissue intraperitoneally. Abdominal operations in cases with grave functional hepatic disturbance are serious and the liver function should be studied before operation.—*V. Chiron* (*transl. by E. A. Baumgartner*).

1270. **CRISTOL, PAUL. Interprétation des valeurs de la réserve alcaline du plasma sanguin au cours des cétoidoses.** *Arch. Soc. Sci. Med. et Biol. Montpellier* 10 (): 350-352. 1928/1929.—Cristol cites illustrative cases to prove that the apparently normal alkaline reserve sometimes seen in diabetes with high ketonuria is really an artefact due to a poor technique, namely, the decarboxylation of the actyl-acetic acid of the blood by the Van Slyke method.

1271. **CUNEO, GEROLAMO. Studi sulla patogenesi della epilessia. Nota X. Il chimismo dei sali organici ossidabili e l'insufficienza della funzione ossidante del fegato. [Studies on the pathogenesis of epilepsy.]** *Riv. Psichiatria* 17(2): (5-52). 1929.—The author has studied the acidity of the feces, the effect of alkaline therapy, liver function with relation to oxidizable organic salts and the tolerance of the epileptic organism to these salts. The liver is found to have a decreased oxidizing function which allows absorption in the blood of deleterious acid substances in epileptics.—*E. A. Baumgartner.*

1272. **DEVOTO, LUIGI. Sugli esiti lontani di febbri tifoidi. [Remote sequelae to typhoid fever.]** *R. Ist. Lombardo Sci. e Lettere, Rend.* 62(16/20): 920-922. 1930. —Clinical experience over 20 years, with some 3000 typhoid patients, has shown that in later years such patients are very liable to digestive disorders, particularly of chronic character: constipation, appendicitis, colitis, etc.

1273. **DUKE, W. W. Heat and effort sensitiveness; cold sensitiveness: relationship to heat prostration, effort syndrome, asthma, urticaria, dermatoses, noninfectious coryza and infections.** *Arch. Internal Med.* 45(2): 206-240. 10 fig. 1930.—Duke reports a further study of a syndrome of symptoms caused in certain patients by heat and effort sensitiveness and in others by cold sensitiveness. The manifestations of sensitiveness varied in different individuals. In some cases it appeared as heat prostration, in others as effort syndrome, in others as asthma, urticaria, dermatoses or noninfectious coryza. Symptoms complained of by the patients could not be distinguished clinically from those caused by sensitiveness to pollens or foods. The patients, in many instances, gave no evidence of sensitization to material substances either by skin testing or dietary testing. Symptoms could be reproduced, however, by the suitable application of heat or effort or by cold. Strange to relate, in many instances the symptoms could be reproduced by the application of heat to the arm or of cold to the arm distal to a tourniquet around the upper arm which cut off the circulation of blood. In the case of reaction produced in this way, immediate relief could be obtained by the reversal of the application. The simultaneous application of heat to one arm and cold to another in cases of this sort gave rise to no reaction whatever. Duke believes that this type of illness is caused by a disorder in the higher heat regulating mechanism so that the body, instead of reacting normally for the purpose of retaining or losing heat, reacts ineffectively, pervertedly or excessively and in this way produces an illness. Symptoms can involve apparently not only organs such as the skin, nasal or respiratory membranes which are designed to control the rate of heat loss but can involve a given organ such as the brain or heart which if not adequately cooled after activity displays a disordered function. A distinction was made between primary and secondary cases—that is, those in which an adequate pathology could be found to cause a disorder in the heat regulating mechanism and those in which the individual seemed to be in perfect health except for manifestations of sensitiveness to heat or cold. In the latter type of case, the illness frequently followed a febrile disease. He believes that febrile diseases frequently cause a lasting dysfunction in the complicated heat regulating mechanism. The illness may be temporary or permanent and may be mild or excessively serious. In the latter case, it may completely incapacitate a person—in fact, may confine him to bed or to the house for years. Tests proving such a diagnosis can be and should be made objectively. If heat and effort sensitiveness or cold sensitiveness occur in an individual who is also sensitive to pollen, epidermal substances, or a food, the patient is naturally worse than if he is affected by only one of these agents at a time. Treatment by heat and effort avoidance or by cold avoidance and treatment by increasing heat tolerance or cold tolerance through frequent reversal of general applications of heat and cold is advised and in cold sensitive cases usually gives a very gratifying result.—*W. W. Duke.*

1274. **EBINA, TOSHIAKI. Über den Stoffwechsel des Kaninchensarkoms.** *Tohoku Jour. Exp. Med.* 13(5/6): 424-444. 1929.—Metabolism of rabbit sarcoma cells was studied with the improved Warburg technic, in Ringer solution. Observations were made of the tissue respiration and glycolysis of rat kidney, liver and Flexner-Jobling tumor, followed by studies on rabbit liver, kidney, spleen, cerebral cortex, heart muscle and testes. Finally Kato's rabbit sarcoma was studied. Following are the results: Oxygen consumption of rabbit sarcoma cells is normal, i.e., equal to that of normal tissue cells. Anerobic glycolysis of rabbit sarcoma is 25 times as great as that of heart muscle, and 2.5 times that of rabbit spleen. Aerobic glycolysis of rabbit sarcoma is high compared with that of normal tissues. The Meyerhof quotient and the Warburg quotient of rabbit sarcoma are abnormally high.—*T. Ebina* (*transl. by W. N. Berg*).

1275. **FINKELSTEIN, H. Zur Kenntnis des alimentären Fiebers. 3. Mitteilung. Das Harnstofffieber.** *Zeitschr. Kinderheilk.* 49(3): 207-209. 3 fig. 1930.—"Several" clinical observations show that urea (100-150 gm. per kgm.) in protein-free dietary mixtures produces no fever, but addition of protein, even in small amounts, very quickly produces elevation of temperature. This is not, properly speaking, "urea fever," but in part also a protein fever, caused by the fact that the water needed for the protein metabolism has been previously sequestered by the urea dehydration. Urea-rich foods accompanied by very inadequate amounts of fluids produce a fever, even in the absence of protein, which may justly be called a "urea fever." [Paper 1 in this series, by A. ABT, ELSE ASCHENHEIM and H. FINKELSTEIN, "Uber das Eiweissfieber," appeared in *Zeitschr. Kinderheilk.* 49 (1/2): 31-54; Paper 2, by H. FINKELSTEIN and W. JONAS, on "Der N-Stoffwechsel beim Eiweissaureicherungsfieber," ibid., 55-63.]

1276. **FRIESZ, JENÖ, und IMRE HALLAY. Serumlipaseuntersuchungen bei Leberkrankheiten.** *Zeitschr. Klin. Med.* 113(2): 275-280. 1930.—In none of 10 subjects with normal liver and kidneys could quinin-resisting lipase be found in the blood-serum. In each of 4 cases of simple jaundice, 4 cases of salvarsan icterus, 1 case of hepatic gumma and 1 case of hepatic lues, quinin-resisting lipase was invariably found in the blood-serum. In cases in which possibly no acute lesion of the hepatic cells existed, this lipase was sometimes found and sometimes not; thus, it was found in 3 out of 8 cases of cirrhosis of the liver and in 3 out of 7 cases of stasis liver ("Stauungsleber").

1277. **FUNK, ELMER H., and HUSTON ST. CLAIR. Hemochromatosis. Report of a case, with studies of the copper content of the liver.** *Arch. Internal Med.* 45(1): 37-45. 3 fig. 1930.—In a case of hemochromatosis that came to autopsy the Cu content of liver was 140 mgm. per kgm. of fresh tissue or 331.8 mgm. for the entire liver. Cu content of the spleen was less than 1 mgm. The Fe content of the liver for which an accurate determination method was not found was at least 6.2 gm. per kgm. of tissue or 14.7 gm. for the entire organ. The author suggests that Cu from the food is retained in hemochromatosis method of being excreted as it is in normal individuals.

1278. **GAESSLER, E. O. Über das Verhalten von**

Blutmilchsäure, Alkalireserve und Blutzucker bei puerperaler Infektion. *Zeitschr. Ges. Exp. Med.* 72(5/6): 726-752. 3 fig. 1930.—Calculations of average blood lactic acid, alkali reserve and blood sugar for the various stages of puerperal infection, drawn from 49 cases to produce objective outlines of the disease picture.

1279. GILDEMEISTER, E., und HOTORI WATANABE. Zur Bestimmung kleinster Mengen von Diphtherietoxin und Diphtherieantitoxin. *Zentralbl. Bakt. I. Abt. (Orig.)* 117(7/8): 464-470. 2 fig. 1930.—Several series of experiments (about 26 tabulated) on rabbits and guinea-pigs showed that intracorneal injection into the rabbits indicated the presence of amounts of diphtheria toxin at most 1/10 as great as those demonstrated by Paul H. Römer's intracutaneous method. Intracorneal injection of diphtheria toxin produces in the rabbit a severe keratitis with destruction of the corneal epithelium and inflammation of the other eye, the degree of inflammation corresponding to the amount of the injected toxin; injection of extremely small amounts of either diphtheria toxin or antitoxin produces a circumscribed smooth-margined ulcer, demonstrable on the living animal by the fluorescent test, and on the dead animal by the Paul method after enucleation. Similar changes were produced in the rabbit's eye by intracorneal injection of gangrene toxin, but no more marked than the changes produced by it on the guinea-pig's skin. No macroscopically recognizable changes were produced on the rabbit's eye by intracorneal injection of tetanus, botulinus and Shiga toxins.

1280. GOORMAGHTIGH, N. Le foie dans l'anémie pernicieuse. Considérations anatomo-pathologiques. *Bruxelles-Méd.* 9(6): 166-171. 1929.—The cause of pernicious anemia is an infectious or toxic agent acting through intervention of the liver. A preexisting vulnerability of this organ is assumed.—*J. Furth.*

1281. GRUNKE, WILHELM. Akuter Infekt und Fermente. I. Mitteilung: Harndiastase bei akuten Infektionskrankheiten. *Zeitschr. Klin. Med.* 113(5/6): 782-792. 1930.—In a series of about 145 cases of infectious diseases the diastase in the urine was determined by Wohlgemut's method. A regular increase in urinary diastase was observed in typhoid and in facial erysipelas. In diphtheria, scarlatina, tonsillitis and other infectious diseases diastase was increased in about 50% of the cases. In almost all cases a return of diastase to normal was seen in convalescence. The investigations seemed to show a relation between the severity of the case and the height of body temperature on the one hand and the height of the diastase values on the other. Such relation could not be definitely ascertained in the other infectious diseases. The increase of urinary diastase is attributed to a functional disturbance of the pancreas, and, in the cases of facial erysipelas, of the parotid gland. —*From author's summary (transl.).*

1282. HASHIMOTO, TAKASHI, und TAKESHI OHNO. Über Alopecia hyperkeratosis cystica follicularis. (In Japanese, with German summary p. 25-26.) *Japanese Jour. Dermatol. & Urol.* 29(4): 308-317. 3 fig. 1929.—The first patient, a woman 50 years of age, had suffered for a long time from an itching desquamative process of the scalp. The condition growing worse the patient consulted the clinic in June 1927. General examination was negative. There were bald areas on the vertex and in the occipital region of the scalp, the remaining parts showed a diffuse alopecia. The epidermis and the hairs were covered with abundant whitish scales. The openings of the follicles were plugged with comedolike horny material which could be expressed with the fingers. The condition cleared up under ultraviolet radiation and application of an ointment containing phenol and salicylic acid. Biopsy: The epidermis is thin and atrophic. The pigment granules of the basal layer are almost completely absent. The cutis likewise shows some atrophy. The hair follicles are transformed into cysts filled with homogeneous corneous material. The hair and the structure of the sebaceous gland could not be differentiated. Patient 2 was a woman 40 years of age with diffuse alopecia. Scalp and hair were dry. There were no signs of inflammation. The follicular openings were plugged with dark brown horny material, the histologic picture was the same as in case 1. The 3rd patient, a woman 35 years old, presented an identical clinical picture after a salvarsan reaction. A histologic study of this case was not carried out.—*Authors' summary (translated by J. A. Gammel).*

1283. HEDON, L. Le quotient respiratoire et le métabolisme de base dans le diabète pancréatique expérimental. (2me mémoire.) *Arch. Internat. de Physiol.* 27(3/4): 254-303. 3 fig. 1926.—Following a review of the literature on the respiratory quotient in human diabetes and in depancreatized dogs the author gives the results which he has obtained in 14 depancreatized dogs. The tables contain the data from more than 200 experiments. Detailed observations on each animal are given. The following facts were determined in these experiments: 1. The respiratory quotient rarely falls below 0.71 in the completely depancreatized dog. The maximum fall occurred on the 2nd or 3rd day after the onset of the diabetes. 2. The respiratory quotient then rose immediately and returned to the normal value: 0.75 for the fasting state. 3. It rose abruptly to a higher value, up to 0.8, just before death, when the latter was caused by diabetic cachexia after maximum emaciation. The following conclusions are drawn: The study of the respiratory quotient in the depancreatized dog offers no proof in the favor of the formation of glucose at the expense of fat. The quotient slightly below 0.70 found in some cases, especially with approaching coma caused by the sudden withdrawal of insulin after long treatment with this hormone, may be explained by the acidosis. The return of the quotient to nearly normal values may be explained by a relative increase on the part of protein in the total metabolism. The sudden antemortem elevation is very difficult to explain. It cannot be attributed to the phenomenon of "blowing off" since a study of the alkaline reserve eliminates this as a cause. The author compares these quotients with the very high quotients which have sometimes been found in severe diabetes in man. The idea emerges as a working hypothesis, that in the diabetic the power to oxidize glucose has not been lost and that the respiratory quotient is a mean value resulting from the combustion of carbohydrate on one hand and the formation of carbohydrates at the expense of O-poor substance on the other. As this last process diminishes in intensity with approaching death, perhaps as a consequence of the exhaustion of fat reserve, the quotient of the combustion of carbohydrate tends to appear more and more distinctly.—*L. Hedon (transl. by J. B. Youmans).*

1284. HOLLÓS, LUDWIG. Untersuchungen und kritische Bemerkungen über die neue Ikterustheorie von Brugsch. *Deutsche Med. Wochenschr.* 55(47): 1968. 1929. —Chemical tests lead Hollós to conclude: The Brugsch reaction cannot be elicited in a normal skin. It is produced in severe icterus independent of origin and duration of the condition, and not only on the jaundiced skin but in every secretion containing bilirubin (serum, urine, duodenal secretion, chemically pure bilirubin). It is therefore not an iron reaction but a bilirubin reaction. Consequently it throws no light on the local origin of bilirubin and lends no support to the theory of Brugsch. The reaction is not applicable to differential diagnosis.

1285. HUEBER, WALTHER. Beitrag zur Frage der Agranulozytose. *Frankfurter Zeitschr. Path.* 40(2): 312-356. 4 fig. 1930.—From a study of literature and of 2 cases personally observed, Hueber concludes that agranulocytosis is not an independent disease but a symptom-complex in septic infections.

1286. JENSEN, JULIUS. The adrenalin test in hypertension. *Amer. Heart Jour.* 5(6): 763-780. 6 fig. 1930. —It appears from the literature that the response to adrenalin in the patient with hypertension differs from that of the normal person, but the evidence as to the variations in response is contradictory. Under ap-

approximately standard conditions subcutaneous injections of 1 cc. of adrenalin were given to a number of normal persons, patients with hypertension, and others in whom the reaction was thought to throw light on the phenomena observed in hypertension. Persons with normal cardiovascular systems responded with a slow rise and a subsequent slower decrease of pressure. While the height of the excursion was but slightly accentuated after subsequent injections, the time consumed in reaching the maximum height of the pressure was markedly shortened. The cases of hypertension fell into 2 groups which were clinically indistinguishable. In the 1st group no definite change could be ascribed to the 1st injection of adrenalin, while the other cases of marked hypertension responded with a brisk and intense increase of systolic blood pressure. When the test was repeated all the patients with hypertension responded with intense rises of pressure. In cases of early or intermittent hypertension the findings were like those of the former group of advanced hypertension, but less pronounced. Statistically it was found that the ratio of the difference and of the probable error of difference between the standard deviations from the average readings following the 1st and the repeated injections of adrenalin was significant in the 1st group, in those hypertensive patients in whom the response was absent on the 1st injection. The diastolic pressure decreased after all the injections but the time required to return to normal was longer in the patient with hypertension than in the normal person. It was not influenced by repetition of the test. The increase in heart rate and the occurrence of cardiac irregularities were not influenced by the state of hypertension or by repetition of the test. The blood pressure reaction of adrenalin in hypertension did not depend on the level of the blood pressure, the size of the heart, presence or absence of kidney disease, or the level of the blood Ca. No satisfactory explanation could be offered for the absence of response in some individuals with hypertension or for the change in response between 1st and subsequent tests. The clinical adrenalin reaction is not due to peripheral vasoconstriction. In fact a vasodilatation is present which indicates that the systolic rise is of cardiac origin. The intense increase in the patient with hypertension is thought to be related to the general instability of the hypertensive blood pressure. This instability is briefly discussed and considered mathematically.—*Author's summary.*

1287. KAFKA, V. Die Bedeutung der Bestimmung der Eiweissrelation des Liquor cerebrospinalis für die Pathologie der Syphilis. *Dermatol. Wochenschr.* 88(9): 332-335. 2 fig. 1929.—The author calls attention to the need for further study of spinal fluid in syphilis. He reports results obtained by two methods for total protein determination and one each for globulin and albumin. From these he calculated the hydration co-efficient and protein co-efficient. He charts the various findings in normal individuals, syphilis, tabes dorsalis, general paresis, and cerebral syphilis. The protein co-efficient and hydration co-efficient are highest in general paresis. The total protein is highest in cerebral syphilis, in which the total albumin is also highest.—*S. W. Becker.*

1288. KANAI, T., und K. MINAMI. Experimentelle Versuche über die Entstehung der aseptischen und atraumatischen Pleuritis. "Eine Beweisführung für das Wesen der sog. Militärpleuritis und der idiopathischen Pleuritis in Japan." *Zeitschr. Tuberk.* 56(6): 434-444. 1 fig. 1930.—Animals [apparently rabbits: number not stated] were subjected to intravenous injection of various nerve poisons, to various forced motions of the body, to unilateral and total epinephrectomy, to resection of the vagus and splanchnic nerves and to double cervical sympathectomy. The results, the authors believe, furnish a new explanation for the origin of aseptic and atraumatic pleuritis, as the result on the one hand of a disturbance of the neurohormonal correlation produced by artificial crippling of the functions of the locally prevailing vegetative nervous system, and on the other by artificial disturbance of the equilibrium in the distribution of ions in the body fluids, produced by injection of various poisons.

1289. KITAGAWA, KIYOSHI. Über Haematoporphyria congenita Günther. II. und III. *Japanese Jour. Dermatol. & Urol.* 28(8): 771-797. 5 fig.; (9): 851-871. 7 fig. [German summaries 53-54 and 61-62.] 1928.—II. Skin of patients was abnormally oversensitive to sunlight, but hyposensitive to Hg-quartz lamp, so that the kind of rays to be considered as causing porphyrin-sensibilization must be present in the long wave parts of the spectrum. The connection between porphyrin photo-sensibilization and variety of ray was experimentally determined. III. In the photodynamic phenomenon of skin of congenital porphyrin patients there is high grade inflammatory edema of the corium; the epidermis at first is free from injury; blister caused by the insolation appears always in the upper stratum of the corium and is elevated. Rabbit's skin, after the animal is given porphyrin, becomes very hypersensitive to sunlight; after insolation (30 min.) there develops following a certain latent period (12-24 hrs.) severe inflammatory edema of the irradiated skin, and after some weeks atrophy of the skin may follow, even necrosis if the sensibilization is intense. Histologically the epidermis is unaffected, the corium is greatly thickened by severe inflammatory edema. This is in entire accord with the findings observed in the congenital porphyrin patient. The rabbit's skin is also rendered hypersensitive to quartz-lamp light by administering porphyrin, but much more must be injected than for sunlight (usually over .005 gm. per kgm.). Identical skin changes as from sunlight are obtained if the ultraviolet rays of Hg-lamp light are excluded with a glass filter.—*W. Browning.*

1291. KRAUT, HEINRICH, und ERWIN BUMM. Ueber das Co-ferment der Glykolyse aus Tumoren. *Hoppe-Seyler's Zeitschr. Physiol. Chem.* 177(3/4): 125-142. 1928. The particular enzymic part of the glycolytic process which caused the increased lactic acid formation found by O. Warburg in tumors was studied. The glycolytic coferment, whose presence in tumors had been established by N. Waterman, and by H. v. Euler and K. Myrbäck, was therefore determined for human mammary, rectal and gastric carcinomas, Flexner-Jobling rat carcinomas and Jensen rat sarcomas. The tests were made on washed sections of rat kidney, the glycolysis of which was increased by tumor extracts almost up to the level of the tumors themselves. The quantity of lactic acid produced was determined by Warburg's manometric method. Comparisons were made against extracts of kidney and liver tissues which also contained the coferment but in smaller quantities than did tumors. The coferment extracted from the tumors was concentrated to about 125 times by alcohol precipitation and adsorption on clay; it was tested by finding how the glycolysis of fresh liver and kidney sections was influenced by addition of this purified coferment. This study showed that the coferment was the limiting factor for glycolysis by normal kidney and liver tissue. Carcinomatous tissue differed from the latter by its increased content of coferment.—*H. Kraut (transl. by B. Cohen).*

1292. KYLIN, E. Studien über die Ödemausschwemmung. VI. Mitteilung: Über den colloidosmotischen Druck des Blutserums während der Ödemausschwemmung in einem Fall von Myxödem. *Zeitschr. Klin. Med.* 113(2): 317-320. 1 fig. 1930.—The colloid-osmotic pressure sank from supernormal to subnormal values during thyroid treatment, and basal metabolism rose from −30% to normal (+6%).

1293. LEVINE, B. S. Serologic studies by the precipitation, precipitation-fixation and the cold fixation tests for syphilis. *Jour. Lab. & Clin. Med.* 15(10): 985-993. 1 fig. 1930.—Sera (700) were tested for the presence of antigen combining antibody by the Kahn, Kahn-Wassermann combined, and the Kolmer procedures. About 14.5% (100 sera) were positive by 1 or more of the

methods used. The positive values were subjected to statistico-analytic study. It was pointed out that from a theoretic viewpoint no syphilitic specificity can be claimed for any of the laboratory tests for syphilis now in use. Excerpts of histories are presented to show instances in which the Kahn and the Kolmer tests gave positive results, yet the final diagnosis made no reference to syphilis. The following conclusions are drawn: The results obtained by the cold incubation and the Kahn-Wassermann fixation procedures closely agree. The percentage agreement between the Kahn and Kahn-Wassermann, and the Kahn and Kolmer are identical (67.0%). The Kahn yields negative results in about 25.0% of the cases where antigen combining substance is present. The Kolmer and Kahn-Wassermann differed in only 5.0% of the cases. Averaging the 3 readings of the Kahn precipitates to obtain an interpretation of the results is a mistaken procedure.—*Author's summary and conclusions.*

1294. **McCARTNEY, JAMES LINCOLN. Dementia precox as an endocrinopathy.** *China Med. Jour.* 42(4): 278-285. 1928.—The literature in general supports the contention that endocrinopathy is consistently found in dementia precox cases. Eunuchs (23) examined showed typical dementia precox or schizoid characters; good intelligence and orientation, but distinct changes in the effect. Some retained sexual function but no libido. Of 70 live ♂ dementia precox cases examined, at least 60% were eunuchoid in type, only 5.7% having apparently normal testes, with other signs of endocrine dysfunction. However, a large number functioned sexually. Of 40 live ♀ dementia precox cases, 52.5% showed undoubted ovarian pathology, although some had been pregnant. Pathological examination of 158 ♂ and 24 ♀ dementia precox cadavers showed marked endocrine changes. No normal ovaries and only a small percentage of normal testes were found in these cases. Almost every dementia precox individual gave a history of having had 1 or more of the severe toxemias, and at least ¼ of the cases inherited defective somatoplasm.—*Author's summary.*

1295. **NEGRO, FEDELE. Sulla patogenesi dei crampi funzionali. [The pathogenesis of functional cramps.]** *Minerva Med.* 1(13): 536-542. 1930.—From personal clinical observations, and after consideration of the literature, Negro concludes that functional cramps are the expression of a lesion of the extrapyramidal sympathetic nervous system, located primarily in the corpus striatum, particularly the pallidum and the locus niger or the sympathetic-sensory terminations, communicating by a reflex route with the medullary sympathetic centers and thence with the efferent fibers destined to innervate the sarcoplasm; and that in both cases the mechanism consists of a sarcoplasmatic hypertonicity consequent on these lesions. The psychic elements are secondary. The different aspects (paralytic, tremulous, etc.) under which the functional cramps may present themselves do not invalidate the foregoing hypothesis.—*From author's summary.*

1296. **NIELSEN, OTTO JUL. On oscillations of blood-sugar values within brief periods, and the blood-sugar curves on uniform ingestion of glucose.** *Biochem. Jour.* 22(6): 1490-1498. 2 fig. 1928.

1297. **OKA, MITSUTOMO. Experimentelle Studien über die Störungen der Ösophaguspassage. [Disturbances of the esophagus.].** *Proc. Imp. Acad.* [*Tokyo*] 4(7): 430-432. 1928.

1298. **ORIEL, G. H. Some observations on the biochemistry of asthma.** *Guy's Hosp. Repts.* 79(4): 480-490. 1929.—Asthmatics do not fall into one biochemical type. Those whose cases commence as infantile eczema, or are complicated by other allergic manifestations, show a low blood sugar, positive van den Bergh reaction, decreased sedimentation rate, diminished bicarbonate and high amino-acid in the blood during the active stage. In uncomplicated asthma the blood findings are usually a low blood sugar, negative van den Bergh reaction, decreased sedimentation rate during the attack but increased after, and normal amino-acid. The urine shows various changes in both types. A complex nitrogenous substance of a proteose nature is excreted in the urine in the different forms of allergy, which on reinjection gives positive skin tests in many cases. It is suggested that the asthmatic diathesis consists of biochemical instability in nitrogenous and carbohydrate metabolism and in acid-base balance.—*From author's summary and conclusions.*

1299. **PARADE, G. W., und W. STEPP. Über experimentell erzeugte Myokardschädigungen durch Jodinpininjektion in die Herzkammerwandung des Hundes und die dabei auftretenden Veränderungen im Elektrokardiogramm.** *Zeitschr. Klin. Med.* 113(2): 195-211. 14 fig. 1930.—Injection of iodipin into the region of the ramus descendens of the left coronary artery in 6 dogs was followed by a transient hyperirritability of the ventricle, manifested by a high-grade extrasystole. The decided heightening of the T-wave, observed earlier after injuries in the region of the ramus descendens, did not occur immediately after iodipin injection. The coronary T-wave, generally returning to normal in the course of days or weeks, was a late result of iodipin injection in the region of the ramus descendens. The relation which these observations bear to human cardiac disturbances following sudden coronary block is obvious.

1300. **PERONI, ACHILLE. Rapporti fra faringiti secche e solfocianuro potassico salivare. [Relation between pharyngitis sicca and salivary potassium sulphocyanate.]** *Arch. Ital. Otol., Rinol. e Laringol.* 40(10): 644-650. 1929.—The salivas of 55 patients with various kinds of pharyngitis were examined for KCNS, which was found to vary from 0.0295 to 0.0035 gm. per 100 cc. Of the 55 patients, 23 were affected with pharyngitis sicca; among these the KCNS content varied from 0.0190 to 0.0035, being below 0.006 in 18 of them. The fact that in pharyngitis sicca there is a marked atrophy of the pharyngeal mucosa and also a low KCNS content suggests to the author that this salt may be secreted not alone from the salivary glands, but also, and perhaps chiefly, from the mucous and mixed glands, which are specially abundant in the pharyngeal mucosa.

1301. **QUIGLEY, J. P., and J. L. LINDQUIST. Mechanical interference with the circulation as a factor in traumatic shock.** *Amer. Jour. Physiol.* 94(3): 529-530. 1930.—The abdominal aorta was occluded in 4 experiments until the femoral pulse became imperceptible or very weak (for 15, 85, 115 and 127 min.); the thoracic aorta was occluded for 165 min. with a single ligature and with 2 ligatures for 40, 45 and 110 min., and the thoracic vena cava was occluded until respiration ceased (after 25, 45, or 53 min.), all without shock. Light anesthesia with ether previous to such procedures caused marked disturbance or cessation of respiration. The authors suggest that their experiments differ from those previously reported by others in the absence of 2 complicating factors, ether anesthesia and manipulation of the viscera, abdominal or thoracic. They conclude that in the absence of anesthesia or direct trauma, moderately extensive interference with the circulation (arterial or venous) of large portions of the body does not produce traumatic or surgical shock either during or subsequent to such circulatory obstruction. The species of experimental animal used is not stated.

1302. **RICHTER, MAURICE N., and E. C. MacDOWELL. Studies on leukemia in mice. I. The experimental transmission of leukemia.** *Jour. Exp. Med.* 51 (4): 659-673. 1930.—Lymphatic leukemia has occurred with great frequency in a strain of mice inbred by brother-sister matings since 1921. In addition to typical cases of leukemia are others which, because of the absence of leukemic changes in the blood, correspond to "pseudoleukemia" and others which, by the presence of unusually great enlargement of certain lymph node groups, resemble the "leukosarcomatoses" as observed in man. Examinations of the blood of leukemic mice have shown that leukemic blood pictures are not necessarily early in their appearance, nor are they constant. The blood picture may not, therefore, be used as a

criterion for the separation of the two diseases (leukemia and pseudo-leukemia) but merely indicates different phases of the same condition. Likewise, cases with lesions intermediate between the local growths of "leukosarcomatosis" and the more general lymphatic enlargements of leukemia suggest that these conditions differ only in the distribution of lesions but not in their nature. Lymphatic leukemia occurring spontaneously in this strain may be transmitted to other mice of the same strain, and carried, apparently, for an unlimited number of transfers in animals at an earlier age than that at which leukemia occurs spontaneously. In each of 10 such experiments transmissions were obtained. The lesions produced by inoculation correspond to those of spontaneous cases, in that they consist of growths of abnormal lymphoid cells which infiltrate tissues and organs and often appear in the circulating blood. Only minor differences have occurred, some of which are characteristic of certain experimental lines. After repeated transfers, the disease tends to run a more acute course. Among the cases in which transmissions occurred, are some without leukemic changes in the blood, and many with local growths at the site of inoculation or in certain node groups. The differences in the blood pictures and distribution of lesions (which latter may be influenced to some extent by the method of inoculation) correspond to similar differences which are sometimes observed in the spontaneous cases.—*Authors' summary.*

1303. SALEN, E. B., und T. NYRÉN. Klinische Versuche mit der Glykosefixationsprobe (nach Loewi). Eine Nachprüfung gewisser Resultate der Grazer Schule an klinischem Material. *Acta Med. Scandinavica Nord. Med. Arkiv.* 72(2): 167-220. 1929.—On the basis of extensive animal experimentation, the Graz School of investigators reported in 1925-27 an original theory concerning the pathogenesis of diabetes, to the effect that in addition to insulin there occurs another, and, so far as sugar regulation is concerned, more important hormone-like substance secreted by the liver. This so-called "glykemin" is functionally a direct antagonist of insulin and is of fundamental importance in the occurrence of every hyperglycemia. An increased blood sugar, for example, would be due to a primary hyperglykeminemia with relative insufficiency of insulin, or caused by a primary insulin deficiency with secondary hyperglykeminemia. Were it possible through analysis of the peripheral blood to establish a quantitative insulin-glykemia ratio, this would be of great clinical value in differentiating hyperglycemic conditions into groups, namely, the pancreatogenous (insular) and the non-pancreatogenous (extrainsular) types. Such a method was devised by the Graz investigators, and was followed by the present authors, although in the meantime Loewi has retracted some of his original statements and modified his former conclusions. The material for the present study included normal individuals, diabetics, and persons with hepatic disease. Estimations of basal values (that is, glucose determinations on the plasma after a 12-14-hr. fast) were made, as well as fixation and blood sugar curves after feeding various amounts of glucose per os, and after the administration of adrenalin or insulin. It was found that the basal values of normal human beings showed a considerably greater variation than those of the experimental animals reported by the Graz School, and did not justify any conclusions in differential diagnosis. The same was true of the blood sugar curve after the administration of glucose by mouth, and hence, speaks against the correctness of Loewi's theories. Previous experiments reported by the authors as well as by certain French investigators make it appear possible that there is an element of truth in Loewi's theory, but that the facts are of a much more complicated nature than he assumes.—*T. C. Hempelmann.*

1304. SATKE, O. Über den Hydrothorax bei kardialer Insuffizienz. *Zeitschr. Klin. Med.* 113(2): 212-223. 1930.—In 7 out of 8 normal cases studied the negative pressure was somewhat greater in the right than in the left pleural cavity, which apparently explains the clinically well-known fact that in most cases of cardiac insufficiency the right hydrothorax is greater than the left. The occurrence of right hydrothorax as the sole sign of cardiac insufficiency, of which a case is described, is explained as a result of factors hindering the discharge of the vena azygos, such as pressure from a dilated right-auricle, slight pleural adhesions or other conditions apparently promoted by the negative pressure prevailing in the right pleural cavity.

1308. SHORE, R. A., and R. L. ANDREW. Goitre in school-children. The incidence of goitre in school-children in relation to the amount of iodine in soil and water in certain districts of the North Island of New Zealand. 67p., 3 maps. New Zealand Dept. Health & Sci. & Indust. Res.: Wellington, 1929.—The goitre percentages given have been entirely compiled by one worker, so that the "personal error" is the same all through. The analytical work has been done entirely by one worker, so that the "personal error," if any, is again the same all through. The two aspects of the work were done quite independently by the investigators. The field worker did not know the I analysis until the field work was completed, and the chemist did not know the result of the field work until the analytical work was completed. Sufficient samples of soil were taken so that the result would be representative of the district. Similarly, as many school-children as possible were examined in each district. The goitre incidence in school-children is greater in girls than in boys. The percentage incidence in both sexes increases with age to a maximum and then definitely declines. On the figures available, this decline in incidence appears to continue in the years beyond school life at least as far as 19 years of age. The rate of percentage of goitre incidence is increased at or just before the time of puberty. The effect of puberty is more marked in girls than in boys. Generally speaking, where the I content of the soil is high the incidence of goitre is low, and where the former is low the latter is high. There are, however, certain anomalies which at present cannot be satisfactorily accounted for. Further work should be done to solve the problem of these anomalies.—*Authors' summary.*

1309. SONDERMANN, R. Beitrag zur Entstehung, Physiologie und Pathologie des Augendrucks. III. Über die Pathologie des Augendrucks. *Arch. Augenheilk.* 102 (3/4): 453-474. 1930.—[III.] There is a movement of fluid in the anterior chamber which, however, is very slight. The normal content of Schlemm's canal is aqueous. The pressure in Schlemm's canal is somewhat less than in the anterior chamber but higher than in the ciliary veins at their point of exit from the eye. The aqueous leaves the eye through Schlemm's canal and also by way of the capillaries of the anterior surface of the iris. This is brought about in case of Schlemm's canal by filtrative forces whereas the carrying off of aqueous by the capillaries of the iris is due to osmotic forces. The intraocular pressure in inflammations of the anterior segment depends essentially upon the development of the perforating vessels of the sclera in this region, particularly the veins, and also on the conditions of outflow from the anterior chamber. The hypotension of old cyclitic eyes is due to the dilatation of the veins in the anterior portion of the sclera. The capillaries of the normal ciliary body usually show marked constriction of the caliber with increasing age, whereas

other capillaries are usually dilated. In two cases of glaucoma simplex without inflammatory changes the author found well marked degeneration in all the ciliary processes, marked thickening of the pectinate ligaments and relative constriction of Schlemm's canal. These changes may play a definite part in the origin of glaucoma simplex.—*F. H. Adler.*

1310. SPIRO, PAUL. Klinische Untersuchungen über das Calcium-Kalium Gleichgewicht im Organismus. *Zeitschr. Klin. Med.* 110(1): 58-93. 1929.—The determination of Ca was made after Kramer-Tisdal, that of K by a method, which is described. Results: Under normal conditions Ca oscillates between 9.5 and 11.5 mgm. %, K between 17.5 and 22.5 mgm. % in the blood serum, under pathological conditions, the oscillations are not much greater. Potassium augments and Ca decreases in icteric diseases; K increases and Ca diminishes in cardiac and renal decompensation, essential hypertension and non-acidotic diabetes mellitus. Potassium and Ca both increase in acidotic diabetes mellitus, both decrease in pregnancy and with tumors. Potassium alone increases without variation of Ca in vegetative neurosis, gastric and duodenal ulcer, chronic arthritides and arthropathies. The content of K in the corpuscles increases much more than in the serum with cardiac and renal decompensation, essential hypertension, diabetes mellitus, vegetative neurosis, gastric and duodenal ulcer and chronic arthritides. The balance of Ca: K in the blood serum is regulated by mobilisations of the depots; K is partially furnished by the corpuscles.—*F. Bruman.*

1318. CARLSTRÖM, BIRGER. Ueber die Ätiologie und Pathogenese der Kreuzlähme des Pferdes (Haemoglobinaemia paralytica). *Skand. Arch. Physiol.* 61(4/5): 161-224. 1 pl., 7 fig. 1931.—Azoturia usually appears on return to work after a few days' rest. It is characterized by stiffness, lameness or paralysis of the hind leg muscles, excessive sweating, and hemoglobinuria. The etiology is unknown, although innumerable theories have been advanced and are discussed. The author finds that the blood plasma in azoturia is seldom colored and that a spectrum resembling that of hemoglobin is not always present. The osmotic resistance of the erythrocytes is usually normal. In most cases there is an increased amount of hemoglobin in the blood, which depends on increased corpuscular content and not on decrease in blood volume. Hemoglobin and myoglobin can be separated spectroscopically, the latter showing bands similar to hemoglobin but displaced 3-5$\mu\mu$ to the left. This difference in spectra is not a matter of solubility but of chemical constitution. In rabbits, dogs and horses, intravenous injection of muscle juice insufficient in amount to color the plasma, produces hemoglobinuria. If hemoglobin is used, the amount necessary to produce hemoglobinuria is so large that the plasma becomes colored. The author concludes that the reddish color of the urine in azoturia depends on muscle pigment, myoglobin or metamyoglobin. Azoturia is therefore characterized by myoglobinemia and myoglobinuria.—*W. J. Meek.*

1319. CARPANO, M. Hemoprotozoal infections (spirochaetosis and piroplasmosis) of poultry in Egypt. *Union So. Africa Dept. Agric. Pan-African Agric. & Vet. Conf. Pretoria, Papers Vet. Sect.* P. 187. 1929(1930).

Wochenschr.* 46(40): 683-688. 7 fig. 1930.—In 47.5% of all dogs, accessory thyroid, rarely parathyroid glands, appear within the pericardium in the neighborhood of the large vessels, usually the aorta, and without relation to race, age or sex. Similar localizations were not found in other domestic animals. In dogs, von Kaltenbock found subendocardial thyroid glands in the conus arteriosus. Since they display normal functioning thyroid and parathyroid tissue they merit consideration by experimental research on the functions of the thyroid and parathyroid and also of other organs of internal secretion. Through goitrous disease they acquire pathological significance. The causes which lead to the origin of these glands within the pericardium of dogs, but not in other animals, still require explanation.—*Author's summary (transl. by E. H. Boyer).*

1328. **EASTERFIELD, T. H., and J. A. BRUCE. The occurrence of xanthin calculi in New Zealand sheep.** *New Zealand Jour. Sci. & Tech.* 11(6): 357-361. 3 fig. 1930.—Calculi, which, according to chemical tests, would seem to be composed largely or wholly of xanthin, are reported in sheep in a few localities (all on "Moutere loam" soil) in New Zealand. Their occurrence and distribution are believed to be related to mineral deficiency in that soil.

1329. **EASTERFIELD, T. H., T. RIGG, H. O. ASKEW, and J. A. BRUCE. A widespread occurrence of xanthin calculi in sheep.** *Jour. Agric. Sci.* 19(3): 573-585. 5 fig. 1929.—Sheep with xanthin calculi in the kidney pelvis were found in 8 localities in Nelson province. A single calculus from 1 sheep weighed 41 gms.; 63 gms. of xanthin were removed from the 2 kidneys of another sheep. On 1 farm, 8% of the sheep died in 1 season from the trouble. All cases occur on Moutere Hills type of soil, which is very deficient in lime and phosphate; no cases have been reported from farms on which good pastures have been established by attention to this deficiency. A report on the organs of the affected sheep is given.—*T. H. Easterfield.*

1330. **EMMEL, M. W. Peritoneal tumors in the fowl.** *Jour. Amer. Vet. Med. Assoc.* 32(1): 99-102. 1 fig. 1931.—The origin of such tumors in some instances appeared to be in the mesothelium, the egg-yolk no doubt being the exciting factor. In another bird the origin may have been in the subepithelial lymph channels. However the tumors arise, both regions may apparently finally become involved.

1331. **FULTON, J. S. The incidence of swamp fever in Saskatchewan in relation to soil type.** *Jour. Amer. Vet. Med. Assoc.* 30(2): 157-164. 1930.—The observation is made that outbreaks of swamp fever never occur on heavy clay lands, while isolated cases occur on light sand or gradation types between very heavy clay and sandy soil, and frequent cases occur on soil varying from sandy to heavy loam. It is further observed that waters in clay soils are decidedly alkaline from early spring until freeze up, while slough waters in loam areas exhibit rank growth and a change, as the season advances, from alkaline to neutral and to acid, depending on rainfall. It was found that swamp fever cases begin to appear when temp. of the sloughs become suitable for growth of microorganisms and when the pH is 7.0-7.6. Spirochaetes were found in ponds, where there was considerable vegetable growth, whenever the reaction was not far from neutral; they were never found in the decidedly alkaline ponds in the non-swamp-fever area. The author does not suggest spirochaetes as the cause, but deems it pertinent that the presence or absence of "that" capable of producing swamp fever coincides with the reaction of the water determining the presence or absence of spirochaetes. Reference is made to the similarity of spirochaetal jaundice in miners.—*F. Volkmar.*

1338. **HOPKIRK, C. S. M., and D. A. GILL. Arthritis in lambs in New Zealand.** *Vet. Rec.* 10(40): 919-923. 1930.—An arthritic condition affecting the limb joints of New Zealand lambs is discussed. The cause is shown to be infection of the joints by an organism of the diphtheroid group. On inoculation into the circulation of sheep it appears to have a predilection for the joints. Reasons are given for believing that infection occurs naturally through docking and castration wounds. Prevention by use of antiseptic methods at time of operation and provision of clean pastures while the wounds heal, is advocated. The organism is very similar to *Bacillus erysipelatis suis* and may perhaps be identical, though swine erysipelas is entirely unknown among pigs in New Zealand. The organism is provisionally named *Corynebacterium* **osteoarthritidis ovis** (p. 923).—*Authors' summary.*

1363. **SCHLOTTHAUER, CARL F.** The incidence and types of disease of the thyroid gland of adult horses. *Jour. Amer. Vet. Med. Assoc.* 31(2): 211-218. 6 fig. 1931.—The thyroid glands of 100 horses were studied grossly and microscopically. The data obtained indicate that any gland having a wt. greater than 0.66 gm. for each kgm. of body wt. is abnormal. However, smaller glands may also show pathologic changes. Of 100 thyroid glands studied, 34 were classified as normal, 20 as hyperplastic, 9 as colloid, and 37 as adenomatous. The adenomas were benign papillary, fetal and colloid; none were malignant. Sex apparently is of no significance. The youngest animal having an adenomatous gland was 10 yrs. old. Approximately 40% of horses having adenomatous thyroid glands were in poor general condition, whereas only 17% in the 3 other groups were thus classified. This may indicate that some adenomas impair the health of the horse.—*Author's summary.*

1364. **SCHMIDT, FRITZ.** Rotlauferkrankungen bei Vögeln im Anschluss an Schweinerotlauf und Mäusesep-

tikämie. *Deutsche Tierärztl. Wochenschr.* 39(13): 196-198. 1931.—The author reports 2 epizootics of erysipelas in poultry and other birds at a zoological garden, in which a direct relation was demonstrated with swine erysipelas and with mouse septicemia respectively.

1365. **SIMMS, B. T., C. R. DONHAM, and J. N. SHAW.** Salmon poisoning. *Amer. Jour. Hyg.* 13(2): 363-391. 1931.—Salmon poisoning is a disease of Canidae associated with infestation with the intestinal fluke *Nanophyetus salmincola* Chapin. The flukes reach maturity in 5-7 days after the metacercariae are swallowed by a suitable mammalian host. Eggs hatch in 60-80 days. The snail host is *Goniobasis plicifera* var. *silicula* (Gould). The fish hosts include the species of both salmon and trout occurring in western Oregon. The mammalian hosts include dogs, foxes (both blue and silver black), coyotes, raccoons, bobcats and minks. There is no evidence that this parasite is lethal to the snail host. Fish tolerate very severe infestations. Of the mammalian hosts the Canidae only have developed the disease. The specific cause of salmon poisoning is unknown. The disease has a definite incubation period, followed by typical acute symptoms, and high mortality. Significant pathological lesions are limited to the digestive tube. No satisfactory medicinal treatment has been found. Recovery is followed by a definite immunity. The intraperitoneal injection of mature flukes results in symptoms similar to those produced by eating parasitized fish. Attempts at producing immunity have been unsuccessful.—*Authors' summary.*

Chir.* 9(10): 949-975. 1930.—Anaphylactic shock was induced in 9 rabbits and 7 dogs and the antipeptic and antirennin indexes of the blood were determined at various times thereafter. While there was no change in blood antiferments immediately after production of shock, 12 hrs. afterward there was a marked fall in both antipeptic and antirennin indexes. It is concluded that anaphylaxis may be instrumental in producing gastric ulcer, through both the vascular changes and the fall in blood antipeptic and antirennin indexes.

1378. **ANAN, SHINJI.** Über die Schwankung des Kalk- und Kaliumspiegels im Blute bei der Serumanaphylaxie sowie bei dem Histamin- und Peptonshock. [In Japanese.] *Nagasaki Igaku Kwai Zasshi* 5: 751-762. 1927.—In the blood of guinea pigs the Ca level rises distinctly in serum anaphylaxis and rises in the same

way during histamine or peptone shock. This rise in calcium is seen to a less extent in rabbits. As far as these observations go, it may be concluded that anaphylaxis and peptone or histamine shock fall within the same category.—*J. M. Watt.*

1379. ANDO, K., and H. NISHIMURA. On the heat stability of the diphtheria toxin. *Jour. Immunol.* 19 (5): 465-471. 1930.—The heat sensitiveness of diphtheria toxin depends on its own pH; the more acidified the toxin, the more heat-stable it is. It is practically destroyed by heating to 80-90° C. for 30 min., but not completely even by boiling for 30 min. When acidified to pH 2.0 prior to boiling, about 1/1000-1/700 of its original toxicity remained after boiling for 30 min. Accordingly, the property of heat sensitiveness accepted hitherto as such must not be considered as a general characteristic of bacterial exotoxins.—*Authors' conclusions.*

1380. ANDO, K. Studies on the "toxins" of hemolytic streptococci. VII. Observations on the titration of scarlet fever toxin. *Jour. Immunol.* 20(1): 1-16. 1931.—Dick toxin, usually stable, deteriorates under some unknown conditions. Dried toxin may retain full potency for a long time. The nucleoprotein content of Dick toxin should be determined in addition to the skin test units, as the nucleoprotein causes confusing results. A dried purified toxin, free from nucleoprotein, is recommended as a standard toxin. A qualitative difference between various toxins exists; this indicates the need for further comparisons of the potency and antigenic activity of various toxins before adoption of an international standard.—*L. A. Barnes.*

1381. ANDREWES, C. H. The immunological relationships of fowl tumors with different histological structure. *Jour. Path. & Bact.* 34(1): 92-107. 1930.—6 fowls bearing the slowly growing fibrosarcoma MH1 were found to have in their serum neutralizing properties active against filtrates of Rous sarcoma No. 1, which is histologically distinct from it. These sera would also neutralize filtrates of fowl endothelioma MH2. Similar neutralizing properties were found in the serum of only 2 of 38 supposedly normal fowls. Birds bearing Rous sarcomata or MH2 endotheliomata may develop some neutralizing antibodies against the Rous virus in their sera, but the appearance of the neutralizing properties is far from constant. The suggestion is made that the active agents of the Rous spindle-celled sarcoma, the MH1 fibrosarcoma and MH2 endothelioma may have some antigen in common. It has not so far been found possible, with the sera active against the Rous virus, to neutralize the virus of the histologically very similar Fujinami fowl sarcoma.—*C. H. Andrewes.*

1382. ARCHIPOW, K. S., und A. J. RABATJUSCHKOW. Der Tetanusantitoxingehalt des normalen Pferdeserums und seine Einwirkung auf die Immunisierung mit Starrkrampfantigen. *Zentralbl. Bakt. I. Abt. Orig.* 118(7/8): 425-429. 1930.—Tetanus antitoxin in exceedingly small amounts was found in the serum of 16 normal horses investigated; these normal sera, given not later than 24 hrs. after intraperitoneal injection of tetanus toxin, protected guinea pigs against local tetanus. No parallel was found between the capacity of a horse serum to form tetanus antitoxin and its capacity to form diphtheria antitoxin.

1383. ARONSOHN, HANS GERHARD. Ueber Untergruppen der Blutgrupp[illegible] A des Menschen. *Zeitschr. Immunitätsforsch.* 64(5/6): 418-440. 1929.—The author confirms the investigations of Landsteiner and collaborators as to the determination of the subgroups of group A by the aid of special human sera. Agglutinin α^1 was found in 11 instances and agglutinin α^2 but once in 69 sera of group AB. Lysins differentiating the 2 subgroups could not be demonstrated, nor could the author differentiate the 2 sorts of cells by use of immune agglutinins.—*P. Levine.*

1384. ARRIGONI, R. Valore complementare nel siero di sangue di bambini in rapporto alle irradiazioni ultraviolette e alla somministrazione di alimenti irradiati. [Complement value of blood serum of infants in relation to ultraviolet irradiation and administration of irradiated foods.] *Riv. Clin. Pediatr.* 28(8): 670-687. 1930.—Gains in complement value of serum and in general conditions were observed in 8 infants under ultraviolet irradiation, in 4 fed irradiated rice water, and in 1 fed irradiated cereal, as compared with that of an unspecified number of non-irradiated infants.

1385. ARTHUS, MAURICE. Les anavenins. Destruction de la toxicité des venins par le formol. *Jour. Physiol. et Path. Gén.* 28(3): 529-543. 1930.—When incubated at 38° C. with 1% formaldehyde, the toxicity of cobra venom is progressively destroyed, as shown by loss of paralytic, proteotoxic and anticoagulant properties. In 0.1% venom solutions, a flocculation is seen after addition of formaldehyde; this may be prevented partly by addition of glycine, and completely by gelatine or by glycerol. Formaldehyde has similar actions on other snake venoms.—*W. R. Fearon.*

1386. ARTHUS, M. Les anavenins. 2 Mémoire. Immunisation par les anavenins. *Jour. Physiol. et Path. Gén.* 28(4): 773-788. 1930.—After formaldehyde treatment, snake venoms, notably cobra venom, are rendered harmless, and at the same time capable of conferring some immunity on the inoculated animal (rabbit). The term "anavenin" is applied to these detoxicated venins, and it is shown that their antigenic effect is not due to traces of unchanged venin as an impurity.—*W. R. Fearon.*

1387. ARTHUS, M. Les anavenins. 3. Mémoire. Anaphylaxie engendrée par les anavenins. *Jour. Physiol. et Path. Gén.* 28(4): 800-815. 1930.—Anavenins are capable of sensitizing animals so that they react anaphylactically to the original venin and to other physiologically related venins.—*W. R. Fearon.*

1388. ASCIONE, GUGLIELMO. Influenza delle sostanze proteiche sulla produzione di anticorpi. I. [Action of proteins on antibody formation.] *Boll. Soc. Ital. Biol. Sperim.* 5(6): 1038-1041. 1930.—Serum albumin of ox, injected into rabbits after injection of typhoid or staphylococcus vaccine, exerts no influence on specific agglutinin production. Injection of ox serum globulin is followed by diminished production of antityphoid agglutinins, while formation antistaphylococcic agglutinins is greatly increased.—*M. Comel.*

1389. ASCIONE, GUGLIELMO. Influenza delle sostanze proteiche sulla produzione di anticorpi. II. [Action of proteins on antibody formation.] *Boll. Soc. Ital. Biol. Sperim.* 5(6): 1042-1045. 1930.—No marked variations in agglutinin content of serum occurred in rabbits into which, together with paratyphoid, a vaccine, milk albumin or ox serum globulin were injected. On the contrary, a marked increase of agglutinins followed administration of serum albumin.—*M. Comel.*

1390. ASHBY, W. R. O agglutinins in enterica carriers. *Jour. Path. & Bact.* 34(1): 109-110. 1930.—The agglutinin titers of seven typhoid carriers for H and O suspensions are recorded.—*A. E. Boycott.*

1392. BAAR, HEINRICH, und HANS BENEDICT. Zur percutanen Immunisierung mit der Löwensteinschen Diphtherieschutzsalbe. *Zeitschr. Kinderheilk.* 50(2): 195-211. 1930.—Since production of tetanic antitoxin in horses can be increased by local inflammation at point of injection, this action was tested with Löwenstein's diphtheria ointment. 4 groups of 6 guinea pigs each were used, the shaved skin of the 1st being irritated with mustard oil, of the 2nd with turpentine, the 3rd was not irritated, the 4th was used as control. The ointment was applied twice at an interval of 14 days. The skin irritated with mustard oil showed immunity to intracutaneous and subcutaneous injection of diphtheria toxin. The other guinea pigs showed no immunity. Clinical experiments with 110 children gave 62.27% — Schick reactions before using a mustard plaster (instead of oil); with hyperemia, 80.2% — reactions were obtained.

The diphtheria morbidity curve in the hospital was favorably influenced by percutaneous prophylaxis. ¼ of the children were Schick + after 2 yrs., but in most cases a single percutaneous application rendered them again Schick-negative.

1393. BANZHAF, EDWIN J., and A. J. KLEIN. A practical method for concentrating chill free pneumococcus antibodies from sera without use of salt precipitations. *Proc. Soc. Exp. Biol. & Med.* 28(3): 276-278. 1930.

1394. BANZHAF, EDWIN J., and THEODORE J. CURPHEY. A modified method for the production of antipneumococcus serum in horses. *Proc. Soc. Exp. Biol. & Med.* 28(3): 279-280. 1930.

1396. BARBEY, EDMOND. L'amygdale palatine et le système réticulo-endothelial. *Acta Oto-Laryngol.* 15 (2/4): 210-222. 1931.—The author repeatedly injected various pigments into the ear veins of 6 rabbits (india ink into 2, lithium carmine into 2, electrargol into 1, trypan blue into 1), and killed them 6-224 hrs. after the last injection. The usual localization of pigments was obtained for the liver, spleen and lymphatic ganglia. The tonsils of the rabbit treated with trypan blue showed a few colored cells; those of 1 of the 2 treated with lithium carmine, a very few colored cells; the others were clearly negative or doubtful. Since vital staining shows up reticulo-endothelial cells, it is concluded that the tonsils of rabbits contain some, but very few, reticulo-endothelial elements, which therefore under normal conditions play an altogether secondary rôle.

1397. BARNES, M. F. The Drummond pipetting machine. *Jour. Amer. Vet. Med. Assoc.* 31(2): 240-241. 1 fig. 1931.—This machine was found satisfactory in serum-test work.

1398. BENEDEK, T. Über immunobiologische Vorgänge bei der Schizosaccharomykose (Spalthefemykose). [Immunobiological processes in schizosaccharomycosis (fission yeast mycosis).] *Acta Dermato-Venereol.* 9(1): 76-97. 1928.

1399. BENJAMINS, C. E., et B. S. VERMEULEN. Recherches sur les substances sensibilisantes qui provoquent le rhume des foins, au moyen de la méthode de Dale. *Acta Oto-Laryngol.* 15(2/4): 121-141. 1931.—Of 57 guinea pigs sensitized by intraperitoneal injection of pollen extract of 7 grasses, 36 gave a positive reaction by the Dale method, the ratio of number tested to number of positive results being for the various grasses: rye (*Secale cereale*), 15: 13; creeping soft grass (*Holcus mollis*), 9: 2; red fescue (*Festuca rubra*), 4: 3; crested dogstail (*Cynosurus cristatus*), 2: 1; meadow foxtail (*Alopecurus pratensis*), 8: 6; timothy (*Phleum pratense*), 4: 2; cocksfoot (*Dactylis glomerata*), 15: 9. The sensitization was specific for each of the species tested. Rye pollen contains a more specific, very active, histamine-like substance which produced contractions of smooth muscle in 44 of 51 guinea pigs on a grass-free diet and in 36 of 41 on a grass diet. Food allergy by ingestion of grasses was established: of 33 guinea pigs on a hay diet, 15 gave a positive reaction to pollen extract of 1 or several grasses, while of 51 kept on a grass-free diet, none reacted positively.

1400. BERGEL, S. Über pathologische Lipoidbildung bei der experimentellen Syphilis und ihre Beziehung zur Wassermannschen Reaktion. *Arch. Dermatol. u. Syph.* 161(1): 220-231. 4 fig. 1930.—The author previously demonstrated that the spirochaete cell membrane consists essentially of a lipoid, which chemotactically produces a lymphocytic reaction, which in turn by its lipolitic power brings about a disintegration of spirochaete. He sought then to answer experimentally the question as to whether one can detect in syphilitic tissue, pathological lipoid formation playing a rôle in the Wassermann reaction. He had previously produced a positive Wassermann by injections of nonspecific lipoid. Rabbit syphilomas in various stages were now studied by the usual methods for staining fat and lipoid, and pieces of the same tissues were treated by Levaditi's method to establish the relationship between spirochaetal content and lipoid formation. In areas of induration of the testicle tunica there were found in the connective tissue cells, in the so-called histiocytic elements, and very strikingly in the walls of the lymph- and blood-vessels, granules and droplets stained red with sudan (intra- and sometimes extracellularly) in the same tissues favored by the spirochaetes, as shown by the Levaditi preparations. These pathological lipoids act as antigen and produce a walling off and penetration by lymphocytes, in the wake of which comes a gradual dissolution and disappearance of lipoidal substances. Also the biological rule advanced by the author was confirmed that lipoids of exogenous and endogenous origin produce a lipolytic lymphocyte reaction, by which the antigen is destroyed. It seems reasonable to consider that a sort of toxic action of the spirochaete is responsible for production of the lipoid formed in approximately the same locations. The author does not believe that reticulo-endothelial cells are originators of antibodies against the spirochaete, but that they are merely containers and breeding places for the spirochaetes. The active defense reaction begins only after lymphocytic infiltration has set in. Results also elucidate the question, as to whether this lipoid formation has a relation to the Wassermann reaction. Using serum of testicular lesions rich in lymphocytes, the author obtained in rabbits a positive Wassermann reaction with luetic fetal liver and with cholesterinized beef-heart extract. He believes that the "reagins," antilipoids in the local products of disease, are produced by lipolytic lymphocytes which appear as a reaction against lipoidal antigens, and are thence poured into the blood. In accord with this are the facts that in man also, a positive Wassermann can be demonstrated in serum from primary lesions and from regional lymph glands, as well as in serous cavity fluid, in joint fluid and in cerebrospinal fluid of sphilitics even when the reaction is still negative in the blood. From these investigations the cycle seems to be: Syphilis spirochaetes, lipoidal metabolic disturbance, chemotactic lymphocyte infiltration, antilipoid formation, and positive Wassermann reaction. It is apparent that the latter is constructed from 2 components: (1) antibody against spirochaetal lipoid, in which the amboceptor-like lipase arising from the lymphocytes combines with spirochaetal lipoid and is activated by complement contained in the body fluids, and (2) antisubstances against the pathological lipoid, which likewise are formed from lymphocytic reaction products. Lymphocyte lipase also acts almost specifically on 2 lipoids, as the author demonstrated in the hemagglutination and hemolysis of 2 different kinds of erythrocyte lipoids.—*From author's summary (transl. by H. E. Meleney).*

1401. BLACHER, W. Ein kasuistischer Beitrag zur Aktivierungshypothese der postvakzinalen Erkrankungen (Vakzination und Tuberkulose). [A casuistic contribution to the activation hypothesis of postvaccinal diseases (vaccination and tuberculosis).] *Jahrb. Kinderheilk.* 130 (3/4): 201-209. 1931.

1402. BLANCHARD, E. W. An experimental study of the opsonins of the blood. I. Effect of bilateral adrenalectomy. *Physiol. Zool.* 4(2): 302-315. 1931.—Cats were operated upon by the same individual, and the 2 adrenal glands were removed separately. They completely recovered from the 1st operation before the 2nd gland was removed. Operated animals were bled at frequent intervals and the opsonic activity of the blood was determined. Serial dilutions of experimental and of normal serum were made. Collodion particles were used as "antigen." Cat leukocytes were obtained by intraperitoneal injection of 0.9% NaCl and subsequent withdrawal of peritoneal exudate. These cells were washed and suspended in isotonic NaCl. 1/10 cc. each of serum or its dilution, of collodion suspension and of

leukocytes were mixed in small tubes corked and agitated slowly for 15 min. After spreading and staining, the opsonic activity in terms of % of phagocytic cells was determined. Results show clearly that the opsonin content of the blood begins to drop about 2 days after removal of the 2nd adrenal gland. The experimental cats lived, on the average, about 7 days, and during the terminal stages of adrenal deficiency the drop in opsonic activity was very marked. Double-nephrectomized cats, showing symptoms similar to those of adrenal insufficiency, were bled, and their blood showed no change in opsonic activity, even at the terminal stage.—*Author (courtesy Wistar Bibl. Serv.).*

1403. BLANCHARD, E. W. An experimental study of the opsonins of the blood. II. Effect of irradiation with ultraviolet and with x-rays. *Physiol. Zool.* 4(2): 316-323. 1931.—Normal cat serum, after being separated from the cells, was divided into 2 parts: (1) was irradiated with ultraviolet or x-rays; (2) served as control. A Hanovia mercury-arc lamp was used as source of ultraviolet; a Coolidge tube, running at 65 kilovolts at 6-7 milliamperes, as source of x-rays. The serum was exposed 10 in. from the ultraviolet lamp and 12 in. from the target of the x-ray tube. The temp. factor was controlled in all experiments. Accurate serial dilutions of the sera were made, and the opsonic activity of the experimental and control sera was determined by the method previously outlined. Exposures of various times were made. The opsonin is almost completely inactivated by a 30-min. exposure to ultraviolet or by a 45-min. exposure to x-rays. Shorter exposures markedly decrease the opsonic activity of the blood serum.—*Author (courtesy Wistar Bibl. Serv.).*

1404. BLOCH, BRUNO, und A. STEINER-WOURLISCH. Die Sensibilisierung des Meerschweinchens gegen Primeln. *Arch. Dermatol. u. Syph.* 162(2): 349-378. 9 fig. (2 col.) 1930.—By 1 or more cutaneous applications (or by intracutaneous, and slightly by intracardial injections) of the concentrated ether extract of primroses, it was possible to sensitize 41 of 43 guinea pigs against the dilute (1-5%) extract antigen of primroses, which did not affect a normal animal. This allergy was expressed as an inflammatory reaction of the skin, appearing first as a very acute, vesicular eczema that later took a more chronic course. The incubation time to appearance of allergic reaction was 2 hrs. to 1 day, the reaction usually lasting 2-6 or more days. The allergy extended over the entire body; focal reactions were also seen. It was possible to sensitize with the extract against primin, the pure crystallized extract from primroses, and vice versa. Attempts to transfer the allergy to other guinea pigs or to rabbits were negative in the 10 instances tried. Negative also were attempts to desensitize by repeated cutaneous application of concentrated extracts.—*From authors' summary (transl.).*

1405. BLUMENTHAL, G., und E. NASSAU. Zur Diphtherieimmunisierung mit der Schutzsalbe von Löwenstein. *Zeitschr. Kinderheilk.* 50(6): 742-747. 1931.—3 applications of 1 tube (3 cc.) each were made on the shaved skin of each of 5 rabbits at 14- and 7-day intervals; on the 49th day the titer in all animals (1 died intercurrently) was less than 1/100 antitoxin units. 2 applications were given 157 children with a 10-12-day interval. The favorable clinical course (1 child, attacked 5 days after 1st inunction and not attributable to unsuccessful treatment) was contrary to the outcome of the Schick test (35%+) and determination of antitoxin in the blood. With 1 exception, attributable to other causes, no rise in antitoxin was found in 29 children, even when a certain antitoxin titer was present before treatment. When epidemiological observation is inadequate, biological reactions should also be tested to determine immunological results with antidiphtheritic substances.

1406. BOGENDÖRFER, L. Üder den Einfluss des Zentralnervensystems auf Immunitätsvorgänge. III. Beziehungen des Sympathikus zum Zustandekommen der Agglutination. [Influence of the central nervous system on immunity processes. Relation of the sympathetic system to production of agglutinins.] *Arch. Exp. Path. u. Pharmakol.* 133(1/2): 107-110. 1928.

1407. BORGHI, BRUNO. Effetti dell'iniezione di leucociti omologhi ed eterologhi negli animali. [Effects of injection of homologous and heterologous leucocytes.] *Boll. Soc. Ital. Biol. Sperim.* 5(3): 396-399. 1930.—Homologous leucocytes were injected into rabbits after staining by neutral red; they disappeared from the blood stream after 1 hr. and were to be found thereafter only in lungs and spleen. A destruction of leucocytes in the tissues is suggested. Leucocytosis rarely followed in injected animals; more frequently a modification of the leucocyte ratio was observed. In the bone marrow an increase of leucocytes and megacaryocytes was observed. Pulp hypertrophy was shown by the spleen. When heterologous leucocytes were injected (rabbit blood to mice) the same effects were observed as with homologous leucocytes, with more marked histological modifications; stimulation of the reticulo-endothelial system was followed by a myeloid proliferation of reticulohistiocytes.—*M. Comel.*

1408. BORGHI, BRUNO. Modificazioni umorali consecutive all'iniezione di leucociti. [Humoral modifications following injection of leucocytes.] *Boll. Soc. Ital. Biol. Sperim.* 5(3): 399-400. 1930.—When serum of a rabbit treated previously with injections of leucocytes is injected into the ear lobe of a non-treated rabbit, at this point a greater quantity of leucocytes is attracted than when normal serum is injected. The same result was observed after injecting rabbit serum into the testicle of guinea pig.—*M. Comel.*

1409. BOSSA, G. Ricerche sperimentali sulla reazione emoclasica del d'Amato nelle infezioni tifoidi e nell' infezione melitense. [Experimental studies on d'Amato's hemoclastic reaction in typhoid and undulant fevers.] *Rif. Med.* 45(7): 211-220. 1929.—When rabbits are sensitized to *Bacillus typhi, B. paratyphi* or *B. melitensis*, injection of homologous vaccine at a dosage of 10-40 milliards per kgm. wt. induces a typical hemoclastic shock. When the dosage is kept below these amounts, no shock follows, even in sensitized animals. When the dosage is above these amounts, the reaction may be induced also in non-sensitized rabbits. It does not appear when the agglutinant power of the serum for the bacteria by which the sensitization is produced has reached rather high values (1: 700-800). The specificity is an absolute one for *B. typhi, B. paratyphi* and *B. melitensis;* but animals sensitized to *B. paratyphi A* react as well also to *B. paratyphi B,* and vice versa.—*M. Comel.*

1410. BRANDT, ROBERT. Zur Standardisierung der Mastixreaktion. *Zeitschr. Immunitätsforsch. u. Exp. Therap.* 65(3/4): 221-239. 1930.—Through variation in the concentration of mastic and the degree of alkalinization and by a process of double preparation, an attempt was made to endow the mastic reaction with a high degree of exactness. That this was accomplished is shown by the results of comparative tests on fluids from a single source and by comparisons with gold curves. The details of preparation and use of the "standardized mastic reaction" are given.—*N. W. Larkum.*

1411. BROWN J. C., and H. C. BROWN. Further observations upon electric charge in its relation to haemolysis and phagocytosis. *British Jour. Exp. Path.* 11: 305-310. 1930.—The amount of complement fixed by sensitized bacteria is shown to depend on the concentration of NaCl present. It was thought that an inhibition of serum hemolysis should be obtained in vivo by administering salts with polyvalent anions along with a hemolytic serum, but when trisodium citrate was used there was no evidence of such inhibition. This is probably due to the rapidity with which the citrate is converted into carbonate and eliminated. On the other hand, potassium ferrocyanide, which inhibits serum hemolysis in vitro, also exerts a protective action in vivo when administered to mice together with a dose of hemolytic serum. This salt also markedly interferes with phagocytosis of bacteria; its action is shown not to be due to a destructive effect either on hemolytic ambo-

ceptor or on phagocytes. It is considered that all the effects described are dependent on the relative electrical charges of the reacting components.—*J. Bland.*

1412. **BUADZE, SEVERIAN.** Über das Wesen der Abderhaldenschen Reaktion. *Fermentforschung* 9(3/4): 362-374. 1928.—This research was undertaken to ascertain to what extent the Abderhalden reaction is to be regarded as a complement fixation reaction in the Bordet-Gengou sense. Applying the method adopted, no support was obtained in any of the cases investigated, for acceptance of the complement fixation theory. The opinion expressed by the older authors on the amboceptor nature of the substances concerned in, and the importance of complement for, the Abderhalden reaction, cannot, therefore, be accepted.—*Author's summary (transl. by R. T. Hewlett).*

1413. **BUNNEY, WILLIAM EDWARD.** A new diluent for diphtheria toxin in the Schick test. *Jour. Immunol.* 20(1): 71-84. 1931.—A 2% solution of peptone (Difco-"Proteose"), containing 0.85% NaCl, adjusted to pH 8.4, autoclaved and made to contain 0.5% phenol was found to maintain the toxicity of certain diphtheria toxins diluted to ¼ M.L.D. per cc., under ordinary conditions for periods long enough to permit warranting no loss of toxicity in 2 months. Schick tests done with toxin so diluted gave satisfactory results in children whether or not they had received toxin-antitoxin 6 months previously, and in adults who had not received toxin-antitoxin.—*W. E. Bunney.*

1414. **BURNET, F. M.** Shwartzman's phenomenon of local skin reactivity to bacterial products. *Jour. Path. & Bact.* 34(1): 45-60. 1 pl. 1930.—The effective substance is common to widely different species of bacteria.—*A. E. Boycott.*

1415. **CASTOLDI, FRANCO, e ANNIBALE MACCHI.** La vaccinazione antitubercolare col B.C.G. per via orale. Ricerche sperimentali nei conigli e nelle cavie. [Experimental oral antituberculer vaccination by BCG in guinea pigs and rabbits.] *Arch. Ist. Biochim. Ital.* 2(2): 307-340. 10 fig. 1930.—Following oral vaccination by BCG, health and development were normal as compared to controls. Processes of tissue reaction are determined in the lymph glands. Experimental infection by Calmette's method provoked death in vaccinated as well as in control animals, those vaccinated, however, showing greater resistance. When inoculated through eyes or mouth, alterations were more circumscribed and limited, and reactive processes more intense in vaccinated than in control animals; the latter showed more acute and generalized symptoms. When inoculated through the peritoneum, no difference was evident between vaccinated and non-vaccinated animals.—*M. Comel.*

1416. **CEREDI, A., e A. SERVICI.** Sul potere battericida verso il bacillo tifico di sieri normali e durante lo stabilirsi dell'immunità. [Bactericidal power against typhoid bacilli of normal sera and of sera during development of immunity.] *Boll. Soc. Ital. Biol. Sperim.* 5(3): 361-368. 1930.—A demonstration is offered of the existence of normal bacteriolysins in serum, and their intervention as necessary factors in the bactericidal power of fresh serum. During development of immunity by means of antityphoid vaccination, a stage of diminution of bactericidal power is followed by its specific increase.—*M. Comel.*

1417. **CHUAN, FAN, and C. E. LIM.** Titration of diphtheria toxin and antitoxin on hamsters. *Proc. Soc. Exp. Biol. & Med.* 28(3): 226-228. 1930.—Experiments are reported which demonstrate that hamsters (*Cricetulus griseus*) may be used. This is of importance in countries (e.g., China) where guinea pigs are difficult to obtain.

1418. **CIAMBELLOTTI, E.** Dell'allergia cutanea antitubercolare: a proposito di un caso di tubercolosi miliare con efflorescenze cutanee a tipo di tuberculide papulonecrotica. [Cutaneous antituberculous allergy: a case of miliary tuberculosis with cutaneous efflorescence of the papulonecrotic type.] *Gior. Ital. Derm. e Sifil.* 71 (2): 390-417. 1930.—No tubercule bacilli were found in a cutaneous tuberculid. The author infers that the bacilli had been destroyed and that the skin disease was due to the effect of the death rather than of the life of the microörganism. Since in the anaphylactoid forms, as in allergy, antigen (as the author shows) is disintegrated, it follows that allergy is not so much hypersensitivity as heightened defense against microörganisms and toxins.—*Author's summary (transl.).*

1419. **CITELLI, SALVATORE.** Sui risultati attuali della mia cura nei tumori maligni umani (con presentazione di 5 infermi.) VI. [Results of treatment of malignant tumors.] *Atti Accad. Gioenia Sci. Nat. Catania* 15(Mem. 2): 1-6. 1927.—The author states that by intravenous injection of autogenous vaccines the great majority of patients make a remarkable improvement and sometimes are cured unless treatment has started too late. He presented to the Academy 5 patients treated by him. 2 were cured cases of endothelial sarcoma,—one of 4 and the other of 9 months. 2 were of a sarcoma which had recently disappeared as a result of treatment and another of a carcinoma which had disappeared 4 months previously. Other cases treated by himself and by others are discussed. From the data at hand he believes his method superior to others.—*S. Citelli (transl. by P. Hillkowitz).*

1420. **CLEMENTI, A., e F. CONDORELLI.** Nuove proprietà biochimiche dei pigmenti biliari. III. Potere agglutinante della bile sugli stromi degli eritrociti emolizzati. [Agglutinating power of bile on the stroma of hemolyzed erythrocytes.] *Boll. Soc. Ital. Biol. Sperim.* 5(5): 748-750. 1930.—Bile exerted an agglutinating action on the hemolyzed erythrocytes of some animals, but varied according to species and individuals.—*M. Comel.*

1421. **COHEN, MILTON B., E. E. ECKER, J. R. BREITBART, and J. A. RUDOLPH.** The rate of absorption of ragweed pollen material from the nose. *Jour. Immunol.* 18(6): 419-425. 1930.—A Prausnitz-Küstner reaction was performed with serum of a patient highly sensitive to ragweed, on 50 non-atopic subjects and 12 patients with asthma, hay fever, or vasomotor rhinitis, 9 of whom gave skin reactions by scratch tests. The patients were not naturally sensitive to ragweed. 24 hrs. later pollen was blown into both nostrils of non-atopic and atopic subjects and sites of injections observed for appearance of redness or wheal formation. The absorption time of the non-atopic subjects was 14-31 min., while that of the 9 sensitive subjects giving a skin reaction showed a marked delay, ranging from 47 min. to no reaction after 2 hrs. The other 3 with negative skin tests reacted like the non-atopics.—*Authors' summary.*

1422. **COLLIS, W. R. F., and A. G. WATKINS.** The immunology of scarlet fever: an unusual case. *Arch. Dis. Childhood* 5(30): 441-443. 1930.—The patient gave a negative Dick reaction when on the point of succumbing to an infection with scarlatinal streptococci, thus furnishing additional evidence that scarlatina is not a simple toxin-antitoxin phenomenon. The authors regard the Dick test merely as an indication of the presence of antitoxin in the patient's serum, and not as a guide to general immunity to scarlatinal streptococci.

1423. **CONIGLIO, GIUSEPPE.** Sull'ulcera gastrica anafilattica. [Anaphylactic gastric ulcer.] *Riv. Patol. Sperim.* 5(2/3): 178-186. 7 fig. 1930.—By experimental anaphylaxis in animals injected with fresh serum, a gastric ulcer may be induced; development is completed in 15 days, natural regression following.—*M. Comel.*

1424. **CORNBLEET, THEODORE, and R. E. MONTGOMERY.** Self-sterilization powers of the skin. *Arch. Dermatol. & Syphilol.* 23(5): 908-919. 1931.—Experiments partially described indicate that yeast cells are removed from the surface of the skin at an almost uniform rate that varies little from one area to another as long as the surface epithelium is normally dry and intact. The nail beds and areas immediately surrounding the nails are less efficient at sterilizing themselves than are other areas. Keratotic areas are no more efficient at removing

yeasts and staphylococci from their surfaces than are normal areas. Moist areas suffer a depression in sterilizing powers. Areas with denuded epithelium are not so efficient in removing yeasts and staphylococci as intact ones. Previous exposures of the intact skin to ultraviolet do not enhance its destructive powers against yeasts and staphylococci. Areas superficially infected with yeast, such as those of perléche, are barely capable of destroying yeasts. The unaffected areas symmetrical to those superficially infected are distinctly lower in sterilizing powers against yeasts than the normal areas, although higher than the affected ones. Persons susceptible to infections with yeast vary in yeast-sterilizing rates from time to time, and this variation appears to be somewhat periodic. Areas occupied by psoriatic lesions suffer from a loss of sterilizing powers as compared with uninvolved areas on the same individuals. Psoriatic lesions bared of scales free themselves of surface yeasts and staphylococci more quickly than do such lesions with scales.—*From authors' summary.*

1425. **DEBENEDETTI, E., e C. CURRADO. Delle spermoagglutinine. Aspetto morfologico della spermoagglutinazione. [Morphological aspects of spermoagglutination.]** *Boll. Soc. Ital. Biol. Sperim.* 5(3): 303-306. 1930.—The spermatozoa of guinea pigs, rabbits, sheep and dogs show a spontaneous agglutination which is apt to interfere with the spermoagglutination test. It was impossible to differentiate with certainty the morphological aspects of spontaneous and true agglutination. The pseudoagglutination was inhibited by adding to the suspension a solution of bile or taurocholate; it was then possible to demonstrate the specificity of serum spermoagglutinins.—*M. Comel.*

1426. **DELAFIELD, M. E. Changes in the blood sugar and blood phosphorus in rabbits following the injection of suspensions of Bact. aertrycke.** *Jour. Path. & Bact.* 34(2): 177-194. 1931.—Intravenous injections, into rabbits, of dead suspensions of *Bact. aertrycke* cause a hyperglycemia followed within 24 hrs. by a hypoglycemia. Inorganic blood P lessens in amount during hyperglycemia and increases during the hypoglycemic phase. Organic acid-soluble P also tends to increase during hyperglycemia. The same type of chemical response is found on injection of bacterial filtrate, alcohol-extracted organisms, acetone-extracted organisms or organisms treated by steaming or autoclaving. Diphtheria toxin produces no significant change in blood sugar or P within 24 hrs.—*M. E. Delafield.*

1430. **[DUKHOVNAĬA, A. ĬA.] ДУХОВНАЯ, А. Я. К вопросу о значении изоагглютинационных групп при туберкулезе. [Isoagglutinating groups in tuberculosis.]** [With French summary.] Вопросы Туберкулеза [*Voprosy Tuberkuleza*] 7(10): 1231-1233. 1929.—The author investigated 771 patients. Tuberculosis affected those of all 4 blood groups; however, the 1st and 4th showed a certain predisposition for the persistent forms of tubercule bacillus. The blood groups do not vary during the pulmonary process, nor during specific therapy. Exudative cases are encountered more frequently in the 1st and 4th groups, which also show a greater tendency towards hemoptysis.—*B. Van Rosen.*

1431. **EBERT, B. P., und L. H. PERETZ. Zur Frage der Serodiagnose der Lungenseuche. [Sero-diagnosis of contagious diseases of the lungs.]** *Zeitschr. Immunitätsforsch.* 58(1/2): 123-129. 1928.

1432. **EHRLICH, S. PAUL. A case report of severe snake-bite poisoning.** *Bull. Antivenin Inst. America* 2: (3): 65-66. 1928.—Severe symptoms originated by a *Crotalus atrox* bite and causing much discomfort were counteracted by application of 4 doses of antivenin, supplemented with various physical and chemical therapeutic means.—*A. do Amaral.*

1433. **FAIRBROTHER, R. W., and W. J. T. MORGAN. Further observations on the immunization of the horse with the poliomyelitis virus.** *British Jour. Exp. Path.* 11: 298-305. 1930.—2 horses were given courses of intravenous and intramuscular injections of filtrates containing poliomyelitis virus. Samples of serum collected at various times were tested for antiviral properties by neutralization test, using *Macacus rhesus* as test animal. The responses of the 2 horses differed considerably. In one, a serum with definite antiviral properties was produced; in the other no such properties were found in any of the serum samples tested.—*J. Bland.*

1434. **FAIRBROTHER, R. W., and W. G. SCOTT BROWN. The action of the serum of normal individuals on the virus of poliomyelitis.** *Lancet* 219(5591): 895-896. 1930.—As a result of experiments on *Macacus rhesus* monkeys and on man the author concludes that immunity to poliomyelitis virus, as indicated by the presence of antiviral bodies in the serum, is frequently present in normal people who have been in contact with definite cases of the disease without developing it. Results here recorded support Aycock's view that the observed immunity of adults to poliomyelitis is most probably due to "sub-clinical" infections.

1435. **FERRARO, F. Potere isoagglutinante del latte umano e reazione di Candido. [Iso-agglutinating power of human milk and Candido's reaction.]** *Riv. Clin. Pediatr.* 28(2): 123-133. 1930.—Candido claimed to have discovered that milk from a syphilitic woman would agglutinate erythrocytes from a normal, but not from a syphilitic, person; also that milk from a normal woman would not agglutinate erythrocytes from either normals or syphilitics. Using the hanging-drop method and centrifuged milk of 25 healthy and 16 syphilitic women, the author found that milk of a given woman agglutinates precisely the same erythrocytes that the same woman's serum would agglutinate; that is, iso-agglutination by milk follows the laws of blood groups. Candido's results are attributed to error in technique.

1436. **FILIPPIS, V. de, e C. SCAGLIONI. Sistema reticolo-istiocitario e produzione di anticorpi. [The reticulo-histocytic system and production of antibodies.]** *Atenco Parmense.* 2(5): 457-463. 1930.—Injection of Pb acetate into rabbits previously or subsequently inoculated with typhoid produced a serum capable, even in dilution of 1: 3200 (as against 1: 400 for controls), of strongly agglutinating typhoid bacilli. The opsonic index of the serum of rabbits treated with Pb acetate was 1.2, taking the opsonic index of untreated controls as 1.

1437. **FITZGERALD, J. G., and D. T. FRASER. Human immunity to diphtheria.** *Trans. Roy. Soc. Canada, Sect. 5, Biol. Sci.* 24(1): 111-115. 1930.—The diphtheria antitoxin content of the blood of mothers and their newborn infants was studied. Generally, the content of the newborn was less than that of the mother. Studies on the natural diphtheria antitoxin content of the blood of various adults showed constant values over a year or more.

1438. **FRANTA, KARL. Zur Auswahl der Impftiere bei der Gewinnung von Hammelblutlysinen von Kaninchen. [Selection of animals for production of rabbit anti-sheep amboceptor.]** *Zeitschr. Immunitätsforsch. u. Exp. Therap.* 66(3/4): 335-349. 1930.—Since not all rabbits are equally good amboceptor producers, an attempt was made to increase the number of good reactors by

selection of animals. The anlage of immune hemolysin production is inherited and selective breeding can produce a good line. The normal hemolysin titer of inactivated serum from a given rabbit is no indication of a high immune hemolysin in that animal.—*N. W. Larkum.*

1439. **FUNK, ELMER H., and F. M. HUNTOON.** Biochemical studies of bacterial derivatives. XI. Skin reactions in man with human tubercle bacillus protein MA-100. Preliminary report. *Jour. Immunol.* 19(2): 237-253. 1930.—A comparison was made of the skin reactions produced by a tuberculin "O.T." and by a human tubercle bacillus protein MA-100. It was found that: A skin reaction to protein MA-100 occurs in the majority of adults tested, and in slightly greater incidence than that produced by tuberculin "O.T." The type of reaction is that seen with tuberculin "O.T." but it is apt to be less intense and more transitory. A dosage of 0.0005 mgm. was adopted. As judged by reactions in tuberculous individuals and tuberculous animals, the protein is as specific as tuberculin "O.T." Disagreeable or dangerous reactions are less apt to occur with the protein. Incidence of reactions found were: (a) In known tuberculous cases 94.1% with protein; 90.6% with tuberculin "O.T." (b) In clinically tuberculous cases with negative sputa, protein gave 92.9%; tuberculin "O.T." 91.2%. (c) In clinically non-tuberculous cases, protein gave 81%; tuberculin "O.T." 71.5%. On the basis of the work to date, it may be said that as a diagnostic agent, protein MA-100 is as good as, and possibly better than, tuberculin "O.T.," especially in view of the fact that it is a pure substance as compared with the very complex composition of tuberculin "O.T."—*Authors' conclusions.*

1440. **FURUHATA, TANEMOTO.** The distribution of blood groups of the Japanese. III. *Japan Med. World.* 8(11): 287-291. 1928—The Japanese have a unique blood group distribution; it is like that of Hungarians of Mongol origin, natives from Hunan province and some tribes of Formosa. Analysis of the author's statistics shows that mixture with Koreans has influenced their blood group distribution. He suggests that W. Kruse's racial point method may be most convenient for showing blood group distribution. Races differing much in racial points may have the same ancestors; and, however near the race points of some races are, they may by no means be of the same origin.—*Cora M. Downs.*

1441. **FUTAGI, YASUO.** Improvement of the prophylactic immunization against scarlet fever by means of anatoxin after Ramon's method. *Jour. Immunol.* 19(5): 451-456. 1930.—As a result of immunization experiments on children in the Dairen primary schools, the author recommends use of anatoxin for prevention of scarlatina. The material may be prepared by treating toxin with 0.4% formalin at 40° C. for 60 days or at 45° for 30 days. Such anatoxins produce comparatively slight reactions and retain sufficient antigenic power.—*L. A. Barnes.*

1442. **GARDNER, RAYMOND E., and ROSCOE R. HYDE.** Immunity to transplantable rat tumors. *Amer. Jour. Hyg.* 13(3): 649-684. 1931.—Preliminary treatment of a susceptible strain of rats with fresh sterile whole blood from the normal chicken proved effective in producing resistance to a transplantable spindle cell sarcoma. Complete inhibition of grafts was produced in 86% of the treated animals, as compared with 19% negative in controls. In grafts that developed, marked retardation was observed. Similar treatment of a susceptible strain of rats proved effective against a medullary carcinoma of high proliferative vigor, as shown by failure of grafts to develop in 39% of treated animals, while controls all gave positive takes. Considerable restraint of growth in positive cases was produced by treatment. In a susceptible rat, treatment with non-hemolyzed, heat-devitalized whole blood from the normal chicken proved effective, but to a much less extent than fresh normal chicken blood, in producing resistance to sarcoma in 77% of animals treated, as compared with 50% negative in controls. Treatment of a susceptible strain of rats with non-hemolyzed, heat-devitalized, whole chicken blood produced slight immunity to carcinoma. Complete inhibition of grafts resulted in only 6.6% of treated animals, with slight retardation in those developing tumors, while controls developed in 100% of cases. A susceptible strain of rats treated with whole, dried blood from the normal chicken, collected and desiccated under sterile conditions, was not refractory to implantation of sarcoma and carcinoma. Feeding of fresh, whole blood daily to susceptible strains produced no resistance to implantations of sarcoma and carcinoma. Preliminary treatment of a susceptible strain with blood-free chick embryo skin was somewhat effective in producing resistance to sarcoma, as shown by 63% failing to develop in the experimental group as compared to 49% in controls. However, no immunity to carcinoma was produced by the treatment. A susceptible strain of rats treated with vaccine virus proved resistant to sarcoma. The immunity prevented the taking of the grafts in 75% of the treated animals, as compared to 14% negative in controls. Growth of those that developed was restrained. In susceptible strains negative results were obtained with vaccine virus against carcinoma. Vaccine virus could not be recovered either from sarcoma or carcinoma (after direct injection) after 9, 11, 12, 13 and 14 days by the usual animal inoculations made before and after subjecting the material to cataphoresis. Susceptible rats, proved refractory by unsuccessful inoculation of sarcoma, were resistant in 46% of cases on subsequent implantation of carcinoma, controls always developing in 100% of cases. No evidence of local immunity could be determined by intracerebral implantation of carcinoma, since it failed to grow in the brain of rats already proved immune by subcutaneous implantation. No increase in susceptibility of rats naturally refractory to subcutaneous implantations of sarcoma could be noted after brain implantation. Treatment of a susceptible strain of rats with rapidly dried carcinomatous tissue failed to produce resistance to subsequent implantation of the same tumor.—*Authors' summary.*

1443. **GELLI, GIUSEPPE, e GIANCARLO TAROZZI.** Il comportamento della isoagglutinazione umana nella malattia da siero. [Isoagglutination in man during serum disease.] *Biochim. e Terapia Sperim.* 17(10): 419-427. 1930.—In children with diphtheria treated by therapeutic serum and suffering from serum disease, the isoagglutinin content of the blood diminished during anaphylaxis, but came back to normal values afterwards.—*M. Comel.*

1444. **GITHENS, THOMAS S., and LEWIS W. BUTZ.** Venoms of North American snakes and their relationship. *Bull. Antivenin Inst. America* 2(4): 100-104. 1929.—Experiments were made on the venoms of 6 nearctic rattlesnakes (*Crotalus adamanteus, atrox, exsul, horridus, mitchellii* and *oreganus*), the 2 moccasins (*Ankistrodon mokasen* and *piscivorus*), the neotropical rattler (*C. terrificus*) and the Fer de lance (*Bothrops atrox*), with the following results: The venoms of the 6 North American rattlesnakes studied contain identical or almost identical toxic principles. The toxic principles of the copperhead and moccasin are almost or quite identical, but differ to some extent from those of the rattlesnakes. The venoms of *Crotalus terrificus* and of *Bothrops atrox* contain principles differing entirely from those of the nearctic rattlesnakes as regards antigenic properties. Rattlesnake venoms contain, in addition to their acutely toxic principles, other components which bind antibodies, but are not acutely toxic to pigeons.—*A. do Amaral.*

1445. **GIUSEPPE, ARMUZZI.** Fenomeni allergici nell' infezione da streptobacillo di Ducrey. [Allergic phenomena in infections by Ducrey's streptobacillus.] *Boll. Ist. Sieroterap. Milanese* 7(8/9): 511-517. 1928.—The diagnostic intradermal reaction with Nicolle streptobacillus vaccine (Dmelcos) or with the pus from a venereal bubo is definitely specific, both during the course of the venereal ulcer or its complications and in the chronic progressive type of long duration (in one case 40 years);

hence, the diagnostic value of the reaction and its practical application. At the same time the importance of the skin is seen as an essential factor in the allergic reaction as tried out by the author in various portions of the skin and mucous membranes. Experiments conducted to locate a humoral immunizing factor in attempts to transmit a passive hypersensitivity from man to man and from man to animals were negative, as were also the results in vitro.—*Author's summary (transl. by P. Hillkowitz).*

1446. **GLENNY, A. T., and M. LLEWELLYN-JONES. The importance of the in vitro in vivo ratio of diphtheria antitoxin.** *Jour. Path. & Bact.* 34(1): 110-111. 1930.

1447. **GLENNY, A. T., and M. BARR. The precipitation of diphtheria toxoid by potash alum.** *Jour. Path. & Bact.* 34(2): 131-138. 1931.—Precipitates produced by addition of different quantities of alum to diphtheria toxoid were examined with respect to specific antigen content and relative purity, expressed in terms of Lf units per mgm. of nitrogen. The amount of alum required to effect maximum precipitation of antigen is not the same for toxoids produced from different types of media. The amount of specific material precipitated varies with quantity of alum in relation to volume of a given toxoid, irrespective of dilution or method of addition.—*A. T. Glenny.*

1448. **GLENNY, A. T., and M. LLEWELLYN-JONES. The intracutaneous method of testing diphtheria toxin and antitoxin.** *Jour. Path. & Bact.* 34(2): 143-156. 1931. —A detailed description of the method is given. Evidence shows the advantage of intracutaneous over subcutaneous testing in regard to economy of animals, accuracy and rapidity. By this method it is possible to determine the presence of as little as 1/50,000 unit of antitoxin in 0.1 cc. of serum.—*A. T. Glenny.*

1449. **GLENNY, A. T., M. LLEWELLYN-JONES, and J. H. MASON. The intracutaneous method of testing the toxins and antitoxins of the "gas gangrene" organisms.** *Jour. Path. & Bact.* 34(2): 201-211. 1931.—Descriptions are given of the reactions produced by intracutaneous injection into guinea pigs of the toxins of *B. welchii*, vibrion septique, *B. oedematiens*, "lamb dysentery bacillus" and *B. histolyticus*. Results of intracutaneous titrations of the various antitoxins are compared with results obtained by other methods of test, and show that all 5 antitoxins can be titrated with reasonable accuracy.—*A. T. Glenny.*

1450. **GLENNY, A. T., G. BUTTLE, and M. STEVENS. Rate of disappearance of diphtheria toxoid into rabbits and guinea-pigs.** *Jour. Path. & Bact.* 34(2): 267-275. 1931.—The rate of elimination of toxoid injected into animals was studied by 3 methods: (1) Blocking of immunity in guinea pigs injected with toxoid by injecting antitoxin at various intervals afterwards; (2) measuring the toxoid in the blood of rabbits after an injection; (3) injecting a neutralizing dose of antitoxin after the toxoid, and estimating the excess antitoxin in the blood. All 3 methods show that toxoid is eliminated or destroyed very rapidly, some 10-30% only remaining at the end of 24 hrs. Toxoid precipitated by alum is retained, in part, near the site of injection and therefore acts as a more prolonged stimulus than plain toxoid, hence its increased antigenic efficiency. Other precipitating agents, e.g., $Ce(NO_3)_3$, $ZnSO_4$ and $CaCl_2$, act in a similar manner.—*A. T. Glenny.*

1451. **GOLDSWORTHY, N. E., and H. FLOREY. Some properties of mucus, with special reference to its antibacterial functions.** *British Jour. Exp. Path.* 11(3): 192-208. 1930.—The inhibitory, lytic and bactericidal powers of alimentary mucus, tears and nasal secretions were studied on 4 organisms, 2 especially sensitive to lysozyme, 1 moderately sensitive, and 1 completely resistant. The bulk of the experiments were performed on cats. Cat's tears are entirely devoid of lytic properties; saliva, on the contrary, contains a considerable amount of lysozyme, but it cannot be detected in mucus from the stomach or colon, though a small amount, as compared with other animals, can be demonstrated in saline extracts of dried mucosa. Dog's tears, saliva and nasal mucus have marked lytic properties, and detectable amounts of lysozyme are present in mucous membranes and washings,—much more in the colon than in stomach mucosa. Rabbits have marked lytic powers in both washings and extracts of mucosa; the colon was much more active than the stomach, and the small intestine fell midway between; the saliva was much less active than colon extract. Guinea pigs reverse the relationship; the stomach is more potent than the intestine. Goats showed complete absence of lysozyme in saliva at a dilution of 1/10. Colon washings showed a trace of lysis; tears were quite active.—*J. Bland.*

1452. **GOODNER, KENNETH. Incidence of blood groups among the Maya Indians of Yucatan.** *Jour. Immunol.* 18(6): 433-435. 1930.—223 pure Mayas and 202 people of mixed Maya and Spanish blood were grouped. A high percentage incidence of Group O was found, in the case of the Mayas amounting to 97.7%. This points to the racial purity and antiquity of the Maya stock.—*Author's summary.*

1453. **GOODNER, KENNETH. Experiments on the concentration of antipneumococcic and antimeningococcic horse sera.** *Jour. Immunol.* 19(5): 473-484. 1930.—Description of some of the properties of the "antibody euglobulin" of these sera, together with a simple procedure for its concentration.—*K. Goodner.*

1454. **GORDON, J. The relationship between complement and opsonin. Experiments with Congo red.** *Jour. Immunol.* 19(3): 303-305. 1930.—Congo red and similar dyes prevent the bactericidal and hemolytic (complement) activities of normal serum. A serum whose complement has been inactivated by certain concentrations of congo red is still able to exert its opsonic activity.—*Author's summary.*

1455. **GORI, PIO. Emolisi e ambocettori emolitici (di un loro particolare rapporto in alcune condizioni di immunizzazione). [Hemolysins and hemolytic amboceptors (particularly with reference to some phases of immunization).]** *Lo Sperimentale* 84(4): 237-256. 1930.—The serum of a rabbit which can hemolyze pigeon erythrocytes, loses this power after the rabbit has been immunized against pigeon blood. Serum of a rabbit with no hemolytic power for pigeon erythrocytes manifests such hemolytic power during the first stage of immunization, but loses it later during immunization when the antibody content becomes high. These observations parallel similar phenomena showing loss of the bactericidal power of serum following vaccinal treatment with *B. typhosus.*—*M. L. Menten.*

1456. **GRABOW, C., und F. PLAUT. Experimentelle Untersuchungen zur Frage der Antikörperbildung im Liquorraum. [Experimental investigations of antibody formation in the cerebrospinal fluid.]** *Zeitschr. Immunitätsforsch. u. Exp. Therap.* 54(3/4): 335-354. 1928.

1457. **GREENFIELD, GREGOR. Experimentelle Untersuchungen über gruppenspezifische Antigene und Antikörper.** *Zeitschr. Immunitätsforsch. u. Exp. Therap.* 56(1/2): 107-129. 1928.—Several normal human sera were found which contained group-specific complement-deviating antibodies for human erythrocytes, reactions also given with lipoids extracted from these erythrocytes. The same group-specific isoantibodies are demonstrable in normal human saliva. Group-specific antibodies for human erythrocytes and for human myocardial emulsions are demonstrable in normal beef serum, and can be produced experimentally in rabbits.—*Author's summary (transl. by W. H. Manwaring).*

1458. **GRINNELL, FRANCIS B. A study of the comparative value of rough and smooth strains of B. typhosus in the preparation of typhoid vaccines.** *Jour. Immunol.* 19(5): 457-464. 1930.—The customary course of prophylaxis with a vaccine made from a rough (R) strain of *B. typhosus* "Rawlins" produces little or no increase in bactericidal power of blood. A similar course of treatment with a vaccine made from a smooth (S), virulent strain of *B. typhosus* causes a considerable increase in bactericidal antibodies. In so far as the bactericidal

test is an index of individual resistance, typhoid vaccine in which R strains are employed are valueless for prophylaxis. Vaccination with R strains leads to production of agglutinins for virulent strains, with no increase in bactericidal power of blood. Agglutination is therefore not an adequate test of the resistance of the individual.—*Author's conclusions.*

1459. GROB, MAX. Über die Beziehungen der Isoagglutination zum Icterus neonatorum. *Zeitschr. Kinderheilk.* 50(6): 726-741. 1931.—Blood group relations were obtained on 100 newborn with jaundice and on their mothers, to determine in how far phenomena of isoagglutination entered into the genesis of icterus neonatorum (I.N.). The % of the blood groups between mothers and children and between boys and girls was about the same. A certain increase in group I and decrease in IV were observed and related to jaundice, but differences lay within the limit of error. Homospecific pregnancies were found in 52% and heterospecific in 48%. No predominance of heterospecificity could be found in I.N. Agglutinophil reactions were found in only ⅓ (32%) of the cases. These agglutinations could not be regarded as the sole or principal cause of I.N., but a direct proportionality between reactions and severity of disease indicated their importance. Milk of 100 mothers of jaundiced children was examined for agglutinins, and blood cells of children for agglutination with mother's milk, to determine in how far isoagglutination of infantile blood cells by resorbed milk concerned the genesis of I.N. In 84% the milk contained agglutinin; the other 16% were principally of group II. In 67% the same agglutinins appeared in milk and in maternal serum. In 5 cases in group IV, not all the expected agglutinins (α and β) were found; usually β was absent. In 12%, the so-called X-group of milk contained agglutinins against group IV and against homospecific blood cells. Infantile blood cells were agglutinated by mother's milk in 33% of the cases; 22% of these showed agglutinophil blood group correlations, so that in only 11% did the properties of the milk give a + agglutination in contrast to serum. Milk agglutination appeared to have no influence on degree of jaundice. With reference to possible milk agglutination in blood of jaundiced infants, signs of isoagglutination could not be found in ½ the cases, so that it plays no primary rôle.—*From author's summary (transl.).*

1460. GROS, ERNST. Die serologische Elternschaftsdiagnose nach Zangemeister. *Zeitschr. Geburtsh. u. Gynäkol.* 99(3): 387-394. 1931.—In 60 unmixed sera, only 18 showed the same clearness after warming; in 34, there was a decrease in clearness of about 11%; in 8, the reaction was irregular. Refrigeration did not appear to affect it; when bacterial impurities were present, clearness increased 50-100%. All sera were obtained on a fasting stomach. In 70 sera from mother-child and mother-unrelated child (10 cc. mother : 1 cc. child), mother-child showed an average decrease of 17% (5-35%) and mother-unrelated child, 12% (0-25%); in 10 instances, clearness was greater in mother-unrelated child than in mother-child. Of the 60 curves, positive in Zangemeister's sense, only 19 varied more than 10%; 18 lay between 5 and 10%; 23, below 5%. No practical use could be made of the reaction. In 15 instances of father-child and father-unrelated child (10 cc. father; 1 cc. child), decrease in clearness averaged 19% (10-25%) and 9% (2-18%), respectively. In 15 instances the serum of a parturient woman was tested with that of the child's father and that of another man. The decrease in clearness was 25% (15-30%) and 14% (0-19%), respectively. The father-child and father-mother tests might prove useful. In both these, greatest decrease in clearness occurred during the 1st hr., probably owing to "individually specific" antibodies in the mother's (and child's) blood caused by immunization from the sperm protein after conception; this would also explain the negative outcome of mother-child tests. When 10 cc. child's and 1 cc. father's blood were used, decrease in clearness averaged 15% (6-23%) father-child and varied between 0 and 12% with child and another man. This may prove a refinement of Zangemeister's method.

1461. GRÜNWALD, BERNHARD. Die Beeinflussung der Isoagglutininmengen durch Schwangerschaft, durch Entzündung und durch Röntgenbestrahlung. *Zeitschr. Rassenphysiol.* 3(2): 71-93. 1930.—The author reports that the isoagglutinin titer in cases of group O, but not in group A, is considerably increased after abortions, and during puerperium isoagglutinins of low titer were demonstrated in blood from the umbilical cord. In all cases of homospecific pregnancy an increased titer was observed during the period of recovery from acute or chronic inflammatory genetical conditions. Roentgen radiation had no effect on the isoagglutinin titer.—*P. Levine.*

1462. GRZYBOWSKI, MÁRJAN. Die Allergie der Haut bei der Syphilis. *Acta Dermato-Venereol.* 11(1): 55-69. 1930.—In 110 cases all tests employed led to the following conclusions: The manner in which the skin reacts to a foreign albumin can hardly be used as final basis for division into anergic and allergic lues; everything points to the existence of an allergy to foreign albumin in lues; cutireaction tests with albumin preparations are subject to the laws of anaphylaxis; for that reason, prognostic conclusions on the further course of lues cannot be drawn from such tests; Busson's luetin frequently gives an unspecific reaction. The author was unable to discover that lues of the 3rd degree should give stronger positive reactions. It is possible that there exists an anergy against tuberculin in the florid stages of lues.

1463. GUNDEL, M. Rassenbiologische Untersuchungen an der Schleswig-Holsteinischen Bevölkerung. Blutgruppen und Krankheiten. *Zeitschr. Immunitätsforsch. u. Exp. Therap.* 56(1/2): 60-76. 1928.—The author finds that in dementia praecox, psychoses and in late lues, group B is more frequent than in the general population; while in epileptic, senile, and arteriosclerotic dementia, there are normal or even slightly lower values of B. While no satisfactory explanation is as yet available, the author cites the fact that it is more difficult to change the Wassermann reaction from positive to negative in luetics of groups B and AB than in those of groups O and A.—*Author's summary (transl. by P. Levine).*

1464. HACH, IW., und V. MELNYK. Studien über Gewebeinfektion und Gewebeimmunität. [Studies on tissue infection and tissue immunity.] *Zeitschr. Immunitätsforsch. u. Exp. Therap.* 54(3/4): 269-284. 1 fig. 1928.

1465. HALLAUER, C. Zur Isolierung der gruppenspezifischen Antigene menschlicher Erythrozyten. [Isolation of specific antigen groups of human erythrocytes.] *Schweizerische Med. Wochenschr.* 59(6): 121-122. 1929.

1466. HAMBURGER, CHR. Ueber den Isoagglutiningehalt des Retroplazentarblutes. *Zeitschr. Rassenphysiol.* 3(2): 66-70. 1930.—The author confirms the observation of Hirszfeld and Zborowsky, and of Lidberg, that the agglutinins in the retroplacental blood in cases of heterospecific pregnancy are considerably diminished. He shows that the diminution is not merely a dilution effect; but believes it to be due to the presence in the liquor amnii of group-specific inhibiting substances derived from the offspring.—*P. Levine.*

1467. HAUSMANN, W., und A. FISCHER. Über Lichtwirkung auf Tuberkulin. *Strahlentherapie* 40(4): 750-756. 2 fig. 1931.—Old tuberculin in dilutions of 1 : 1000 and 1 : 500, after irradiation in 0.4 cm. layer with a quartz mercury lamp at 20 cm., was inactive in intracutaneous test on tuberculous patients; stronger concentrations were partially inactivated. Albumin-free tuberculin similarly treated showed some inactivation at 1 : 10. Inactivation continued after interposition of a glass plate which allowed waves to pass only to $\lambda = 307\mu\mu$ and weakened those from $\lambda = 322\mu\mu$. While inactive in skin tests, the irradiated old tuberculin often called forth focal and general reactions, i.e., when irradiated it lost its toxicity for the skin. Guinea pigs injected with ir-

radiated old tuberculin, reduced in water bath to 1:5 and 1:10, showed neither cutaneous reaction nor died.

1468. HAZEN, ELIZABETH LEE. The relation of the bacterial precipitin reaction to the Ramon flocculation phenomenon. *Jour. Immunol.* 19(4): 393-403. 1930.—Flocculation in mixtures of filtrate of *Corynebacterium diphtheriae* with antitoxin is not limited by the agglutination types serving for toxin production. Precipitation in mixtures of toxic filtrate with agglutinating serum is restricted to agglutination types. Removal of bacterial antibody from antitoxic serum by absorption of serum with bacterial extracts does not prevent subsequent flocculation of serum with toxic filtrate, whereas agglutinating serum treated in the same manner no longer precipitates with toxic filtrate. The Ramon reaction is probably due to interaction between toxin and antitoxin rather than between bacterial precipitinogen and precipitin.—*E. L. Hazen.*

1469. HEIMANN, F., und J. STEINFELD. Über das Verhalten der Hirnlipoide und ihrer Antisera. [The behavior of the brain lipoids and their antisera.] *Zeitschr. Immunitätsforsch.* 58(1/2): 181-192. 1928.

1470. HEIMBECK, J. Sur la vaccination préventive de la tuberculose par injection sous-cutanée de BCG chez les élèves infirmières de l'hôpital Ulleval, à Oslo (Norvège). *Presse Méd.* 37(86): 1391. 1929.—Of 34 unvaccinated student nurses, 14 (41.2%) contracted more or less serious forms of tuberculosis. Of 136 vaccinated, 3 (2.2%) presented slight signs of pleurisy. Vaccination caused no undesirable results.

1471. HEKTOEN, LUDVIG, and WILLIAM H. WELKER. Is ferratin precipitinogenic? *Proc. Soc. Exp. Biol. & Med.* 28(3): 293-294. 1930.—Ferratin, by many regarded as probably a nucleoprotein, was prepared with care to eliminate blood proteins. It possessed at most only a comparatively slight precipitinogenic power, the resulting precipitins in some cases reacting also with other ferratins than the one used as antigen. The question whether ferratin is a species-specific antigen has not been definitely settled.

1472. HELLMAN, T., und G. WHITE. Das Verhalten des lymphatischen Gewebes während eines Immunisierungsprozesses. *Virchow's Arch. Path. u. Physiol.* 278 (2): 221-257. 1930.—Investigations on 23 rabbits (in 4 groups, according to age and time of experiment) to determine the rôle of lymphatic tissue during active immunization with *Bacillus paratyphosus B*, had the following results: The spleen was most affected. It grew larger, due to heavy proliferation of secondary nodules and of white and red pulp. The remaining lymphatic tissue was much less affected. The pharyngeal tonsils showed a tendency to enlarge. In the lymph nodes and especially in the lymphatic tissue of the intestine, the only thing noticeable was the absence of occasional areas of involution. One may conclude, especially from the findings in the spleen, that the lymphatic tissues were in a very hyperactive state. Above all, the reticular portion was in an active condition as shown by extraordinary development of the secondary nodules, which were increased both in size and number. The task of the reticulo-endothelial system during immunization appears to be partly to act defensively, and partly to produce antibodies. As Hellman has long claimed, these results might be accomplished in large part by the secondary nodules.—*Authors' summary (transl. by A. Hoyt).*

1473. HESCH, MICHAEL. Deutsches Schrifttum über die Blutballung. [German literature on blood agglutination.] *Zeitschr. Rassenphysiol.* 2(4): 184-186. 1930.

1474. HERIVAUX, A., et R. RAHOERSON. Les groupes sanguins chez les Malgaches de l'Emyrne. *Bull. Soc. Path. Exotique.* 24(3): 247-250. 1931.—The authors classified 273 bloods of Madagascans (their AB, A, B and O groups correspond, respectively, to the I, II, III and IV of Moss). Of 61 identifications from the "andriana" or nobles, 18% belonged to group AB, 31.66% to group A, 16.66% to group B, and 35% to group O; the biochemical index was 1.42. Of 112 identifications from the "hova" or common people, 23.21% belonged to group AB, 26.78% to group A, 25.89% to group B, and 24.10% to group O; the biochemical index was 1.01. Of 100 identifications from the "mainty" or blacks, 5% belonged to group AB, 30% to group A, 23% to group B, and 42% to group O; the biochemical index was 1.25. The comparative frequency of the AB group among both the "andriana" and the "hova" (as opposed to the "mainty") is doubtless explained by their common origin.

1475. HERZ, OSCAR. Das weisse Blutbild bei der Pockenschutzimpfung. (Entgegnung auf die Arbeit von Eckstein und Brinitzer, Zschr. f. Kdhk. 49, 3.) *Zeitschr. Kinderheilk.* 50(2): 224-230. 1930.—Comparison of the hemograms of a number of infants showed that the leukocytes behave typically in the first vaccination, the shift to the left being proportional to mildness of clinical source. After a short rise, the leukocytes tend to fall. The differential hemogram shows 3 phases—a brief primary rise in leukocytes, a drop in lymphocytes, and then a continuously rising lymphocytosis. The granulocytes behave opposite to the lymphocytes; the monocytes rise. Considered absolutely, the lymphocytic recovery phase appears very much later than when considered relatively. No increase in plasma cells could be found. Since this study was comparative, the author believes the alterations in the hemogram to be a specific result of vaccination.—*From author's summary (transl.).*

1476. HIGUCHI, S. Über die für die menschlichen Blutgruppen spezifischen Immunkörper und deren Antigene. *Fukuoka Acta Med.* 21(10): Japanese, 2019-2055; German summary, 98-99. 1928.—The author obtained group-specific immune agglutinins for human blood by injecting rabbits with blood cells or stroma of groups A and B. Stromas derived from old coagula, washed 10 times, very seldom possess the property of inducing group-specific or species-specific agglutinins. However, addition of serum of group AB to the stroma prepared as mentioned, renders the mixture antigenic, but only species-specific antibodies are produced. The author also reports experiments made on the relationship of human A and the Forssman antigen.—*P. Levine.*

1477. HILL, L., M. GREENWOOD, and W. W. C. TOPLEY. On the effect of ultra-violet irradiation upon the resistance of mice exposed to Pasteurella infection. *British Jour. Exp. Path.* 11(3): 182-190. 1930.—An experiment was done on a large scale, involving use of more than 1000 mice, to test whether, in animals exposed under approximately normal conditions, irradiation conferred any immunity from fatal infection. To a herd of more than 100 mice infected with *Pasteurella*, 3 normal and 3 irradiated mice were added daily from May 15 to December 31, 1929, when the experiment was terminated. The irradiated mice were exposed for 48 hrs., at a distance of 4 ft., to the rays from a frosted vitreosil tubular mercury vapour lamp, screened by a sheet of glass permeable to ultraviolet up to 2850 AU, but not to shorter rays; along either side was a row of incandescent lamps sufficient to balance the blue light and to produce colors equivalent to those of sunlight. A fan was kept running to keep the cages cool and the mice were not shaved. From the vital statistics of the experiment, it is clear that irradiation conferred no advantage on the treated animals in respect of the hazards to which they were exposed.—*J. Bland.*

1478. HOEN, E., und L. TSCHERTKOW. Ueber bazilläre Immunität bei Diphtherie. *Zentralbl. Bakt. I. Abt. Orig.* 120(5/6): 320-323. 1931.—Of 15 guinea pigs, each subcutaneously inoculated 5 times with immunizing doses of killed diphtheria bacilli, 3 (with 2 controls), 20 days after the last inoculation, were subcutaneously injected with twice the lethal dose of living diphtheria bacillus freed from toxin; 23 days after the last inoculation 5 vaccinated guinea pigs (with 2 controls) received each a lethal dose (300 million) of living detoxicated bacilli; and 3 vaccinated guinea pigs (with 1 control) received successive sublethal doses (5-100 million). In no case did vaccinated guinea pigs manifest greater immunity than controls.

1479. HOEN, E., L. TSCHERTKOW, und W. ZIPP. Antieiweiss- und antitoxische Präzipitine. [Anti-albumin and antitoxic precipitins.] *Zeitschr. Immunitätsforsch.* 58(1/2): 143-158. 1928.

1480. HOLMAN, W. L. Fatigue and infection. *Ann. Internal Med.* 3(3): 259-266. 1929.—A general consideration of the question of cellular fatigue and the multiplicity of causes for it, is here correlated with conditions favoring bacterial infections. Fatigue can be induced by underwork as well as by overwork, by faulty nutrition and by many other factors, and is the basis of much of what is referred to as lowered resistance. The failure in functional reserves to meet such emergencies as infections is the important suggestion in this paper, and that fatigue is the warning of such failure and rest the cure.—*W. L. Holman.*

1481. HOLSCHER, F. Untersuchungen über den Blutgruppentiter bei fortgeschrittener Tuberkulose. *Zeitschr. Immunitätsforsch. u. Exp. Therap.* 66(3/4): 193-203. 1930.—Blood groupings with normal serum groups O, A and B showed that the largest proportion had a titer of 1/128. Sera of the same groups from patients with tuberculosis gave a titer of 1/32 for the same percentage of sera. The anti-A titers were higher than the anti-B. Although no evidence is yet available it may be found that the titer of isoagglutinating sera has prognostic value in tuberculosis.—*N. W. Larkum.*

1482. HORRALL, O. H., and G. EARLE WAKERLIN. Experimental syphilis in rabbits. II. A comparative study of the Kahn and Wassermann reactions. *Arch. Dermatol. & Syphilol.* 23(5): 856-862. 1931.—Paired Kahn and Wassermann tests (317) were performed on 44 rabbits over a period of 10 mos.; in 14 instances comparison of results of the 2 reactions was impossible because of anticomplementary action of the sera in the Wassermann tests. Results indicate that as the Wassermann shows a high % of false positiveness and a definite proportion of anticomplementary reactions, the Kahn test is decidedly superior as a diagnostic agent in experimental syphilis in rabbits.

1483. HUNTEMÜLLER, O. Die Wirkung der Lichtstrahlen auf die natürlichen Abwehrkräfte (Alexine) im Blutserum. 1. U.V. Strahlenwirkung. *Strahlentherapie* 35(3): 489-500. 1930.—The studies were made with the micromethod devised by the author for exact measurement of free complement. 2 quartz Hg lamps (Hanau) were placed 1 m. from the subjects and determinations made before and at definite intervals after radiation. The amount of complement shows a more or less graded increase following radiation. The stimulus acts directly on the skin capillaries and their endothelium or its sympathetic nerves and exerts a secondary, indirect action through destruction products of epidermis cells (erythema forming) on the formation of complement in the organism. It is concluded that the action of ultraviolet on the body is in no small measure dependent on the increase and rapid regenerative ability of natural complement, although the action on the nervous system must also be considered.—*O. Huntemüller (transl. by H. S. Mayerson).*

1484. [ЯSKOL'KO, S. M., and S. S. PANKOVA.] ЯСКОЛЬКО, С. М., и С. С. ПАНКОВА. Серодиагностика сифилиса по методу Sormani и инструкция. **[Serodiagnosis of syphilis by Sormani's method.]** [With German summary.] Венерология и Дерматология [*Venerol. i Dermatol.*] 1929(11): 59-63. 1929.—The authors tried to determine whether the capacity of antigen to bind complement would increase with increase in dose; whether there is a definite relation between intensity of reaction and decreasing amounts of antigen, and whether the method is to be preferred to the standard Wassermann. Having performed 924 experiments with this method they conclude: Though there are only negligible differences between the methods, the Sormani is not preferable, for every serum must be treated in 6 test-tubes and with only 1 antigen, whereas according to the standard Wassermann, serum is tested in 4 tubes only, and with 3 different antigens. Capacity of antigen to bind complement does not increase so often, nor in all cases, with increase of dose. There is no strict correlation between intensity of reaction and quantity of the extract with which it is performed.—*B. Van Rosen.*

1485. [IZABOLINSKIĬ, M. P., and V. I. GITOVICH.] ИЗАБОЛИНСКИЙ, М. П., и В. И. ГИТОВИЧ. Экспериментальные данные по изучению свойств дифтерийных анатоксинов. **[Data obtained from experimental study of the properties of diphtheria anatoxins.]** [German summary.] Микробиологический Журнал, Бактериологический Институт им. Пастера (*Jour. Microbiol., Inst. Bact. Pasteur*) 10(2/3): 206-210. 1930.—Immunization with anatoxin and total-anatoxin was tried on 125 guinea pigs, both fresh and 1-2-yr.-old anatoxins being used. Guinea pigs immunized with anatoxin displayed a high degree of insusceptibility towards either diphtherial toxins or pure cultures of diphtherial bacilli. The latter sometimes provoked cutaneous irritations, which, however, were easily cured by application of specific antivirus. For immunization, anatoxin-total, recommended by Ramon, proved in no way superior to toxoid. On the contrary, it was less acceptable in practice, since it caused many unpleasant local skin irritations. Single injection of 5 cc. of anatoxin often sufficed to produce a high degree of immunity against both toxoids and pure cultures. Guinea pigs immunized with anatoxin preserved this immunity for 2½ yrs. and survived 300 lethal doses or 5 cc. of virulent culture. Moreover, this immunity was transmitted to the 2nd generation. Some of the young guinea pigs born of immunized mothers withstood as many as 50 lethal doses of toxin. The authors admit that this hereditary immunity is still subject to further research.

1486. JADASSOHN, JOSEF. The importance of immune biologic processes in the morphology of skin lesions. *Arch. Dermatol. & Syphilol.* 21(3): 355-368. 1930.

1487. JADASSOHN, WERNER, und JUI-WU MU. Über die Immunbiologie der Haut beim Rotlauf (Erysipeloid). *Arch. Dermatol. u. Syph.* 162(1): 210-216. 6 col. fig. 1930.—Intracutaneous infection of rabbits with erysipeloid bacilli leads to reddening, central necrosis, and more or less pronounced infiltration, attaining the size of the palm. Intracutaneous reinfection with these bacilli leads to a less extensive reaction but more pronounced infiltration (formation of a nodule). Intracutaneous injection of a suspension of bacilli (erysipeloidin) heated to 70°, into normal rabbits, produced only a very transient, minimal reaction; the toxin is thus thermolabile. Erysipeloidin injected into previously infected rabbits caused a cutaneous reaction corresponding to the reinfection reaction. There is thus a thermostabile factor which corresponds to diphtheria anatoxin. The immunobiological relations of the disease are analogous to the results obtained in other infectious diseases.—*From authors' summary (transl.).*

1488. JETTMAR, H. M. Beiträge sur Serologie des Yak- und Rinderblutes. *Zeitschr. Immunitätsforsch. u. Exp. Therap.* 65(3/4): 288-311. 1930.—3 groups were demonstrated in cows: aO, 26%; oA, 46%; and oO, 28%. In yaks, group aO was missing. Regularly occurring heteroagglutination of yak blood by cow serum was not demonstrable, but cow sera of the 1st group were found, which agglomerated yak and "hajnyk" corpuscles. Normal cow isoagglutinin worked slowly, being at a maximum in 12 hrs.; it was non-resistant to heat. Immune isoagglutinin was easily produced and very active.—*N. W. Larkum.*

1489. JIMENEZ, MARIA E. Sobre la existencia de una substancia especifica hidrocarbonada en B. perfringens. [A specific carbohydrate in B. perfringens.] *Rev. Soc. Argentina Biol.* 6(9/10): 571-572. 1930.—A precipitinogen can be isolated from *B. perfringens*, having the following chemical properties: with sodium alcohol acetate it gives a white gelatinous precipitate which precipitates intensely with specific sera. It gives a + Molisch test; a — biuret test; does not reduce Fehling's reagent but

does so after hydrolysis; contains N and resists boiling. It is therefore a nitrogenated carbohydrate.—*J. T. Lewis.*

1490. JOHANSSON, SVEN. I blodtransfusionsfrågan. (Summarisk redogörelse för 221 blodtransfusionsfall.) [Summary of 221 cases of blood transfusion.] *Hygiea [Stockholm]* 91(6): 209-239. 1929.—The author summarizes the results of his study on the risks of blood transfusion following satisfactory serological tests as showing among 313 transfusions 1 instance where the blood transfusion may have contributed to the fatal result, and 3 instances of temporary injury (2 showing rapid recovery, and 1 persisting for some time).—*Author's summary (transl. by G. I. Steffen).*

1491. JOKL, ERNST. Über Beeinflussung der immunbiologischen Normalstruktur des menschlichen Serums durch Körperarbeit. Das Verhalten der hämolytischen Kraft des aktiven Serums sowie des Normalhammelblutamboceptors im inaktivierten Serum. *Zeitschr. Ges. Neurol. u. Psychiatr.* 129(3/4): 460-471. 1930.—The investigations were carried out on 22 handball players, including both highly trained and very little trained men. Blood samples were taken before and after games. The hemolytic power of active serum was influenced but little by muscular activity, while, generally, the hemolytic normal amboceptor was distinctly increased. The observed phenomena are classified with the "emergency function of the sympathico-adrenal system (Cannon)."—*R. Koch.*

1492. KAMADA, KEIHO. Zur Diagnose und Bakteriologie der Banginfektion. *Zentralbl. Bakt. I. Abt. Orig.* 120(5/6): 364-376. 1931.—Comparative agglutination studies on the Bang bacillus, *B. typhi, B. paratyphi B,* and *B. dysenteriae* Shiga or Flexner, using 200 sera from parturients and gravidae (last stages). Sera from women advanced in pregnancy produced agglutination of Bang bacilli in a significant number of cases; but these sera also very frequently agglutinated other bacteria. Therefore (also because the sera frequently gave negative complement-binding reaction with *B. abortus*), the agglutination would appear to be non-specific (not produced by antigen-antibody reaction). It was very easy to produce strains of *B. abortus* divergent culturally, microscopically and serologically; but the virulence and immunizing action of these altered strains for guinea pigs, rats and white mice was unchanged. Immunity against infection was not attainable, but the fever following subcutaneous or intraperitoneal infection in guinea pigs could be prevented by immunization with suspensions of killed bacteria. Most of the artificially altered strains showed a tendency, after several passages in vitro, to revert to the original strain; reversion was frequent also in the bodies of infected animals. No infection of the fetus by the mother occurred in guinea pigs infected during the latter half of pregnancy, and no excretion of Bang bacilli in the milk was observed.

1493. KANDIBA, L., et E. SADOVSKY. Contribution à l'étude de l'antivirus; immunisation locale du poulain vis-à-vis du streptocoque. *Ann. Inst. Pasteur* 43 (12): 1637-1644. 1929.—Local as well as general immunity against streptococci is bound within strict quantitative limits. Experimental demonstration accordingly requires optimum qualitative conditions of test. Local immunization of cats and young horses allows innocuous injection into the organism of large quantities of living streptococci. The main active principle of Besredka's antivirus is a toxoid of the streptococcus toxin, possessing an easily manifested specific local immunizing power. The streptococcus toxoid is endowed with this property in a much higher degree than the non-specific proteins. The fresh toxin of streptococci has a capacity to aggravate the streptococcic infection. Therefore, the antivirus of Besredka is a specific toxoid. —*L. Kandiba.*

1494. KANDIBA, L., et E. SADOVSKI. Contribution à l'étude des toxines streptococciques. *Compt. Rend. Soc. Biol.* 100: 495-496. 1929.—By the bacteriotropic method of Neufeld it is comparatively easy to detect leukotoxic substances in the toxin of streptococci. The leukotoxic, as well as hemolytic, substances of the streptococcic toxin are present in young cultures only. They are extremely labile in respect to filtration, centrifugalization, thermic conditions and laboratory keeping qualities. The virulent streptococci do not possess in the same degree the power of leukotoxin production; this power nevertheless is connected with streptococcic virulence.—*L. Kandiba.*

1496. [KANDYBA, L. L., and I. ÏA. SADOVSKIĬ.] КАНДЫБА, Л. Л., и И. Я. САДОВСКИЙ. Стрептококковый токсин и антивирус. [Streptococcic toxin and antivirus.] Микробиологический Журнал Бактериологического Института имени Пастера (*Jour. Microbiol. Inst. Bact. Pasteur [Leningrad]*) 8(3): 221-233. [English summary.] 1929.—From experiments on local immunization of cats with streptococci, it is concluded that: the main active principle of Besredka's antivirus is a specific toxoid. Test on cats gave clear evidence of its immunizing power. Under certain conditions, the non-specific proteins and their derivatives possess the property to raise the resistance of the tissues against streptococci. This resistance in some cases is higher than that obtained by the action of specific streptococcic antigens.—*Authors' summary.*

1497. [KARETNIKOVA, V., and O. PODVYSOTSKAÏA.] КАРЕТНИКОВА, В., и О. ПОДВЫСОЦКАЯ. О туберкулезном антивирусе. [Tuberculosis antivirus.] [With French summary.] Вопросы Туберкулеза [*Voprosy Tuberkuleza*] 7(7): 778-780. 1929.—Old culture *Bacillus tuberculosis*, human type, was sown on 4% glycerin water containing large slices of potato (200 gm. per liter), and held for 4-6 weeks at 37° C.; then filtered through a Chamberland candle. Subcutaneous and intravenous injections of 2 cc. of filtrate into rabbits and guinea pigs provoked no reaction. Applied externally in lupus, antivirus caused improvement in 10 cases.—*B. Van Rosen.*

1498. KAWAMURA, H. Experimentelle Untersuchungen über Misch- und Sekundärinfektion. I. Ueber den Einfluss einer experimentellen Rekurrensinfektion auf eine Infektion mit andersartigen Rekurrensspirochäten oder mit Trypanosomen. *Zentralbl. Bakt. I. Abt. Orig.* 120(1/2): 59-78. 1931.—In mice infected with 2 different strains of relapsing fever spirochaetes, an alternating effect occurred, consisting of temporary exacerbation of one infection and temporary repression of the other, followed by reversal of the relations. This alternation was apparently not due to antagonism of the organisms, for great numbers of both frequently coexisted in the blood of a doubly infected mouse, and both persisted in the brain without regard to alternation of crises. In mice simultaneously or successively infected with relapsing fever spirochaetes and with nagana trypanosomes, a distinct prolongation of life (even in splenectomized or "blocked" mice) was observed as regards nagana infection. This effect on trypanosomiasis occurred only in the acute stage of relapsing fever. In mice infected in the last stages of relapsing fever, nagana ran its course as in normal mice; and if the relapsing fever was checked by treatment with solganal, its protective action ceased and the trypanosomiasis led to death within a few days. Inoculation of serum or transplantation of organs of mice or guinea pigs with relapsing fever, into nagana-infected mice, had no effect on the course of the trypanosomiasis. Since in mice infected with relapsing fever and nagana the trypanosomes from time to time invading the blood showed characteristics of recurrent strains, it must be assumed that the temporary repression and the resultant faltering course of nagana in doubly infected mice is caused by a non-specific heightening of the defensive reactions of the organism, called forth by relapsing fever and directed against the trypanosomes.—*Author's summary (transl.).*

1499. KEMP, TAGE. On the degree of agglutinability (sensitivity) of the blood corpuscles opposite isoagglutinins in human fetuses. *Acta Path. et Microbiol. Scandinavica Suppl.* 5: 62-63. 1930.

1500. **KERRIN, J. C. Studies on the haemolysin produced by atoxic strains of B. tetani.** *British Jour. Exp. Path.* 11(3): 153-157. 1930.—Atoxic strains of *B. tetani* secrete as powerful a hemolysin as do toxic strains. Normal serum and cholesterin exert a powerful antagonistic effect against tetanolysin, while lecithin has no antihemolytic power. The antihemolytic effect of normal serum is out of all proportion to its cholesterin content.—*J. Bland.*

1502. **KISSIN, D., und L. BRONSTEIN. Zur Frage der Bildung der Anatoxine. II. Ueber das Verhältnis des Amino-Stickstoffs in Diphtherietoxinen und -Anatoxinen.** *Zeitschr. Immunitätsforsch. u. Exp. Therap.* 66(3/4): 210-212. 1930.—Diphtheria toxin and anatoxin contain amino N. The slow change of toxin into anatoxin, which after months is still incomplete, is occasioned by a binding of 1 of the 2 NH_2 groups, which loses the properties of free NH_2. This is hastened by use of formaldehyde.—*N. W. Larkum.*

1503. **KLAUDER, JOSEPH V. (with the assistance of ANNA M. RULE, and BERNARD MADDEN). The humoral aspects of immunity to syphilis: with particular reference to the rôle of lipoids and the question of producing positive Wassermann reactions in rabbits.** *Arch. Dermatol. & Syphilol.* 23(5): 884-893. 1931.—To determine the spirochaeticidal action of the serum of syphilitic patients, 9 syphilitic rabbits were given intravenous, intramuscular, intraperitoneal and intratesticular injections of fresh pooled sera from syphilitic patients in various stages of the disease, but without therapeutic effects. Alcoholic extract of normal rabbit testicle and alcoholic extract of syphilitic rabbit testicle were separately injected into 4 normal rabbits; 1: 10 saline solution of hog serum was injected into 2 normal rabbits, and the same solution + a 6% suspension of cholesterol was injected into 2 other normal rabbits. The Wassermann reaction (Kolmer's technique) was, and remained, negative. These animals were then successfully inoculated with syphilis, and infection in no way differed from that in controls. Positive Wassermann reactions were obtained only when the rabbits had developed active syphilomas. These negative results do not support the theory of the presence of a lipoid antibody in the Wassermann reaction. The technique employed is of importance; it is asserted that investigators who report production of positive Wassermanns in rabbits by preliminary treatment such as that described do not mention the technique used.

1504. **KLUJEWA, N. G. Ueber den Einfluss der Galle auf die Agglutinabilität von atypischen Paratyphusbakterien.** *Zentralbl. Bakt. I. Abt. Orig.* 120(1/2): 34-40. 1931.—Of 46 cultures of intestinal bacteria, 20 were non-agglutinable strains, 14 spontaneously agglutinable, and 6 weakly agglutinable (not over 1: 100). Culture through 5 generations on filtered, sterile ox bile produced in some cases a distinct change in agglutinability. Some non-agglutinable and some spontaneously agglutinable strains were unchanged; in other cases, spontaneous agglutinability might appear in 1 generation, to disappear in the next. In many cases, however, agglutinability of non-agglutinable strains was unmistakably produced by culture on bile, and that of weakly agglutinable strains was distinctly raised, permitting their serologic differentiation.

1506. **KOLLER, S. Statistische Untersuchungen zur Theorie der Blutgruppen und zu ihrer Anwendung vor Gericht.** *Zeitschr. Rassenphysiol.* 3(3/4): 121-183. 1931.—This paper deals with several questions, but more particularly with the heredity of blood groups from a mathematical point of view. The author finds no relationship between blood groups and length of life. He discusses the hypothesis of Hirszfeld, that where father and mother belong to different blood groups (heterospecific pregnancy), offspring will more frequently inherit the maternal blood properties. He analyzes such families from material of several investigators and concludes that, on the whole, results do not deviate much from expectation according to the theory of heredity of blood groups. Discrepancies observed in the material of some workers are, he believes, due either to selection, illegitimacy, or faulty technique (examination of infants before blood group properties are fully developed, use of sera too weak in agglutinins). The author finds no difference in wt. of newborn from hetero- versus homospecific pregnancies. Hereditary properties in general, which could be used for paternity exclusion, and the heredity of factors M and N of Landsteiner and Levine, are discussed, and he finds, in agreement with Wiener, that, taking into consideration the 4 agglutinogens, A, B, M and N, exclusions can be made in about 33% of all cases. He mentions also the possible use of subgroups of group A (the heredity of which was studied by Landsteiner, Levine and Thomsen), and other hereditary properties, such as the occipital whorl.—*P. Levine.*

1510. **KUIPERS, F. C. Bijdrage tot de pathogenesis van de rattebeetziekte. [Pathogenesis of rat-bite fever.]** *Nederlandsch Tijdschr. Geneesk.* 73(11): 1346-1358. 1929.—The author examined the changes in distribution of white blood cells in a case of rat-bite fever. Because of the regularly returning anacritical rise in number of eosinophilic leucocytes, the critical fall and postcritical rise and the "calendar type" of the weekly attacks of fever, an attempt is made to explain the phenomena as a hyper-allergic reaction of the sensitized body against the *Spirillum* toxin. The qualities of local infiltration, its rapid appearance and disappearance, the violet-blue color, absence of suppuration, and occasionally occurring strictly localized necrosis with steep edges, all point to a reaction caused by supersensitiveness of the cutaneous vascular apparatus,—contraction of the small arteries coupled with expansion of the arterioles, the arterial and venous capillaries causing prestasis and eventually stasis. Disappearance of the local infiltration would thus be caused by local desensitization. The phenomena of exanthem, alternating muscular pains, absence of swollen spleen, curiously bloated face during attack, perhaps also the fever (anaphylactic fever), all can be explained more easily when regarded as hyperallergic rather than inflammation symptoms. Thus, here, one and the same toxin causes the same allergic reaction with people of varying constitutions (analogous with asthma epidemy of Frugoni, nickel eczema, ascaris asthma); the calen-

dar type occurs also with exudative diathesis (Assmann, Quincke, Thost), with some forms of angina with exanthem (Edel) and with empyema tuberculosa (author's observation). In analogy with these diseases which show a continual production of toxine, the author concludes that the periodical attacks are not caused by a cyclic change of *Spirillum minus*, but by the allergic reaction of the sensitized patient on the constantly produced *Spirillum* toxin.—*J. W. Langelaan.*

[Value of a flocculation reaction to formol in the cerebrospinal fluid in neurosyphilis.]** *Boll. Soc. Ital. Biol. Sperim.* 5(4): 498-499. 1930.—Positive responses were obtained with cerebrospinal fluid in neurosyphilis.—*M. Comel.*

1515. **LAUDA, E., und E. FLAUM. Studien über die Beziehungen der Milz zur Resistenz der Ratten gegen die infektiöse Anämie.** *Zeitschr. Ges. Exp. Med.* 73(3/4): 293-314. 1930.—Parabiosis was produced in 9 pairs of rats; 15 rats were superinfected to make sure of the presence of Bartonellas. One pair was discarded; of the remaining 8 pairs, 1 parabiont in each was splenectomized, and 14 days later, the other partner. In 6 of 8 cases, the single spleen sufficed to protect both parabionts from *Bartonella* anemia, as shown by blood counts and smears. Hence the authors conclude that the protective action of the spleen is not intracellularly but humorally exerted.

1516. **LE BOURDELLÈS, et P. SÉDALLIAN (préface par PAUL COURMONT). Précis d'immunologie. (Collection Testut.)** 920p. 4 col. pl., 20 fig. Gaston Doin et Cie: Paris, 1930. Price 95 fr.—This is one of a series of volumes on medical subjects edited under the direction of E. Forgue. The authors have made 3 chief divisions: general immunology, in which the general principles, theories and applications of immunity are discussed; specific immunity in infectious diseases; and, finally, the immunity processes of plants and animals. The subject is discussed largely from the viewpoint of general medicine. Technical problems are not considered in detail.—*L. C. Havens.*

1517. **LEDERMANN, K. G. Die Hodentuberkulinreaktion beim Meerschweinchen.** *Beitr. Klin. Tuberk. u. Spezif. Tuberk. Forsch.* 69(2): 265-272. 1928.—In agreement with observations by Long, the testes of tuberculous animals were found very sensitive to tuberculin. The sensitiveness is specific; its development sometimes precedes, sometimes follows, development of skin sensitiveness.—*L. Dienes.*

1518. **LEVINE, B. S. Theoretical considerations in connection with a cold incubation complement fixation test.** *Amer. Jour. Syph.* 15: 225-230. 1931.—Precipitation of the antigenic complex from colloidal suspension in serum is essential to complement fixation. Separation or conglomeration of the complexes as sensitized entities is firmer and more complete, though slower, at 8-10° C., due to the fact that phase augmentation and concomitant sensitization of antigen complex are reversible processes, more pronounced at 37.5° than at 8-10°. Since the antigen complex is not a specific immuno-chemical entity, it causes complement to be fixed in non-syphilitic sera as well. However, in the majority of syphilitic sera, the reaction-curves as a rule extend farther along the abscissa, and their crests are higher than in reaction curves of all other sera. Therefore, the general reaction can be conveniently divided into levels. The lower the reaction level, the greater the number, and the more varied the type, of sera that respond to the influence of the so-called antigenic reagent. By raising the level, a number of sera can be excluded. Theoretically, it would appear that diligent search might disclose a reaction level at which only syphilitic sera would be involved. However, since the intensity of any serum reaction is determined not only by type of immuno-reacting substances in the serum, but by concentration and by serum factors influencing dispersion as well, selection of a level at which all syphilitic, and at the same time only syphilitic, sera could be made to react is unattainable with present insufficient knowledge.—*B. S. Levine.*

1519. **LEVINSON, L. B., und E. E. GOLUBEWA. Ueber die Bedeutung des retikuloendothelialen Apparates bei Infektionskrankheiten. V. Die Rolle des retikuloendothelialen Apparates bei der Ausbildung der Immunität gegenüber Tetanus.** *Zeitschr. Immunitätsforsch. u. Exp. Therap.* 66(3/4): 204-212. 1930.—The reticulo-endothelial system takes no part in production of immunity against tetanus in white mice nor is the immunity increased by splenectomy. The method of immunizing was found to materially affect the results.—*N. W. Larkum.*

1525. **MALLICK, S. M. K., and M. L. AHUJA. Incidence of Brucella agglutinins in an average unselected Indian population.** *Indian Jour. Med. Res.* 18(3): 983-985. 1931.—The sera of 487 cases (healthy and febrile) were tested for *Brucella* agglutinins by Widal reaction. Both groups in certain percentages showed the presence of *Brucella* agglutinins.—*Authors' summary.*

1526. **MALLICK, S. M. K., and M. G. COOMBES. A short note on the agglutinogenetic powers of the "rough" and "smooth" variants of B. typhosus and their mutual immunological relationship. Pt. 2.** *Indian Jour. Med. Res.* 18(1): 143-148. 1930.—2 prophylactic vaccines were prepared, one from each variant. Another vaccine containing both variants in equal parts was also prepared. 3 batches of guinea pigs were immunized with each vaccine, the 1st receiving the smooth, the 2nd the

rough, and the 3rd the mixed. The immunity in each batch to infection by either variant was tested, demonstrating different immunological properties for the 2 variants.

1527. **MANWARING, W. H.** Renaissance of pre-Ehrlich immunology. *Jour. Immunol.* 19(2): 155-163. 1930.—Summarizing his experimental data on parenteral denaturization of alien proteins, the author concludes that there is convincing evidence that many injected antigens undergo chemical "hybridizations," or become semi-permanently "symbiotic" with animal tissues, the terms, of course, being used metaphorically. Some of these antigen-tissue "hybrids" have properties simulating those of specific "antibodies."—*W. H. Manwaring.*

1528. **MANWARING, W. H.** Biochemical relativity. *Science* 72(1854): 23-27. 1930.—Non-technical presentation of the basic postulate of post-Ehrlich immunology; a dynamic rather than a static specificity for tissue proteins, with environmental-protein hybrids the probable source of specific antibodies.—*W. H. Manwaring.*

1529. **MARRAS, ANTONIO.** L'enzimoreazione nello lepra. [Enzyme reaction in leprosy.] *Arch. Biol.* 5(6): 3-14. 1928.—The author reviews the theory of this reaction as enunciated by Sivori, viz., determination of quantity of immune bodies elaborated by the organism in defense against the morbific agent, as revealed by mixing patient's serum with specific antigen in presence of "ningestrin." Results were as follows: Tests were made on 29 cases, of which 5 were of tubercular type, 12 mixed, and 10 anesthetic and incipient. In the tubercular type and in 6 cases of mixed leprosy with tubercular form predominating, the reaction was constantly +. It was partial in the other 6 mixed cases; and partial in 8, − in 1 and + in 1 of the 10 anesthetic cases. Degree of + reaction varies directly with gravity of symptoms and inversely with duration of illness. The author recommends this reaction as of value in early diagnosis.—*A. Marras (transl. by P. Hillkowitz).*

1530. **MARTIN, LAY, and JUSTINA H. HILL.** Development of skin sensitization in guinea-pigs in response to intradermal injection of bacteria. *Bull. Johns Hopkins Hosp.* 46(3): 246-253. 1930.—Guinea pigs injected intradermally with emulsions of whole bacteria, both alive and dead (pneumococcus type I, *Streptococcus hemolyticus* and *Staphylococcus aureus* 209), developed skin sensitization to the same antigen within 48 hrs. So far as ascertained, this is the first time that this observation has been made. The skin sensitization remained for at least a month, but by that time had diminished. The strongest sensitization was developed about 10 days after primary inoculation.—*L. Martin.*

1531. **MASCHMANN, E., und E. KÜSTER.** Über die Gewinnung und Reinigung von Tuberkulin. *Zeitschr. Tuberk.* 59(4): 225-229. 1931.—Human type tubercle bacilli grown on Sauton's protein-free nutritive solution gave a tuberculin containing the specific agent, proteins of various molecular wts., and large amounts of carbohydrates. Purification (dialysis, acidification, adsorption on kaolin, solution in weak NH_3) gave a preparation 21 times as effective as the original; it showed all biuret and ninhydrin reactions, sometimes the Millon, but not the tryptophan or Molisch. The carbohydrate (glycogen), proteins precipitating at acid pH and those responsible for the Millon and tryptophan reactions are not essential to specific action.

1532. **MAXWELL, JAMES.** The intradermal tuberculin test. *Lancet* 219(5580): 289-291. 1930.—A standard method of performing the test is described, using 0.1 cc. of 1: 1000 dilution of Koch's Old Tuberculin, together with a control injection. The reaction is considered positive only when swelling occurs; erythema alone is insufficient. A positive result was obtained in 92% of the cases of proved tuberculosis tested, whereas positive reactions occurred in only 31% of the apparently non-tuberculous controls. A similar proportion of positive results was obtained in a series of cases of lymphadenoma. —*J. Maxwell.*

1533. **MAZZEO, MARIO.** Adrenalina e fenomeni immunitari. [Adrenalin and phenomena of immunity.] *Riforma Med.* 44(33): 1039-1042. 1928.—A group of rabbits was vaccinated against typhoid and examined for agglutination power. A 2nd group was vaccinated against typhoid and injected with 0.1% adrenalin. No difference in agglutination power was found, nor were precipitin or bacteriotropin influenced by adrenalin. The hemolitic power was increased by injection of ox blood corpuscles, but remained constant when the animals were treated with adrenalin.—*M. Goldstein.*

1534. **MAZZEO, MARIO.** Neutralizzazione della tossina dissenterica mediante la colesterina. [Neutralization of dysentery toxin by cholesterin.] *Riforma Med.* 44 (46): 1487-1491. 1928.—The author made 2 series of experiments as to the antitoxic power of cholesterin. Into rabbits of the 1st series, treated with cholesterin Merck, he injected dysentery toxin in different concentrations. They showed a modic neutralization of dysentery toxin. The 2nd series received an injection of ether-saturated solution of cholesterin Merck mixed with dysentery toxin in same proportion; these showed complete neutralization of the toxin.—*M. Goldstein.*

1535. **MELLI, GUIDO.** Osservazioni e ricerche sull' ipersensibilità con particolare riguardo all'asma bronchiale. [Hypersensitivity, with particular reference to bronchial asthma.] *Riforma Med.* 44(20): 582-586. 1928. —An important factor in bronchial asthma is the entrance of the anaphylactogen into the mucosa. Probably the so-called alimentary asthma is an asthma of inhalation. The author shows the importance of the entrance of anaphylactogen for setting in action the anaphylactic shock. He concludes that bronchial asthma is to be referred to the entrance of anaphylactogen into the bronchial mucosa. There is no doubt that in certain cases the entrance route differs, but in these cases also the bronchial mucosa has an important rôle in the asthmatic attack.—*M. Goldstein.*

1536. **MEYER, KURT, und HANS LOEWENTHAL.** Untersuchungen über Antikörperbildung in Gewebekulturen. [Investigations of antibody formation in tissue cultures.] *Zeitschr. Immunitätsforsch. u. Exp. Therap.* 54(5/6): 409-419. 1928.

1537. **MICHALOWSKY, ERNST-HEINRICH.** Tuberkulinempfindlichkeit tuberkulöser Meerschweinchen bei saurer Kost. *Zeitschr. Tuberk.* 59(5): 321-323. 1931.—After preliminary experiments on acid reaction in guinea pigs, an unstated number were inoculated with an emulsion of tubercle bacilli and at the end of 3 wks. ½ were placed on an acid diet of oats, oat flakes, and wheat bran, the others being kept on rape and hay. After 3 days, they were given intracutaneously 0.1 cc. of a 1: 5 solution of old tuberculin. The reaction was read in 48 hrs. and the animals were bled to determine the alkali reserve. A total of 34 results was obtained: 8 animals with acid reaction between 38.5-54.8 volume % showed greater reactions than 11 between 32.8-38-5 vol. %; 8 animals between 26.2-30.9 vol. % averaged greater reactions than the 11 weakly acid; 2 animals were alkalotic and showed slight reaction; and 5, extremely acidotic (18.5-25.2 vol. %), showed little reaction.

1538. **MILONE, SEBASTIANO.** La difesa del tessuto di granulazione contro l'infezione carbonchiosa in animali a digiuno, in avitaminosi e trattati con bleu trypan. [The defense by granulation tissue against anthrax infection in fasting animals, and in animals during avitaminosis and following trypan blue treatment.] *Arch. Sci. Med.* 54(9): 615-620. 1930.—Fasting, avitaminosis and blocking of the reticulo-endothelial system do not decrease the capacity of granulation tissue for protecting guinea pigs against anthrax infection.—*M. Comel.*

1539. **MISSORICI, A. PIAZZA.** Su una speciale reazione di diagnostica per i tumori maligni umani. [A special diagnostic reaction for human malignant tumors.] *Minerva Med.* 1(5): 165-167. 1930.—The author gives further experiences with the diagnostic reaction for cancer announced by Citelli and himself in 1928. It consists of a "hemoclastic crisis" produced by intravenous injection of small quantities of neoplastic vaccine. He

low reports positive results in 17 of 18 cancer cases (making altogether 46 cancer cases, with 91.3% positive results) and negative results in both of 2 controls (negative, 94% to date; total number of controls not stated).

1540. **MIZUNUMA, MASAHISA. On the group-specific lipoidophile antibody contained in the human sera of blood type O.** *Japanese Jour. Exp. Med.* 7(3): 341-361. 1929.—Type O (I) human serum contains an antibody which exhibits a specific complement fixation with alcoholic extract of Type A (II) or AB (IV) human blood corpuscles, and which differs from lipoidophil antibodies such as those of Wassermann or Forssman. The antigen for this antibody is contained in blood corpuscles of sheep and in organs of guinea pigs. The properties of the antibody cannot be distinguished from those of α-agglutinins. The possibility of a false positive Wassermann may be expected as a result of a reaction between A antigen and the author's antibody, although precipitation tests with these substances were not uniform.—*L. A. Barnes.*

1541. **MIZUNUMA, MASAHISA. The influence of the different resistance in the haemolysis of the ox red blood corpuscles on the result of the Wassermann reaction.** *Japanese Jour. Exp. Med.* 7(3): 363-377. 1929.—The susceptibility of ox erythrocytes to serum hemolysis differs according to individual characteristics, and is dependent on affinity of cells for hemolysin. This may cause serious errors in Wassermann reactions. Erythrocytes from healthy oxen are usually satisfactory, but those from animals with trypanosomiasis or other blood diseases are unsuitable.—*L. A. Barnes.*

1542. **MODERN, F., y RAÚL WERNICKE. Contribución al estudio del precipitado toxina-antitoxina diftérica. [Diphtheria toxin-antitoxin precipitation.]** *Rev. Soc. Argentina Biol.* 6(4): 241-250. 1930.—The toxin-antitoxin precipitate is completely soluble at pH 3.6; with less acidity it is incompletely soluble. If acidity is maintained, the toxin and antitoxin are dissociated, a maximum of antitoxin being recovered at pH 3.2-3.6, optimum temp. being 10-15° C. In some cases the ratio, antitoxin units: protein, has been 18 times that of the original serum.—*J. T. Lewis.*

1543. **MORELLI, ELISA. Sul passaggio di alcuni anticorpi normali dalla madre al feto. [Passage of normal antibodies from mother to embryo.]** *Sperimentale* 84 (5/6): 431-441. 1930.—The bactericidal power of guinea pig blood against cholera vibrios was increased in pregnancy but was not transmitted to the fetus. The hemolytic power of the blood of rabbits for pigeon erythrocytes was lessened during pregnancy and was lacking in newborn rabbits. The lack of such normal antibodies in fetus blood apparently was not related to deficiencies in activity of complement.—*Maud L. Menten.*

1548. **MUTERMILCH, S., et E. SALAMON. Sur la vaccination du lapin et du cobaye contre le tétanos cérébral.** *Ann. Inst. Pasteur [Paris]* 45(1): 85-101. 1930.—Subcutaneous or intraperitoneal vaccination of animals with tetanus anatoxin caused formation of tetanus antitoxin in the general circulation; the cerebrospinal fluid of the animals thus treated never contained antitoxin. Intrameningeal vaccination caused formation of antitoxin in the general circulation as well as in the cerebrospinal fluid. Actively or passively vaccinated guinea-pigs (subcutaneously or intraperitoneally) often resisted tetanus toxin inoculation into the brain; on the contrary, rabbits, in the majority of cases, appeared sensitive to this inoculation. Meningeally inoculated animals regularly appeared refractory to tetanus toxin inoculation into the brain. The presence of tetanus antitoxin in the cerebrospinal fluid is a condition "sine qua non" of the resistance of the neural axis of vaccinated animals. In meningeally vaccinated animals, this antitoxin is present in the fluid owing to its local formation, while in those vaccinated subcutaneously or intraperitoneally, antitoxin enters passively from the blood into the fluid, owing to a breaking down of the vasculomeningeal barrier, produced by injection into the brain of bouillon carrying tetanus toxin.—*Authors' summary (transl.).*

1549. **NAI, DINO D. On the nature of the thermoprecipitins.** *Jour. Immunol.* 19(3): 255-258. 1930.—The author concludes that small-flaking agglutinogens, thermostable precipitinogens, "residue antigens," and protein-free carbohydrate (specific soluble substance) may represent a single class of antigens. Their serologic reactions are parallel and their common characteristic is heat-stability.—*L. C. Havens.*

1550. **NEILL, JAMES M., LURLINE V. RICHARDSON, WILLIAM L. FLEMING, JOHN Y. SUGG, and EMIDIO L. GASPARI. Antidiphtheria group-agglutinin in the antisera of laboratory immunized animals.** *Amer. Jour. Hyg.* 13(2): 499-515. 1931.—The investigation dealt with a group-specific antibody recognizable by agglutination of a "degraded" strain of diphtheria bacilli. Group-agglutinin was present in antisera of laboratory animals immunized with bacterial vaccines of different strains of diphtheria bacilli or of some diphtheroids; it was likewise produced by immunization with soluble bacterial material containing no formed cells. Antisera of laboratory immunized animals were studied to establish facts useful in interpretation of antidiphtheria antibodies in human sera. The most important facts were that group-agglutinin is immunologically specific to the diphtheria-diphtheroid group and that it represents antidiphtheria antibodies of a sort differing from antitoxin antibody. Presence of group-agglutinin in serum can be considered to depend on previous immunization with diphtheria bacilli or with serologically related diphtheroids. Because of the broader immunological range of group-specific rather than "type"- or "strain-specific" serological reactions, and because of its apparent quantitative suitability for tests of sera of low antibody content, the group-agglutinin test appears well fitted for examination of human sera for antidiphtheria antibodies other than antitoxin.—*Authors' summary.*

1551. **NEILL, JAMES M., WILLIAM L. FLEMING, and LURLINE V. RICHARDSON. Antidiphtheria group-agglutinin in the sera of adult people.** *Amer. Jour. Hyg.* 13(2): 516-531. 1931.—Sera of adults were tested for presence of the antidiphtheria group-agglutinin reported by Neill, Richardson, Fleming, Sugg, and Gaspari (see this issue, entry 1550). Of 1,030 adults who had received no diphtheria immunization other than that afforded by the usual naturally-occurring contacts, a large pro-

portion agglutinated the P diphtheria strain. As might be expected, the % of agglutinators varied with dilution of serum: 24% gave definite agglutination at 1:10 dilution; 8.6%, at 1:50 or higher. In tests of a smaller group (267) with low dilutions, 76% agglutinated the diphtheria strain at 1:2. Results showed that large numbers of adults possess diphtheria antibodies of the antibacterial type, like those found in antisera of laboratory animals immunized with diphtheric material. While there is no knowledge of actual immunization of those of the test group, 2 other persons immunized under known conditions with diphtheric material (1 with vaccine; the other with formolized filtrate) were found to produce the agglutinin. Other facts in support of the immunological nature of antidiphtheria agglutinin in human serum were that it is heat-stable (55° C.) and that it can be specifically removed from serum by absorption with suspensions of diphtheria bacilli.—*Authors' summary.*

1552. NEILL, JAMES M., WILLIAM L. FLEMING, and EMIDIO L. GASPARI. Individual persons with high levels of antidiphtheria group-agglutinin. *Amer. Jour. Hyg.* 13(2): 532-543. 1931.—A group of 5 adults with an unusual amount of the antibacterial type (group-agglutinin) of diphtheria immunity were studied over a period of 30 mo. to 4 yrs. In most instances, those with a high level of group-agglutinin in the 1st test, maintained this high level throughout the study. When considered as a group instead of as individuals, adults with an unusual degree of antibacterial immunity also had unusual degrees of the other types of diphtheria immunity, as shown by the high average antitoxin content of the sera and by the greater tendency to give diphtheria-hypersensitive skin reactions. Those maintaining a level of antibacterial immunity higher than that of the usual adult may do so not because of greater contact with the bacteria, but because of an inherent capacity to respond to antigenic stimuli that would be insufficient for the ordinary person.—*From authors' summary.*

1556. NIKOLAEFF, N. M., und L. L. GOLDBERG. Über Verhütung des experimentellen anaphylaktischen Shocks. III. *Zeitschr. Ges. Exp. Med.* 73(3/4): 475-480. 1930.—These experiments were based on the theory that anaphylactic shock can be prevented by depressing the adsorptive capacity of the reticulo-endothelial cells. Of 15 guinea pigs, all were sensitized; 4 received injections of Congo red (3 intraperitoneally, 1 subcutaneously); 3, subcutaneous injections of quinin hydrochlorid; 3, intraperitoneal injections of trypan blue; and 5 were kept as controls; all were then given 2nd antigen injections. Congo red and trypan blue either prevented or lightened shock; the quinin in 10% concentration intensified shock, and 1% or lower strength, weakened it. It is concluded that anaphylaxis depends on energetic adsorption of protein split-products by the erythrocytes, which thereby become more readily subject to phagocytosis; and on a lowered capacity of the reticulo-endothelial system to render harmless the antigen adsorbed by the erythrocytes.

1557. NIÑO, FLAVIO. Ensayos de inmunización anticriptocócica en los animales de laboratorio. [Cryptococcus-immunization of laboratory animals.] *Quinta Reunión Soc. Argentina Patol. Reg.* 1: 156-171. 13 fig. 1930. By inoculating increasing doses of killed and living cultures of *Cryptococcus psicrofilicus* Niño 1929 into laboratory animals, a clear-cut immunization against this microorganism was obtained. On the contrary, no specific protection followed either serum treatment or serum prevention of the experimental disease.—*A. de Assis.*

1558. NISHIO, MASAO. Über das Wesen des Reagins der Wassermann Reaktion und die Unentbehrlichkeit der Elektrolyten für die Sachs-Georgische Reaktion. *Sei-I-Kwai Med. Jour.* 47(2): Japanese 10-39: German summary, 2-3. 1928.—The author used cerebrospinal fluids from syphilitics and non-syphilitics and a reagin isolated from syphilitic sera. His results oppose the views of Hartly (1925) in that the reacting substances are lipoids and the salt content has a great influence on the Sachs-Georgi reaction. Without the presence of these salts the reaction does not occur.—*K. R. Collins.*

1559. OHAMA, S. Experimental studies on phagocytosis by neutrophile leucocytes. Taiwan Igakki Zasshi. [*Jour. Med. Assoc. Formosa*] 309. 82. 1930.—The phagocytic action of neutrophilic leucocytes, for dead staphylococci in a guinea pig was most pronounced 30 min. after injection. Arneth's types 2 and 3 were most conspicuous in this process. 2 hrs. after injection the number of neutrophiles reached their maximum and the action became greatly reduced.—*E. C. Faust.*

1560. OHSHIRO, S. Studies on the diagnostic value of the agglutination test. Comparison of quantity of agglutinins of Japanese in Formosa with that of Formosan Chinese. *Taiwan Igakkai Zasshi.* [*Jour. Med. Assoc. Formosa*] 306. 49. 1930.—In 624 cases studied, specific agglutinins were found to be much higher in Formosan Chinese than in Japanese, while the reverse was true in the non-specific agglutinins.—*E. C. Faust.*

1561. OHYA, K. Über die Wirkung einiger Aldehyde und Benzolderivate auf Gifte und Agglutinine pflanzlicher Herkunft und auf Schlangengift. *Zeitschr. Immunitätsforsch.* 64(3/4): 270-285. 1929.—Formaldehyde (HCOH) affects ricin at 36° to the extent that mice survive 600 m.l.d. Local necrotic action remains with the larger doses. With increase in HCOH concentration, detoxication proceeds more rapidly. Under similar conditions *o*-hydroxy benzaldehyde and phenol have no effect on ricin. Mice could be immunized with ricin toxoid, degree of immunity depending on number of toxoid injections. The eye-irritant action of ricin in rabbits was also destroyed by HCOH, but only weak local immunity could be produced by toxoid. The agglutinative function of ricin is more resistant to HCOH action than is the toxic function. The agglutinin was unaffected by *o*-hydroxy benzaldehyde and phenol, while partial or complete destruction was obtained by HCOH. The non-toxic agglutinin from bean seed is destroyed by HCOH, but not by *o*-hydroxy benzaldehyde or phenol; that of potato tubers is affected by phenol as well, but not by *o*-hydroxy benzaldehyde. The venom of the Habu snake was detoxicated by HCOH, furfural, *o*-hydroxy benzaldehyde, Na salicylate, Na benzoate, and phenol. The immunity produced by HCOH toxoid was low and depended on concentration of venom solution used in preparation. Furfural toxoid produced a higher degree of immunity.—*L. W. Butz.*

1562. OHYA, K. Zur Frage der Atoxizität und des immunisierenden Effektes von Tetanusanatoxin. *Zeitschr. Immunitätsforsch.* 64(3/4): 286-293. 1929.—Mice received 2 separate injections of varying amounts of anatoxin. After 3 weeks, the antitoxin content of the blood was determined by mixing blood samples with fresh precipitated toxin, incubating for ½ hr., and injecting. In general, mice receiving the most anatoxin had the highest antitoxin content, but there was con-

siderable individual variation. On testing immunized mice it was found that degree of immunity was directly related to antitoxin content. On the average, mice showed high immunity after anatoxin treatment. This may have been due to the high toxicity of the tetanus toxin used in preparing the anatoxin.—*L. W. Butz.*

1563. **OMODEI SATE, CESARE. Sul fenomeno dell'anacoresi. VIII. L'anachoresi nei virus filtrabili. [Studies on anachoresis. VIII. Anachoresis and filterable viruses.]** *Biochim. e Terapia Sperim.* 17(8): 344-361. 1930.—Anachoresis is shown also in infections by filterable viruses. In guinea pigs infected by foot-and-mouth disease virus, if injected subcutaneously with BCG, the filterable virus is found present in the subcutaneous tuberculous nodules at 12 hrs. to 7 days. This 1st stage of anachoresis is followed by the extinction of the virus; after the 7th day it is no longer present in the nodules. These experiments corroborate those previously made with other filterable viruses.—*M. Comel.*

1564. **OTTO, R., und G. BLUMENTHAL. Weitere tierexperimentelle Beiträge zur aktiven Immunisierung gegen Diphtherie.** *Zeitschr. Hyg. u. Infektionskr.* 111(3): 380-386. 1930.—2 formol-toxoids made from a potent diphtheria toxin possessed good immunizing qualities. Guinea pigs immunized with 3 subcutaneous doses of 1 cc. gave a high antitoxin titer and were protected against many lethal doses of toxin. 10 animals treated by Löwenstein's method showed a low antitoxin titer and practically no immunity against toxin.—*Authors' summary (transl. by A. F. Reith).*

1568. **PHILLIPS, G. E. The blood groups of the Maori.** *Human Biol.* 3(2): 282-287. 1931.—200 individuals selected at random from 8 Maori tribes of New Zealand were classified into the 4 blood groups of Moss by means of known sera collected from whites. Results were as follows: Group 4, 47.5%; 3, 1%; 2, 39.5%; 1, 12%. All members of Group 1 and 1 of the 2 members of Group 2 belonged to the Arawa tribe. Certain of these individuals were characterized by the fairer skins and reddish tinted hair of the aboriginal Maoriri stock of New Zealand. Since agglutinogen B is a dominant Mendelian characteristic, it is impossible for Group 1 to be larger than 3, and consequently it is suggested that the pure Maori race does not contain the B-b agglutination system and that this system has been introduced into the blood of certain individuals by miscegenation with aboriginal Maoriri stock.—*G. E. Phillips.*

1569. **PHILPOTT, CHARLES H. Effect of toxins and venoms on Protozoa.** *Jour. Exp. Zool.* 56(2): 167-184. 1930.—Under the conditions used, botulinus tetanus and ricin toxins had no effect on *Paramecium caudatum;* venom of 8 snakes was found, however, to be highly toxic for paramecia. From a study of the effect of *Crotalus atrox* venom on 11 species of protozoa, it appears that some are more susceptible to the fatal action of venom than others. The agent lethal to protozoa is thermolabile and neutralized by *Crotalus* antivenin. Paramecia were used as test animals in titrating the potency of venoms. Repeated titrations, in which paramecia were used as test animals, showed small variation in results for each venom. In these titrations the minimal lethal dose is defined as the smallest amount of venom per cc. of medium per animal required to kill paramecia within 24 hrs. Paramecia were also used in titrating the potency of *Crotalus* antivenin, but the titer thus obtained did not correspond to that obtained when warm-blooded animals were used. The agent responsible for the lethal action of venoms on paramecia is not the same in all venoms. In *Crotalus* venoms the agent seems to correspond to hemorrhagin; in *Cobra* venom, to neurotoxin, according to Noguchi's classification of the toxic constituents of venoms.—*C. H. Philpott.*

1570. **PINCUSSEN, LUDWIG. Das Verhalten der Blutphagozyten von bestrahlten Meerschweinchen.** *Strahlentherapie* 39(1): 103-108. 1930.—Guinea pigs were irradiated with a quartz lamp for 15 and 30 min.; with a Vitalux lamp for 30 min., or for 2 periods of 30 min. each, at a 1 hr. interval; or, for 30 min. with a Vitalux lamp for which the invisible light and the shorter-waved visible light as far as the green had been eliminated. There was a rise in rectal temp. in all,—slight with the quartz light, pronounced with Vitalux. Smears were made before, and 1 and 2 hrs. after, irradiation, for phagocytosis. After standing 1 hr. at 37° no increase in phagocytosis was observed from irradiation with the quartz light, but a 33-100% increase with the Vitalux. After removal of the warm rays from the Vitalux lamp, 30 min. irradiation had no effect; irradiation with heat but not light rays had the same effect as with heat and visible light. Thus, it is warmth which promotes phagocytosis.

1571. **PODESTÀ, G. B. La deviazione del complemento nella infezione blenorragica. [Deviation of complement in gonorrhea.]** *Riforma Med.* 44(3): 51-54. 1928.—The author examined 125 cases of gonorrhea, using different antigens (gonargin, artigon, gonococcus emulsion), and found (by deviation of complement) in the gonorrheic organism specific antibodies, mostly between the 20th and 70th days of the disease, and especially in severe and in complicated cases. Uncertain results are to be found in latent infections.—*M. Goldstein.*

1572. **PONZI, ETTORE. Sulla presenza delle isoagglutinine nel colostro. [Isoagglutinins in colostrum.]** *Riv. Ostetr. e Ginec. Prat.* 11(12): 19-25. 1929.—The same isoagglutinins are found in colostrum as in blood serum, and the 4 groups behave in the same way. Many phenomena of pseudo-agglutination complicate the study.—*E. Ponzi (transl. by P. Popenoe).*

1573. **PONZI, E. Contributo agli studi sui gruppi sanguigni. [Blood groups.]** *Ateneo Parmense* 2(6): 584-602. 1930.—Results of 1220 determinations of blood groups in Parma, Italy, give a biochemical index of 3.7 for the Province. In the study of 220 newborn infants and their parents, no exception to Bernstein's hereditary formula was noted, nor was confirmation furnished of Hirszfeld's hypothesis of a greater fetal development in homospecific pregnancy. No relation was found between icterus neonatorum and blood group or between diminution in wt. during the 1st days of life and serologic difference between mother and child. The author believes that no absolute value can be assigned to the results of Kemp, who found agglutinogens regularly present by the end of the 3rd month of fetal life.—*Author's summary (transl.).*

1574. **POUSMA, R. H. Report of four cases of rattlesnake bite.** *Bull. Antivenin Inst. America.* 2(3): 61-63. 1928.—Record of poisonings by rattlesnake bites (probably *Crotalus atrox),* showing antivenin to be the best means of treatment.—*A. do Amaral.*

1580. **RAMON, G., et ROBERT DEBRÉ.** Sur la teneur en antitoxine spécifique du sérum des sujets vaccinés par l'anatoxine diphtérique. *Ann. Inst. Pasteur* [*Paris*] 45(3): 326-336. 1930.—Of 105 sera of children vaccinated 1, 2, 3 and 4 yrs. previously, 95 had an antitoxic power of more than 0.1 unit; of these, 43 had an antitoxic power greater than 1. Among the sera of children vaccinated 3 and 4 yrs. previously, 95% had a protective amount of antitoxin; 89% of those vaccinated 2 yrs., and 82% of those vaccinated 1 yr. previously, displayed protective amounts of antitoxin, indicating that immunity produced by anatoxin is not temporary.

1581. **RAMSDELL, SUSAN GRIFFITH.** The reaction of the human skin to normal and immune guinea pig serum. *Jour. Immunol.* 19(2): 217-221. 1930.—The human skin reacts rather regularly, with the immediate type of reaction, to normal guinea pig serum at dilution 1: 10, and to a lesser degree at 1: 50. Usually, after this reaction, the skin becomes normal in appearance in 2-24 hrs. When an anti-human serum at dilution 1: 10 is injected, the immediate reaction is not always greater than that due to normal serum. But a difference is made more evident by using higher dilutions of sera, indicating a specific antigen-antibody response. A further difference in reactions is seen in the persistence of that to the immune serum, with induration and inflammation for 24 hrs. The degree of reaction, with both sera, is only slightly reduced by heating the sera for 10 min. at 50°C. —*Author's summary.*

1582. **RAMSDELL, SUSAN GRIFFITH.** The transfer of the skin-reacting antibody in human serum to guinea pig skin. *Jour. Immunol.* 19(5): 411-416. 1930.—A specific reaction in the guinea pig skin may be obtained with fair regularity, where the test-antigen can be used in a considerable concentration, on transfer of the serum of asthmatic subjects to the animal skin. The sera of hay-fever, urticarial, and eczematous patients only occasionally transfer this reaction. This failure is ascribed to a relatively low antibody content in such sera and to the limitations of the technic used.—*Author's summary.*

1583. **REICHEL, H. J.** Die Müller-Ballungs-Reaktion im Liquor. *Zentralbl. Bakt. I. Abt. Orig.* 116(4/5): 347-349. 1930.—In the cerebrospinal fluids of 250 non-syphilitic cases the specificity of the Müller conglobation reaction was tested against the Wassermann, the 2 agreeing in 95.6% of cases. Used in 250 lumbar punctures on syphilitic cases, the tests agreed in 91.6% of cases. The Wassermann alone was positive in 4.8%; the Müller alone, in 3.2%.

1584. **REICHEL, H. J.** Die Meinicke-Klärungsreaktion auf Syphilis. *Zentralbl. Bakt. I. Abt. Orig.* 116(4/5): 349-352. 1930.—Tested on 412 sera from non-syphilitics, the Meinicke clarification reaction gave 3.4% positive reactions. On 588 sera from known syphilitics, the Meinicke clarification test gave a higher number (383, or 65.1%) of positive results than the Wassermann (188, or 31.99%) or the Meinicke clouding reaction (317, or 53.84%), and nearly as high as the Müller conglobation reaction (393, or 66.84%). The exceptionally large number of negative results is attributed to the fact that many of the cases had already been long under treatment.

1585. **RIEHM, W.** Über experimentelle anaphylaktische Keratokonjunktivitis am Kaninchenauge, zugleich ein Beitrag zur Auffassung über die Ätiologie der skrofulösen Augenentzündung. [Experimental anaphylactic keratoconjunctivitis in the rabbit eye, as well as a contribution to the etiology of scrofulous eye inflammation.] *Arch. Augenheilk.* 99(3): 438-500. 16 fig. 1928.

1586. **RITOSSA, PIO, e ALBERTO OBERHOLTZER.** Ricerche sperimentali sui sieri leucolitici. [Studies on leucolytic sera.] *Riv. Patol. Sperim.* 5(4/5): 290-305. 1930.—Repeated injections of human and guinea pig leucocytes provoked in rabbits the appearance in serum of substances having a lytic action towards leucocytes of the inoculated species and, in smaller degree, towards leucocytes of other species. This activity may be determined in vitro. Serum of treated rabbits injected into guinea pigs provoked destruction of leucocytes and leucopenia. A toxic action, often lethal, followed when guinea pigs were injected with serum sensitized to guinea pig leucocytes.—*M. Comel.*

1587. **ROSENAU, M. J., and H. B. ANDERVONT.** Vaccinia: susceptibility of mice and immunologic studies. *Amer. Jour. Hyg.* 13(3): 728-740. 1931.—Attempts to vaccinate mice on the skin of the abdomen were apparently unsuccessful. Virus was found within the skin for at least 6 days after vaccination, but this was possibly survival, and not necessarily successful vaccination. The fact that lesions of the smallpox papule and vesicle are mainly confined to the epithelial layer, suggested that possibly the extremely thin layer over the mouse's abdomen might not supply material for pronounced vesiculation. Experiments (15) were performed, in which 86 mice were vaccinated on the pads of the feet where the epidermis is thick; 59 showed typical "takes" visible to the naked eye. Vaccination on the thick epidermis near the root of the tail also produced vesicles, confirming the view that thickness of epithelial layer is responsible for visible reaction. Mice vaccinated (apparently unsuccessfully) on the abdominal skin were subsequently immune to pad vaccination, clearly indicating that infection had taken place, even when no visible evidence of skin reaction could be discerned. In another series it was demonstrated for the 1st time that mice are susceptible to vaccinia by inoculating virus into the brain; this was true, however, only for an especially virulent strain. The virus was carried through 28 mouse-brain passages extending over 6 mo. and it was shown that vaccine virus was responsible for the symptoms observed, by cross immunity tests with rabbit neurovaccine and calf dermovaccine. Brains of mice, after intracranial inoculation of vaccine virus,

failed to reveal lesions described as characteristic of vaccinal encephalitis.

1588. ROSENBLÜTH, ALEXANDER. Zur Diphtherieprophylaxe mittels der Schutzsalbe nach E. Löwenstein. *Zeitschr. Kinderheilk.* 50(6): 775-780. 1931.—Of 290 boys 11-18 yrs. old, 148 were Schick-negative, 142 positive. 3 inunctions with Löwenstein's ointment were made at 14-day intervals in 120 positives; of these 43 (36%) were negative, 77 (64%) positive 50 days after the 1st and 22 days after the 3rd inunction; of 108, 35 (32.5%) were negative and 73 (67.5%) positive 6 mo. after the 1st and 5 mo. after the 3rd inunction.

1589. RUBINO, M. C. Untersuchungen zur Verwendung formolfixierter Hammelblutkörperchen in der Serodiagnostik. *Zentralbl. Bakt. I. Abt. Orig.* 120(5/6): 378-384. 1931.—The author succeeded in producing fixation of sheep erythrocytes by formalin so that their histologic characters were unaltered, but they were non-hemolyzable either by distilled water or by specific amboceptor in presence of complement. These fixed erythrocytes preserved their antigenic properties and produced hemolysins and agglutinins in rabbits. They retained the capacity (but in less degree than in normal erythrocytes) to absorb specific amboceptor; addition of active human serum was productive of marked rise in absorptive capacity toward specific amboceptor. Treatment of active human serum by these fixed erythrocytes resulted in absorption of normal amboceptor and inactivation of complement, a process in which the relative proportion of concentration of serum and of suspension of formalin-fixed corpuscles plays a rôle; the amount of normal amboceptor is also significant. Sensitized, formalinized sheep erythrocytes have a greater absorptive capacity toward complement than the non-sensitized.—*Author's summary (transl.).*

1590. SAITO, TAISHIN. Über die Verwertbarkeit der Kahnschen Reaktion für die Serumdiagnostik der experimentellen Kaninchensyphilis. *Zeitschr. Hyg. u. Infektionskr.* 110(4): 603-617. 18 fig. 1929.—The Kahn reaction has little sensitiveness to non-specific inhibiting substances in rabbit serum as compared with complement fixation. The Kahn test furnishes distinctly negative reactions with normal rabbit serum, with extremely rare exceptions, and gives clearly positive reactions with serum from rabbits inoculated with luetic material; it apparently offers a reliable means for recognition and observation of experimental rabbit syphilis.—*P. G Heineman.*

1591. SAVINO, ENRIQUE. Manera de seleccionar a los animales durante la immunización con toxina diftérica. [Selection of horses for diphtheria antitoxin production.] *Rev. Soc. Argentina Biol.* 6(7/8): 482-490. 1930.—Final titers of more than 200 units per cc. were considered high. Of 116 horses 61% gave high titers. Animals giving titers of only 50-100 units per cc. after injection of 75-100 cc. should be eliminated. This proceeding reduces the final low titers to 6%.—*J. T. Lewis.*

1592. SAVINO, ENRIQUE. Aplicación del cálculo de probabilidades al estudio de la inmunización de caballos inyectados con toxina diftérica. [Distribution of titers in horses immunized with diphtheria toxin.] *Rev. Soc. Argentina Biol.* 6(7/8): 491-495. 1930.—Applying the probability calculus to the antitoxin titers of sera from 146 immunized horses, it was found that in animals with 100-350 or with 550-800 units per cc., the distribution curve is above the calculated value; it is below for animals with 0-100 or 350-550 units per cc.—*J. T. Lewis.*

1593. SAVINO, ENRIQUE. Distribución de los valores de los caballos inmunizados con toxina tetánica. Probability calculus applied to tetanus immunization in horses.] *Rev. Soc. Argentina Biol.* 6(9/10): 587-592. 1930.—The distribution of values curve as found in 131 horses does not correspond to the calculated curve. High values are greater than those calculated and low values fall below the calculated curve.—*J. T. Lewis.*

1594. SCHILLING, CLAUS. Pathologisch-histologische Studien in Bezug auf den Calmetteschen Tuberkelbacillus (B. C. G.). *Virchow's Arch. Path. Anat. u. Physiol.* 278 (2): 462-476. 14 fig. 1930.—Of 21 guinea pigs, 15 received intravenous or intracardiac injections of suspensions of BCG; and 11 of the latter were killed 7-69 days after infection. The lungs showed macroscopically recognizable tubercles in which bacilli multiplied and formed homogeneous clumps, with formation of pigment. While these tubercles showed a tendency to shrivel and disappear, and the bacilli in later stages ceased to be acid-fast, the author believes that BCG cannot be called avirulent, since the bacilli multiply in the organism and produce pathologic changes, including slight necrosis. The remaining 4 BCG-infected guinea pigs, together with the 6 controls, received intravenous injections of virulent tubercle bacilli, and were killed 7-29 days later. Within this time no multiplication of superinfecting bacilli and no formation of typical tubercles was observed, but at most a somewhat focal inflammation of the pulmonary supporting tissue with progressive involvement of the alveolar epithelium (interstitial pneumonia). Therefore is is believed that a considerable antigenic action against subsequent virulent infection, within the period of 29 days, cannot be denied to BCG.

1595. SCHIMANKO, J. Die biologischen Grundlagen der Behandlung der Hauttuberkulose. *Arch. Dermatol. u. Syph.* 162(2): 442-449. 1930.—The various phases of cutaneous tuberculosis parallel the varying degrees of cutaneous sensitization. The disease is an allergic reaction of the highly sensitized skin, as is shown by a much higher percentage of Pirquet positives in 650 cases of cutaneous, than in 371 cases of pulmonary tuberculosis. The degree of allergic reaction is indicative of the extent of the disease or recovery therefrom.

1596. SCHLOSSBERGER, H. Über den gegenwärtigen Stand der Blutgruppenforschung. *Reichs-Gesundheitsbl.* 4(13): 283-288. 1929.—A survey of the development and results of blood-group investigations and their application to clinical and forensic medicine and to anthropology.—*H. Schlossberger (transl.).*

1597. SCHMIDT, ADAM. Blutgruppenbestimmungen an der Batschkaer Bevölkerung. [Studies on blood groups among the Batschka people (Jugoslavia).] *Zeitschr. Rassenphysiol.* 3(3): 57-66. 1930.

1598. SCHMIDT, S. Toxines et antitoxines: constitution et mode d'union. *Ann. Inst. Pasteur [Paris]* 45(3): 337-372. 1930.—A review of the theory.

1599. SCHÖBL, OTTO, BUNSHIRO TANABE, and ISAO MIYAO. Preventive immunization against treponematous infections and experiments which indicate the possibility of antitreponematous immunization. *Philippine Jour. Sci.* 42(2): 219-237. 1930.—Vaccination of monkeys by subcutaneous injection with killed frambesia treponemas was followed by rapid development of immunity to yaws, of long duration. This immunity also prevented development of the specific lesion following syphilitic infection, but did not prevent penetration of the treponemas into the regional lymph nodes.—*L. C. Havens.*

1600. SCHRADER, G. Untersuchungen zur Frage der Blutgruppenänderung. *Zeitschr. Rassenphysiol.* 3(3/4): 108-116. 1931.—Repeated examination of 142 patients subjected to non-specific therapy (malaria, gonococcus vaccine) gave no evidence for assuming a change of blood group. In 3 of 64 cases there was a considerable increase of agglutinin content when examined at intervals of 3-12 wks.—*P. Levine.*

1601. SCHÜTZE, W. Über Intrakutanreaktionen bei Fällen von Syphilis und Nichtsyphilis mit Spirotest und Rückenmarksflüssigkeit. [Intracutaneous reactions in syphilitic and non-syphilitic cases with spirotest and cerebrospinal fluid.] *Dermatol. Wochenschr.* 90(14): 485-488. 1930.—Spirotest (said to consist of killed spirochaetes of syphilis in physiologic saline with 0.5% phenol) was tried on 124 cases, of which 26 were syphilitic, and cerebrospinal fluid on 116 cases, of which 72 were syphilitic. Neither test gave reliable results.

1602. SELLERS, T. F., and JANIE F. MORRIS. The comminution of blood clots for cultures. *Amer. Jour.*

Publ. Health. 20(2): 195-196. 1930.—Whole blood sent for examination by agglutination tests for typhoid, typhus, undulant fever, tularemia, etc., after removal of serum, is comminuted by forcing through a sterilized Luer syringe into the medium.

1603. **SELTER, H. Die bisherigen Ergebnisse der Tuberkulose-Immunisierungsversuche an Meerschweinchen.** *Zeitschr. Immunitätsforsch. u. Exp. Therap.* 66 (3/4): 351-366. 1930.—On the basis of relatively few guinea pig experiments it is claimed that successful immunization against tuberculosis can be obtained by injections of organisms having a weakened virulence. Such strains produce a local infection either at site of inoculation or in regional lymph nodes. They do not result in generalized infection. Avirulent or killed organisms give only increased resistance and serve only to prolong the life of the individual against succeeding infection. With strains of reduced virulence the immunity begins only when the local lesion commences to heal.—*N. W. Larkum.*

1604. **LANGE, BRUNO. Die bisherigen Ergebnisse der Tuberkulose-Immunisierungsversuche an Meerschweinchen.** *Zeitschr. Immunitätsforsch. u. Exp. Therap.* 66 (3/4): 367-376. 1930.—A reply to Selter's contribution, in which the author takes exception to Selter's conclusions on the ground that no control of the number of living organisms is made. He denies the validity of Selter's conclusions throughout. [See Entry 1603.]—*N. W. Larkum.*

1605. **SELTER, H. Schlussbemerkung zu der Erwiderung Langes.** *Zeitschr. Immunitätsforsch. u. Exp. Therap.* 66(3/4): 377-379. 1930.—The author defends his position on tuberculosis immunization in reply to Lange. [See Entry 1604.]—*N. W. Larkum.*

1606. **SERENI, ENRICO. Ricerche sulla anafilassi. VIII. A proposito di anafilassi e avitaminosi. [Anaphylaxis and avitaminosis.]** *Riv. Patol. Sperim.* 5(2/3): 252-257. 1930.—Animals kept on avitaminosis diet show more intense anaphylactic shock than those on normal diet. Avitaminosis increases the sensitivity to the agent causing anaphylaxis; delayed production of antibodies may also be involved.—*M. Comel.*

1607. **SIERAKOWSKI, S., und MELZAK. Einfluss der verschiedenen pH auf das Ergebnis der Sachs-Georgi Reaktion.** *Zentralbl. Bakt. I. Abt. Orig.* 118(5/6): 366-373. 1930.—The Sachs-Georgi reaction is strongest with antigens at pH 5.8-7, serum pH remaining unchanged. Negative sera become positive at pH 5; positive sera become negative at pH 9. Best results were obtained by diluting Sachs-Georgi antigen in 0.85% NaCl, mixed with N/5 sodium acetate in a 25:1 ratio; weak antigen, diluted as above, gives results similar to a strong standard antigen. Serum pH fluctuated between 7.2 and 8.2. No parallel exists between serum pH and results of the reaction.—*Authors' summary (transl. by A. L. Brody).*

1608. **SILBER, L. A., und S. I. NIKOLSKAJA. Weitere Untersuchungen über die Thermostabilität der Antikörper.** *Zeitschr. Immunitätsforsch.* 64(1/2): 167-172. 1929.—Saturation of immune sera with saccharose increases the thermostability of the antibodies to a remarkable extent. While a number of agglutinating sera (anti-typhoid, anti-paratyphoid, anti-cholera) lost their agglutinative activity entirely after exposure for 1 hr. to 75° C., the same sera when saturated with saccharose showed no appreciable loss of agglutinins after heating for 1 hr. at 80° and 90°. There was, however, a marked reduction of titer after heating for 10 min. at 100°. A similar increase in thermostability of hemolysins (and perhaps antitoxins) under high saccharose concentration could be demonstrated in the respective immune sera. The authors attribute the action of sugar to its capacity to prevent coagulation and denaturation of serum proteins.—*C. W. Jungeblut.*

1609. **SILVEIRA, G. FLEURY da, e J. M. GOMES. A reacção de Kahn na lepra. [Kahn reaction in leprosy.]** *São Paulo Med.* 3(4): (3-7). 1929.—Kahn's reaction lends itself admirably to the diagnosis of syphilis in leprous individuals, giving positive results in a minimum percentage of cases in contrast to the Wassermann reaction which frequently gives positive results when syphilis is not present.

1610. **SMITH, J., and A. M. FRASER. Agglutination reactions in relation to Sonne dysentery.** *Jour. Hyg.* 30(2): 216-220. 1930.—A study of the agglutinin content of the sera of individuals who had had Sonne dysentery showed that in the majority, specific agglutinins were produced. In a series of agglutination tests with sera from 138 normal individuals, 24% gave a positive reaction at dilution 1:50 or greater.—*Authors' summary.*

1611. **SONNENSCHEIN, CURT. Komplementkonservierung durch Kochsalz und Borsäure.** *Zeitschr. Immunitätsforsch. u. Exp. Therap.* 66(3/4): 330-334. 1930.—Determinations of the amount of complement in 631 sera kept for 28 days in borate and NaCl were made. At 4-8° complement was undiminished and at room temp. the titer was only slightly lowered.—*N. W. Larkum.*

1612. **SORDELLI, A., y J. FERRARI. Algunas propiedades de suero antimicrobiano contra B. perfringens. [Properties of B. perfringens anti-serum.]** *Rev. Soc. Argentina Biol.* 6(9/10): 513-518. 1930.—By intravenous injection of *B. perfringens* into horses, a specific serum is obtained having precipitating, agglutinating and complement-fixing properties. By dilution in saline saturated with CO_2 a precipitate is obtained, containing almost all the precipitin and agglutinin but only ½ the complement-fixing antibody. The precipitinogen is not destroyed by boiling, is insoluble in saline and does not fix complement. The edema fluid of infected animals contains the precipitinogen and gives a precipitate with the serum. This may be used as a rapid and simple diagnostic test.—*J. T. Lewis.*

1613. **SORDELLI, A., y J. FERRARI. Los anticuerpos contenidos en el suero anticarbuncloso. [Antibodies in antianthrax serum.]** *Rev. Soc. Argentina Biol.* 6(9/10): 519-524. 1930.—4 types of serum were prepared by subcutaneous or intravenous injection of virulent and avirulent strains of *B. anthracis.* They were fractioned by precipitation with saline saturated with CO_2. Sera obtained by intravenous injection are agglutinating and precipitating, both properties being found in the precipitate. Those obtained by subcutaneous injection do not have these properties. All sera have complement-fixing power, especially when prepared by subcutaneous injection and without relation to virulence of strain. This property is found in the soluble fraction.—*J. T. Lewis.*

1614. **STERN, R. Die Rolle der Dehydration bei der Komplementbindung (Wassermann-Reaktion). [Rôle of dehydration in complement fixation.]** *Zeitschr. Immunitätsforsch. u. Exp. Therap.* 66(3/4): 379-380. 1930.—Polemic note on the work of Reiner.

1615. **STONE, KENNETH. A study of yeasts by the complement-fixation test.** *Lancet* 219(5585): 577-579. 1930.—By using a saline washing of the yeast as antigen the complement-fixation test can be applied in identification of various members of the yeast and sporothrix groups. Specimens of thrush (*Oidium albicans*), obtained from 10 successive cases, gave identical results. By the complement-fixation test, all belong to 1 serological type. Specimens of yeasts obtained from other sources were studied, and are shown to fall into 5 types. The sporothrices of Beurmann and Schenck appear to be identical, and quite distinct from yeasts so far studied. The sporothrices of Gougerot and Jeanselm appear to be identical with black yeasts obtained from other sources.—*Author's conclusions.*

1616. **STRASSMANN, G. Ist die Blutgruppenuntersuchung im Alimentenprozess verwendbar?** *Med. Welt.* 3(9): 321-322. 1929.—The alleged changes in blood groups in diseases are due to errors in technique. The author criticizes the courts for their refusal to render decisions based on blood group examination. This has in the meantime been revoked, and the author has shown that there is no longer justification in doubting the applicability of blood group determination in cases of disputed paternity.—*G. Strassmann (transl. by P. Levine).*

1617. STSCHEDROWITZKY, S. G., A. M. KORABELNIKOW, und E. K. LOPATIN. Die Rolle der Milz in der aktiven Immunität. *Zeitschr. Ges. Exp. Med.* 73(5/6): 625-630. 1930.—Immunizing doses of typhoid vaccine were given to 10 splenectomized rabbits—to 5 immediately after operation, and to 5 at 2, 4 and 6 months afterward. In 4 of the 5 immediately immunized, the agglutination titer rose to 6000-9000 instead of the usual 4000-5000 (seen also in 2 rabbits immunized after laparotomy), remaining at this height for 3-4 mo., and then falling to 2000-2500, the titer shown by the 5 later immunized experimental rabbits. Thyroidectomy in 4 splenectomized rabbits produced a considerable fall in agglutination titer. Castration in 4 splenectomized rabbits scarcely influenced the agglutination titer, but splenectomy in 6 castrated rabbits produced marked rise in agglutination titer. Splenectomy after thyroidectomy was fatal in rabbits. The authors conclude that the spleen has endocrine functions.

1618. SUZUKI, S. Über die Steigerung der Wa-R. beim Kaninchen durch die Injektion der embryonalen Blutkörperchen oder der menschlichen Blutkörperchen von AB-Typus. *Japanese Jour. Dermatol. & Urol.* 30(5): Japanese. 428-442; German summary, 51. 1930.—Rabbit serum which had previously given a negative Wassermann reaction could be rendered distinctly positive by injection of embryonic blood corpuscles, rabbit or human, but not by human adult corpuscles, except of the AB type. This indicates the presence of a common factor in embryonic and adult blood corpuscles of AB type.—*From author's summary (transl.).*

1619. TALLO, F. Influenza della dieta epatica (dieta di Whipple) sui poteri immunitarii dell'organismo. Ricerche sperimentali. [Influence of Whipple's liver diet on the immunity processes.] *Riv. Patol. Sperim.* 5(4/5): 359-370. 1930.—In guinea pigs and rabbits fed with fresh liver added to an ordinary diet, an increase of immunity activity, both natural (phagocytosis, opsonic power) and induced (agglutinins, bacteriolysin), develops if the animals are vaccinated with typhoid bacilli. The immunity activity is increased, after an initial diminution, in animals repeatedly bled. The presence in the liver of a substance affecting immunity through its action on the hemopoietic system is suggested.—*M. Comel.*

1620. TAYLOR, K. P. A. Apparent cure of purpura hemorrhagica by bothropic antivenin. *Bull. Antivenin Inst. America* 3(2): 42-43. 1929.—The efficacy of bothropic antivenin *Bothrops atrox* was demonstrated in stopping hemorrhages of a patient with purpura to whom other treatments such as normal horse serum, $CaCl_2$ and ergotin had been unsuccessfully applied.—*A. do Amaral.*

1621. TERRELL, EDWARD E. Changes in humoral immunity occurring during the early stages of experimental pneumococcus infection. *Proc. Soc. Exp. Biol. & Med.* 27(5): 353-354. 1930.

1622. THEILHABER, A. Der Einfluss der Einverleibung lebender tierischer Organteile auf die Körperkonstitution und Krankheitsdisposition. *Arch. Frauenk.* 16(4): 295-307. 1931.—Implantation of endocrine organs into 131 cancerous patients brought improvement: the tumor reduced in size; hemorrhages, discharges and pain often regressed; metastases were reduced and sometimes they and the primary tumor disappeared. The glands were taken from young pigs treated a few days previously by injection of an emulsion of spleen, liver, thyroid, and thymus from a freshly killed rabbit. The spleen, thymus, thyroid, some of the liver, and a piece of the femur were implanted subcutaneously into the thigh or abdomen. The febrile reaction hastened healing. In an unstated number of tuberculous patients, also in 34 with diseases of the central nervous system, 4 with arthritis deformans, 1 with severe Bürger's disease, 4 of 5 with inoperable sarcoma, 1 with Hodgkin's disease, and 1 with severe pyosalpinx, improvement occurred after implantation. These results, the author believes, indicate that implantation increases the local, general active, passive, specific, and non-specific immunity.

1623. THOMSEN, O. Der Wert der Blutgruppenbestimmung in Vaterschaftssachen, wo die Gruppe der Mutter unbekannt ist. *Zeitschr. Rassenphysiol.* 3(3/4): 103-107. 1931.—The author considers the incidence of the 3 possible outcomes of serological paternity diagnosis in cases where the blood group of the mother is unknown, viz., (1) the man could be the father of the child, no matter what the group of the mother, (2) the man could not be the father of the child under any circumstances, and (3) the question could not be decided without a knowledge of the blood group of the mother. On the basis of the Landsteiner groups O, A, B, and AB, the following incidence is obtained: 62.50%, 2.58% and 34.92%, respectively, where 2.58% represents those cases in which an O father could not give rise to an AB child, and an AB father could not give rise to an O child.—*P. Levine.*

1624. TIEGS, E. Über Platanenhaare. (I. Mitteilung). Kleine Mitteil. *Mitglieder Ver. Wasser-, Boden-, u. Lufthygiene* 6(7/10): 193-198. 3 pl., 2 fig. 1930.—The author found that there are especially sensitive individuals who are injured by the branching hairs of plane tree leaves. This injury exhibits its manifestations partially in the respiratory apparatus and partially in the eyes.—*Author's conclusions (transl. by W. W. Herrmann).*

1625. TRAUM, E., und E. WITEBSKY. Zur Bedeutung von Untergruppen bei der Bluttransfusion. *Chirurg.* 1(20): 930-932. 1929.—The authors describe a blood of group AB, the serum of which acts on some cells of group A. They believe that the occurrence of atypical agglutinins of this sort may explain a number of post transfusion reactions.—*P. Levine.*

1626. VAGHI, LORENZO. Sul fenomeno dell'anacoresi. VII. Riduzione della mortalità nell'afta sperimentale della cavia mediante l'anacoresi. [Studies on anachoresis. VII. Mortality reduction by anachoresis in the guinea pigs experimentally infected by foot-and-mouth disease.] *Biochim. e Terapia Sperim.* 17(7): 295-309. 1930.—In experimental foot-and-mouth disease in guinea pigs anachoresis due to subcutaneous injections of BCG exerts a favorable action on the infective process. Its generalisation is not prevented; but the mortality shows a noticeable decrease (33% fatal cases) in treated as compared with the non-treated animals (73% fatal cases).—*M. Comel.*

1627. VERGE, JEAN. Une nouvelle méthode de tuberculination: l'intradermo-tuberculination. Seconde. *Rev. Gén. Méd. Vét.* 40(469): 1-6. 1931.—The technique of the test is described and results of different methods are compared. The intradermal test is convenient, and it is concluded to be the best method for routine practice.—*J. Verge (transl. by L. C. Havens).*

1628. VIOLA, DOMENICO. I gruppi sanguigni come fattore etno-antropologico. Contributo alla distribuizione regionale dei gruppi sanguigni in Italia. [Blood groups as ethno-anthropological factors. Regional distribution of blood groups in Italy.] *Boll. Soc. Med.-Chir. Pavia* 42(5): 897-921. 1928.—Examination of the blood groups of 1000 Italians from various regions showed great differences in racial index, which begins with 3.6 in northern Italy and decreases to 1.6 in Sicily. Dividing Italy into 3 parts, the index corresponds to 3.6 for northern Italy, 3.6 for central Italy and 3 for southern Italy. There is an evident analogy between blood group index and distribution of races in Italy. While the Eurafrican type is more concentrated in the South and in the islands, northern Italy belongs to the Eurasian type which reaches down partly to central Italy. The blood group being the most complex constitutional factor of the individual, it is to be considered of the greatest importance for study of anthropological differences in man.—*M. Goldstein.*

1629. WAALER, GEORG H. M. To nye blodtyper. Referat og egne undersøkelser. [Two new types of blood.] *Norsk Mag. Laegevidensk* 9(5): 511-518. 1930.—The studies of Thomsen and co-workers on the subgroups of group A are described. The author examined 28 families in which one or both parents belonged to

group A or AB; he believes that his results lend support to Thomsen's view on the heredity of the blood groups. —*P. Levine.*

1630. **WALL, SVEN.** Communication respecting some experiments which support the theory that, under certain circumstances, a subcutaneous injection of killed tubercle bacilli can increase the power of resistance of the animals treated to a subsequent infection with tubercle bacilli. *Acta Pathol. et Microbiol. Scandinavica Suppl.* 5: 24-29. 1930.

1631. **WEIL, A. J.** Zur Kenntnis der Antigenstruktur von Organlipoiden. [The antigen structure of the organ lipoids.] *Zeitschr. Immunitätsforsch.* 58(1/2): 172-180. 1928.

1632. **WEIL, ARTHUR, and DANIEL M. LIPSCHUTZ.** The standardization of the hemolytic index. *Proc. Soc. Exp. Biol. & Med.* 27(9): 1055-1056. 1930.—Preliminary paper.

1633. **WEINERT, HANS.** Blutgruppenuntersuchungen an Menschenaffen. [Investigation of blood groups in anthropoid apes.] *Kosmos [Stuttgart]* 26(11): 375-378. 2 fig. 1929.—The author briefly reviews the work of Landsteiner and Miller who showed that the human blood groups are present also in the cells of chimpanzees, orang-outangs and gibbons, and reports on a few observations of his own.—*P. Levine.*

1634. **WELIKANOW, I. M., und E. N. TOLSTUCHINA.** Zur Erforschung der Immunität gegen die Mikroben des malignen Oedems. *Zentralbl. Bakt. I. Abt. Orig.* 120 (1/2): 78-83. 1931.—The authors cultivated vibrion septique under conditions preserving high virulence and, by addition of formalin, transformed the culture into a harmless vaccine with good antigenic properties. Immunization of guinea pigs or rabbits with this vaccine produced an active immunity against 2-5 lethal doses of a 1-3-day culture. Serum of these animals at 1: 10 dilution neutralized in vitro 1-10 lethal doses of culture. Immunization of 2 horses with the formalinized vaccine produced a marked immunizing reaction. Serum of such horses at 1: 1000 dilution neutralized 1-10 lethal doses of a 1-3-day culture of vibrion septique; this serum possesses marked therapeutic properties.—*Authors' summary (transl.).*

1635. **WELLISCH, SIEGMUND.** Das Blutgruppenproblem vor Gericht. *Zeitschr. Rassenphysiol.* 2(4): 172-178. 1930.—The author, accepting the Bernstein theory, considers the 4 Landsteiner blood groups from a genetic point of view and thus has 6 types, OO, AO, AA, BO, BB, and AB. Should it be possible to distinguish serologically homozygous and heterozygous individuals in groups A and B, the scope of the forensic application of the blood groups would be considerably enhanced.—*P. Levine.*

1636. **WENT, STEPHEN.** Molecular movement, viscosity and agglutination. *Jour. Immunol.* 19(4): 347-356. 1930.—Brownian motion ceases with sufficient increase in viscosity of dispersing medium. Spontaneous flocculation may occur. The absolute temp. of the medium and the dimension of the bacterial surface are influencing factors. High viscosity may hinder specific agglutination by preventing adsorption of immune bodies. —*J. H. Black.*

1637. **WESTENRIJK, N.** Eine Methode zur Phagozytosebestimmung der Tuberkelbazillen mit den Phagozyten des tuberkulösen Menschen in vitro. *Zeitschr. Tuberk.* 57(6): 393-397. 1930.—The method described was tried on laboratory dogs and on 10 human patients. The author finds that the more severe the disease, the smaller the % of active phagocytes, provided strains of equal toxicity are used, for the more toxic bacilli inhibit phagocytosis.

1638. **WHITE, P. BRUCE.** Notes on organisms serologically related to S. enteriditis Gärtner. I. The Dublin and Tokyo types of Salmonella. *Jour. Hyg.* 29(4): 443-445. 1930.—The somatic antigen of the Dublin type is identical with that of *S. enteriditis;* when enteriditis serum is saturated with the Dublin type, or Dublin serum with the enteriditis type, there remains in each case a definite residue of flagellar agglutinins for homologous organisms. The Tokyo type is a typical diphasic form; its somatic antigens, as well as the flagellar antigens of its specific phase, are identical with those of enteriditis. The non-specific phase, while reacting little or not at all to flagellar agglutinins of Gärtner sera, is vigorously clumped by the non-specific phase antisera of paratyphosus B, aertycke Newport, and other diphasic types. —*Hester A. Austin.*

1639. **WIECHMANN, ERNST, und FRITZ KOCH.** Hat "Bayer 205" einen Einfluss auf den anaphylaktischen Shock? *Arch. Exp. Path. u. Pharmakol.* 132(1/2): 118-121. 1928.—Guinea pigs sensitized with horse serum, were reinjected with serum mixed with "Bayer 205" or received "Bayer 205" shortly before or after reinjection of serum. No effect on the resulting anaphylactic shock was observed.—*G. H. Robinson.*

1640. **WILLIAMS, A. WINKELRIED.** Leprosy: treatment by means of a special vaccine. *Arch. Dermatol. & Syphilol.* 22(1): 109-114. 1930.—Reports of 2 cases and brief notes on 3 others in which an autogenous vaccine appeared to produce recovery or improvement.

1641. **WORINGER, PIERRE.** Die Wirkung des Sonnenlichtes auf die immunisatorische Funktion der Haut. *Strahlentherapie* 39(3): 493-499. 1931.—Clinical experiments were made on children in the incubation period of chickenpox and measles, and on infants bilaterally vaccinated, one half of the body being exposed to ultraviolet, the other half covered with black cloth. In those with chickenpox and measles the exanthema appeared earlier and was more florid on the irradiated side (in measles the action was not observed when the skin was darkly pigmented by daily exposure to sun). Irradiation also accelerated and intensified the vaccination reaction. In no case was erythema produced. Light thus accelerated and intensified the specific defense reaction.

1642. **YAMAMOTO, HIROYUKI.** Immunologische Untersuchungen der organspezifischen und zytotoxischen Eigenschaften des Antiserums der Leukozyten des Kaninchens. *Japanese Jour. Exp. Med.* 15(3/4): 324-332. 1930.—Polynuclear leucocyte antiserum was prepared from rabbits by Spät's method; mononuclear leucocyte antiserum, by Besredka's method; and Eosinophile leucocyte antiserum, by the author's method. Antisera to muscle, liver, kidney, spleen and intestine were prepared from rabbits, which were bled from the carotid artery and before death were injected with physiologic saline. The organs were then washed free of blood. The precipitin reaction was used. Results showed that the leucocytes of rabbits possess strict specificity, and every type of leucocyte can be identified by the method. Polynuclear leucotoxin seems to possess a characteristic damaging influence on polynuclear leucocytes.—*P. G. Heineman.*

1643. **YOSHIDA, S.** Immunitätsforschung der Spirochaetenkrankheiten. I. Lokale Immunität bei der Syphilis. II. III. Ueber die lokale passive Immunität der Rattenbisskrankheit beim Kaninchen. IV. Über die Superinfektion bei der Rattenbisskrankheit der Kaninchen. [In Japanese, with German summaries.] *Acta Dermatol.* 16(2): 169-193. 7 fig.; (3): 255-272. 5 fig.; (4): 343-358. 3 fig.; (6): 540-551. 1930.—I. Local immunity which becomes established before general, is of primary importance in the study of experimental syphilis. At various periods after inoculation of the right scrotal skin with syphilis, and appearance of local lesions, rabbits were treated with salvarsan. About 1 month after treatment they were reinoculated with the same amount of syphilitic virus and by the same method, on the right and left scrotum. In rabbits treated a long time after the 1st inoculation, a high-grade immunity against syphilis had been established and no reinfection occurred; also, the inflammatory reaction was much slighter on the right scrotum, where the 1st inoculation had produced a chancre, than on the left side, which had no local lesion. In rabbits treated relatively early after the 1st inoculation, reinfection took place, because the immunity produced was yet weak, but in this case

also the chancre was smaller on the right side than on the left and the incubation time was longer. II. Serum from a rabbit that had had syphilis was used to immunize a healthy rabbit, while a control rabbit was injected with serum from a healthy rabbit. Both were then inoculated with syphilis. The inflammation and size of primary lesion proved smaller and the incubation period longer in the immunized rabbit. III. Serum from a rabbit which had had rat-bite fever was subcutaneously injected on 1 side of the back of a healthy rabbit; serum from a normal rabbit, on the other side. Rat-bite spirochaetes were then introduced into both inoculation sites. The author reports a certain local protective action. IV. Method of inoculation has no great effect on production of immunity, but size of dose is important: a large dose produces early immunity, a small dose late. Immunity against rat-bite fever in rabbits begins to form as early as 1 wk. after inoculation, and becomes high grade in 17-18 days, after which the rabbit cannot be superinfected.—*From author's summaries (transl.).*

1644. **ZINGALE, MICHELE.** Sul meccanismo della malarioterapia nella paralisi progressiva. [Mechanism of malaria therapy in general paralysis.] *Gior. Ital. Derm. e Sifil.* 71(5): 1733-1741. 1930.—The author reviews and rejects the various other theories offered to explain the mechanism of malaria therapy in general paralysis, and offers the theory that malaria furnishes a non-specific stimulus to histogenic immune processes in specifically injured nerve cells.

LOWER ANIMALS

1645. **BERGEON, P. (Préface de E. LECONTE.)** La peste bovine au Tonkin et la vaccination antipestique. État actuel de la question. 35p. *Service Zootech. et Epizooties Tonkin* [Unnumbered series]. 1930.—Bovine plague has caused the loss of thousands of valuable cattle, buffaloes and other animals in Tonkin and Indo-China during past yrs. Efforts to check its spread by segregation, slaughter of infected animals, and passive immunization with blood of animals recovering from the disease have been unsuccessful. The method of protection known as "sero-infection," based on injection of a mixture of immune blood and blood containing the virus, has not been an effective control method, because many animals were killed by the treatment and new foci were established. Since 1928, the veterinary service of Tonkin, working in conjunction with the Pasteur Institute of Nhatrang, has applied the vaccination method of Kakisaki, Nakanischi and Ozumi. Results have been extraordinarily beneficial, vaccinated animals resisting artificial and natural infection. Well controlled tests showed that the method produces an immunity lasting a yr. and that by it the spread of the disease can be checked. The vaccine is made from a pulp of the liver, spleen, tonsils, thymus, thyroid, and lungs of an infected animal, which is killed on the 8th day of the disease, and these organs removed. During the process of hashing and grinding, the organs are kept in water containing 5% phenol. The syrupy liquid obtained after straining the pulp is treated with 8% formalin, held at 25-30°C. for 24 hrs. and then in the ice-box. The virus, as well as bacteria, is killed; the vaccine is, therefore, a virus killed by phenol and formalin. 1 injection is given for immunization. Details on method of preparation, mode of administration and practical suggestions on procedures for control of bovine plague are given.—*S. Bayne-Jones.*

1646. **BIELY, J., C. E. SAWYER, C. M. HAMILTON, W. T. JOHNSON, and E. M. DICKINSON.** Accuracy of three cooperating laboratories in detecting pullorum disease by the agglutination test. *Jour. Amer. Vet. Med. Assoc.* 32(1): 19-36. 1 pl., 1 fig. 1931.—15 negative (−) and 15 positive (+) reacting fowls were procured at random by each laboratory and all survivers were bled 4 times at 4-week intervals, for testing. 3 blood samples were drawn from each at every bleeding and tested at 3 laboratories (British Columbia, Washington, Oregon), each applying its own technique. A total of 1041 blood samples was tested and a diagnosis made for each: 531 +, 8 suspicious and 502 −, or a disagreement of 0.77% of the 1041 diagnoses. The disagreements were from − or + to suspicious and not from − to +, or the reverse, 1 fowl changed from − to +, but none changed from + to −. Postmortems of the 46 + reacting fowls definitely established *S. pullora* infection in 44 (95.65%), and characteristic lesions in the other 2 indicated a probable 100% *S. pullora* infection. Postmortems of the 44 fowls never giving a + reaction were 100% −, as determined bacteriologically and by absence of *S. pullora* lesions. All 3 laboratories were in absolute accord in the 342 test diagnoses of the 15 + and 15 − reacting fowls of laboratory 3, and postmortems established the + fowls as infected and the − fowls as not infected, as determined by gross and bacteriological examinations.—*Authors' summary.*

1647. **EDGINGTON, B. H., and ALVIN BROERMAN.** A comparison of the intradermal and agglutination tests for pullorum disease, based on demonstrating the infection in the hatch from reactors. *Jour. Amer. Vet. Med. Assoc.* 31(2): 219-224. 1931.—Hens in the group reacting to the agglutination test but not to the intradermal test, transmitted *Salmonella pullorum* infection in each of 10 hatches. If the flock had been divided on the basis of the intradermal test only, these hens would have remained in the negative group and would have been a source of disseminating pullorum disease. The hens reacting to the intradermal test but not to the agglutination test failed to transmit infection to chicks during the hatching period.—*From authors' conclusions.*

1648. **GWATKIN, RONALD.** Brucella abortus agglutinins in the blood of sows slaughtered in Toronto. *Cornell Vet.* 21(1): 77-80. 1931.—Of the 267 sera examined with both antigens, 45 showed agglutination at 1 or more dilutions. 3 samples gave complete agglutination at 1:25 dilution in both antigens. 2 were negative in bovine and complete at 1:25 in the porcine antigen. 2 samples gave complete agglutination at 1:25 in the former, and partial in the latter, antigen. 17 samples showed a partial reaction at 1:25 dilution with both antigens. 12 were partial at 1:25 with bovine antigen and negative with porcine. 1 was negative in bovine and partial at 1:25 in porcine antigen. Antigen prepared from the bovine strain appeared in general to be more readily agglutinable than the porcine strain used. In testing cattle with antigen of this density, agglutination at 1:25 must be considered as due to normal agglutinins. At times, such a reaction may indicate an infected animal, but if taken into consideration in routine work many animals are recorded as suspicious, to be later classified as negative. If the same basis is accepted for swine blood, the majority of these reactions may be ruled out, leaving 1 partial and 2 complete reactions at 1:100 and 4 complete reactions at 1:50.—*Author's conclusions.*

1649. **JOHNSON, E. P.** Results of experiments with the use of pigeon-pox virus as cutaneous vaccine against fowl-pox. *Jour. Amer. Vet. Med. Assoc.* 32(1): 81-86. 2 fig. 1931.—Vaccine prepared from scabs of infected pigeons was applied to the breasts of 74 pullets after removing several feathers; 8-10 days later, 72 birds had perfect "takes" as did the remaining 2 when revaccinated. Doyle's method proved unsuccessful. No ill effects on the birds resulted, nor was any decrease in egg-production noted, following vaccination.

1650. **KALOJANOFF, A.** Интрадермалната туберкулинна реакция и нейното приложение като методъ за диагнозирване въ борбата съ туберкулозата по домашнитѣ животни въ България. [The intradermal tuberculin test and its application in the campaign against bovine tuberculosis in Bulgaria.] Годишникъ на Софийския Университетъ, Ветеринарномедицински факултетъ (*Jahresber. Univ. Sofia, Vet. Med. Fakult.*) 6: 283-314. 1930.—Examination of 1,902 cattle and buffaloes gave the following results: Cattle which were + by the subcutaneous test, were 80% +,

12-15% doubtful and 5-8% — by the intradermal test. Those — by the subcutaneous, were 3% +, 3.4% doubtful, and 93-95% — by the intradermal test. Those + by the intradermal, were 75% +, 10-15% doubtful, and 10-15% — by the subcutaneous test. Those — by the intradermal were 3% +, 4-5% doubtful, and 92-93% — by the subcutaneous test. Postmortems showed the subcutaneous test to be about 10% more reliable than the intradermal test.—*A. Kalojanoff (transl. by A. L. Brody).*

1651. MIESSNER, H., und R. BERGE. Schnellagglutinatonsmethoden zur Erkennung der Pulloruminfektion beim Huhn. *Deutsche Tierärztl. Wochenschr.* 38(26): 401-406. 4 fig. 1930.—The fresh blood method recommended requires 1 drop of blood from comb or cockle, placed on a clean slide and mixed with 1 drop of antigen by the blood-removing instrument. Antigen consists of a thick suspension of a strongly agglutinating strain of *Bact. pullorum* in saline. When the agglutination is positive a marked flocculation occurs in a few min. The method can be carried out on the spot, thus making possible immediate separation of infected from uninfected birds. The method should be used by qualified veterinarians only and laboratories should issue the antigens only to them.—*H. Miessner (transl. by W. E. Thrun).*

1652. MITCHELL, CHAS. A., and F. A. HUMPHREYS. Studies in Brucella melitensis (abortus) infection of cattle. *Cornell Vet.* 21(1): 57-67. 1931.—In a positive-reacting herd of 16 animals, 12 were proved to excrete *Br. melitensis (abortus)* from 1 or more quarters of their udders—2 animals had 1, 3 had 2, 5 had 3, and 2 had 4 quarters infected. In each case milk from the infected udder reacted to agglutination or to complement fixation tests,—usually to both. In each case where agglutinins and complement-fixing substances were absent, guinea pig inoculation was negative. In several instances the milk reacted to both tests but organisms were not demonstrated. Guinea pigs having in their blood on the first bleeding only 1 of the 2 antibodies, with 1 exception, presented complement-fixing substances first, agglutinins appearing later.—*From authors' summary.*

1653. MORCOS, Z. Avian pox immunization. *Veterinary Record* 11(17): 463-465. 6 fig. 1931.—1/500 formalized pigeon virus emulsion equivalent in opacity to 1/1000 $BaSO_4$ solution, is protective to both fowls and pigeons. The blood of an infected bird is infective. The bird pox virus is not pathogenic to guinea pigs or white rats on intradermal inoculation; sparrows fed on the virus show no apparent lesions. Doves contract pigeon pox and the dove virus does not protect pigeons, but is infective.—*Author's summary.*

1654. [OBUKHOVSKIĬ, B. I., and A. N. PASHKOVSKIĬ.] ОБУХОВСКИЙ, Б. И., и А. Н. ПАШКОВСКИЙ. Вакцинация телят против туберкулеза по методу Calmett'a-Guérin'a. **[Vaccination of calves with BCG.]** [With French summary.] Вопросы Туберкулеза [*Voprosy Tuberkuleza*] 7(7): 773-778. 1929.—BCG vaccine injected subcutaneously provoked brief hyperthermia, and an infiltration at site of injection, which soon healed; animals remained well. Emulsion from these infiltrates was injected into guinea pigs, but caused no tubercular infection. 7-8½ mo. after vaccination, 13 vaccinated calves and 4 controls were infected intravenously. Controls died; vaccinated calves remained alive, but on autopsy showed tuberculous lesions; emulsion from these lesions killed guinea pigs. Thus, vaccination prevented death, but not tuberculosis. A 2nd group of experiments aimed to determine the appearance of immunity and its duration. Calves were infected 3 months after vaccination; tuberculous processes in vaccinated calves were less grave than in controls. The 3rd group of experiments was intended to establish the immunity of vaccinated calves against infection by contact; apparently contact conditions were insufficient, since neither controls nor vaccinated calves became infected. From the last group, 1 control and 4 vaccinated calves were infected intravenously with a double dose of virus (10 mg.). The control and 1 vaccinated animal died. In all, of 12 controls, 5 died; of 22 vaccinated, 1.—*B. Van Rosen.*

1655. SUNDBERG, RAGNAR. Virulensmätningar av 4 olika abortbacill-stammar med användning av marsvinsympning och upprepade bestämningar av de ympade marsvinens agglutininhalt. [Measurements of the virulence of 4 strains of abortus bacilli used in inoculating guinea pigs, and repeated determinations of the agglutinin percentages in the latter.] [With English summary.] *Skandinavisk Vet.-Tidskr.* 21(4): 97-102. 1931.—When injecting equal quantities of infective material of the same antigen strength into guinea pigs, it is possible, guided by regular determinations of the agglutination % in the treated animals, to obtain an idea of the comparative virulence of the strains, the rule found being that the strain regularly giving highest agglutination values should be considered most virulent.—*Author's summary.*

ANIMAL IMMUNOLOGY

PARASITOLOGICAL

W. H. TALIAFERRO, *Editor*

(See also in this issue Entries 1365, 1498, 1516, 1541, 1569, 1676, 1679, 1723, 1735)

1656. GAC, P. le. La réaction de Targowla dans la trypanosomiase humaine. *Bull. Soc. Path. Exotique* 23 (5): 530-532. 1930.—The etiologic and clinical analogies between general paralysis and the 2nd period of sleeping-sickness led the author to try Targowla's reaction in 9 cases of human trypanosomiasis, 4 of the early 2nd period, 3 of the late 2nd period, and 2 of the 3rd. All cases of the 3rd and of the late 2nd periods and 2 cases of the early 2nd gave strongly positive reactions; 1 case was negative and 1 weakly positive. He regards the results as prognostic, a negative result being favorable, while a strongly positive reaction remaining unchanged after treatment indicates a fatal termination.

1657. [IAKIMOV, V. L.] ЯКИМОВ, В. Л. К вопросу об иммунитете при пироплазмозах крупного рогатого скота. **[Immunity in piroplasmosis of large horned cattle.]** Русский Журнал Тропической Медицины, Медицинской и Ветеринарной Паразитологии [*Russ. Jour. Trop. Med., Med. & Vet. Parasitol.*] 7(4): 289-299. 1929.—The author conducted numerous immunization tests with cows, against *Babesiella bovis*. Past infection does not prevent reinfection, nor could any hereditary immunity be observed in calves born of mothers once affected. There is a possibility of natural immunity, for of 100 cows brought from regions free of the disease and placed in surroundings where it was endemic, 25 remained free from infection. Immunization with trypan blue plus virulent blood, as well as with ichthargan and with arrhenal, creates an immunity lasting not over 1 yr. Immunization with trypan blue alone creates no immunity, but may lessen the intensity of infection. On the whole, the author thinks that no permanent and definite immunity against piroplasmosis can be achieved.—*B. Van Rosen.*

1658. LOTZE, HARALD. Die künstliche Proteosomainfektion der Vögel. Ein Beitrag zur Frage der Immunität und Immunisierung bei Vogelmalaria. II. *Zentralbl. Bakt. I. Abt. Orig.* 120(1/2): 107-113. 1931.—From experiments on birds the author concludes that passive immunization methods confer no immunity in malaria, but that active immunization provides a certain degree of immunity. Especially favorable results were obtained by immunization with plasmodia of reduced virulence, which, though they produced only a local infection, had

as powerful an immunizing action as normal parasites. These studies indicate that *Proteosoma praecox* is able to produce toxins and that infection with avian malaria may take place through food.—*Author's summary (transl.).*

1659. RADOSAVLJEVIC, A. Versuche zum Nachweis von Antikörpern bei Malaria. *Arch. Schiffs- u. Tropen-Hyg.* 34(12): 629-643. 1930.—The antigen used for complement fixation was an alcoholic extract of dried blood containing the 3 types of human parasites; this was controlled with a similar extract of uninfected blood. In complement fixation the author made 354 tests on 102 (60 samples of serum were anticomplementary) individuals. Working with patients having injection malaria, he concludes that specific complement-fixing antibodies occur in malaria, that they cannot be demonstrated before the 5th rigor, that they are still present 10-30 days after spontaneous cessation of fever, and that successful treatment with quinine, plasmochin and stovarsal is followed by disappearance of antibodies, although no more rapidly than after spontaneous cure. As a result of serum treatment of 26 infected persons, with serum taken from cases having undergone spontaneous cure, he believes that such serum is antitoxic and contains an antiparoxysmal property. Experiments are cited indicating that under certain conditions the serum from spontaneously cured cases can prevent infection when mixed with virulent blood; from this it is concluded that antiparasitic properties arise in the serum during malaria.—*W. H. Taliaferro.*

1660. REGENDANZ, P. Ueber das Fehlen trypanozider Stoffe im Liquor cerebrospinalis des Menschen. *Zentralbl. Bakt. I. Abt. Orig.* 120(1/2): 89-93. 1931.—Simultaneous injection into 28 mice of trypanosome containing blood and cerebrospinal fluid gave no evidence of the presence in the latter of trypanocidal antibodies. While human serum in doses of 0.1-0.2 cc. has been shown to have a distinct trypanocidal effect on mice, 8 mice infected with *Trypanosoma brucei* and *T. rhodesiense* were not affected by 20-100 times as much cerebrospinal fluid. The author explains the absence of trypanocidal antibodies in the cerebrospinal fluid by the well-known fact that the blood-cerebrospinal fluid barrier is permeable to blood but not to the fluid.

1661. SICÉ, A. Recherches sur le pouvoir floculant du sérum des trypanosomés. (Note complémentaire.) [The flocculating power of serum from trypanosomiasis patients.] *Bull. Soc. Path. Exotique* 23(5): 459-460. 1930.

1662. ZDRODOWSKI, P., et B. WOSKRESSENSKI. Essai du sérodiagnostic et de l'analyse sérologique de la leishmaniose viscérale humaine et canine au moyen de la réaction de la fixation de l'alexine. *Bull. Soc. Path. Exotique* 23(10): 1028-1043. 1930.—The authors regularly obtained complement fixation in presence of corresponding antigen in sera from human and canine leishmaniases, with a special method described. Human kala-azar sera originating in Azerbaidjan regularly gave a strongly positive reaction with *Leishmania donovani* and a negative or faintly positive reaction with *L. tropica*. Serum from Azerbaidjan dogs affected with visceral leishmaniasis, however, gave a very positive reaction with *L. tropica* and either a distinctly positive or a completely negative reaction with *L. donovani*. These cross reactions thus indicate that here, at least, *L. donovani* and *L. canis* are distinct species or varieties. The authors remark, however, that the pathologic and the serologic properties of parasites are not always parallel.

1663. ZDRODOWSKI, P. Sur la sérologie comparée du groupe de Leishmanies d'origine humaine et canine. *Bull. Soc. Path. Exotique* 24(1): 37-41. 1931.—The authors had previously shown that human kala-azar antisera differentiate clearly between *Leishmania donovani* and *L. tropica*. Hence it appeared that the receptor apparatus of *L. donovani* and *L. tropica* are clearly differentiated and "monovalent." Dogs infected with *Leishmania* gave 2 different types of reaction: 1 group gave complement fixation with *L. tropica* and was therefore regarded as infected with a species at least related. A 2nd group gave a polyvalent serum, reacting positively with both *L. donovani* and *L. tropica;* this infection was ascribed to *L. canis*, strain CI. No dogs, however, have as yet given a specific reaction with *L. donovani* alone. The authors report obtaining from a dog with visceral leishmaniasis, a serum which fixed complement with *L. donovani* and *L. canis* CI, but not with *L. tropica*—a reaction identical with that of kala-azar sera. They conclude that *L. donovani* and *L. tropica* represent 2 distinct or standard types of human leishmanias, differentiated by their serologic receptor apparatus; but that the name *L. canis* embraces 3 serologic types, 1 entirely identical with that of *L. donovani* (type D), 1 analogous with that of *L. tropica* (type T), and a polyvalent type (DT) giving positive reactions with both *L. donovani* and *L. tropica*. They incline to the belief that the canine parasites, type D and type T, are to be identified with their respective prototypes, *L. donovani* and *L. tropica;* but that type DT (which they have carried through successive transfer cultures for 1 yr. and believe to be an unmixed strain) is entitled to be regarded as *L. canis* sui generis.

1664. ZIMMERMANN, GERHART. Ueber die trypanozide Wirkung des menschlichen Serums im Tierversuch und in vitro. *Zentralbl. Bakt. I. Abt. Orig.* 120 (7/8): 422-440. 1931.—The direct trypanocidal action of human serum, demonstrated in vitro by Yorke, Adams and Murgatroyd, was confirmed in 5 experiments. The hypothesis of Rosenthal and his collaborators, based on experiments with mice previously given several doses of human serum, of the indirect action of human serum on trypanosomes, was refuted by new animal experiments in which trypanosome infection was inhibited immediately after administration of human serum, but later became active, showing that the trypanocidal action was exerted by human serum and not by antibodies formed in response to the stimulus of the serum. The trypanocidal action of serum from cases of jaundice and hepatic disease was found not to be entirely destroyed, but merely reduced. This is evidence against Yorke's theory of the possibility of human infection with trypanosomes ordinarily non-pathogenic for man, through destruction of the trypanocidal power of the blood by these diseases.

Internal Med.* 41(4): 574-578. 1 fig. 1928.—Locke's-egg-blood and other media were successful. In L.-E.-albumen, with 48-hr. transplants, *C. dissimilis* survived indefinitely, while *Endamoeba dysenteriae* soon died out. Under certain conditions *C. dissimilis* encysted in L. E. B. culture while *E. dysenteriae* did not. *C. dissimilis* cysts from cultures and stools excysted in

culture. Cultural forms show the structure described for the species.—*C. Lucas.*

1667. **BEVAN, LL. E. W., and D. A. LAWRENCE. A note on the internal parasites of sheep in S. Rhodesia.** *Vet. Jour.* 86(6): 199-200. 1930.—List with notes.

1668. **BREINDL, V. Über einen interessanten Flagellatenbefund im Blute der Malariakranken.** *Centralbl. Bakt. 1 Abt. Orig.* 111(6/8): 406-408. 4 fig. 1929.—With carefully checked Giemsa stain and distilled water, a small flagellate was found in the blood of troops returning from the tropics and suffering from malaria. The organism resembles *Bodo* morphologically, and measures 5.9μ × 3.4μ. There are 2 flagella, the anterior 10-12μ, the posterior 22-36μ in length.—*D. Koch.*

1669. **CALDWELL, FRED C., ELFREDA L. CALDWELL, and GORDON E. DAVIS. Some aspects of the epidemiology of infestation with Trichuris and Ascaris as revealed in a study at the hospitals for the insane and the home for mentally defective children in the State of Alabama.** *Amer. Jour. Hyg.* 11(3): 619-651. 5 fig. 1930.—A survey in 1927 demonstrated that in these institutions, as compared with the state as a whole, infestation with *Trichuris* was startlingly high, infestation with *Ascaris* far exceeded the normal, and infestation with hookworm exceeded expectations from statistical analysis. Correlation of infestations with varying lengths of residence indicated that the vast majority of patients became infested with *Trichuris* and *Ascaris* after admission to the hospital, and that infestations with hookworm increased unless modified by treatment. Infestations increased also with succeeding periods of residence. Infestations with *Trichuris* and *Ascaris* were essentially of "dooryard" origin from pollution of the soil. Spread is dependent on the character and habits of the patient and his opportunity to come in contact with the polluted soil, which in turn is dependent on his activity and the size of the yard.—*From authors' summary.*

1670. **CELLI, ANGELO. Die Malaria in ihrer Bedeutung für die Geschichte Roms und der römischen Campagna. Eine Kulturhistorische Studie.** viii+118p., 1 map. Georg Thieme: Leipzig, 1929.—This is an abridged German edition of a much more extensive study in Italian published posthumously in 1925 (*Mem. R. Accad. Lincei Cl. Sci. Fis., Ser. 6* 1(3): 73-467). It aims to show that there has been throughout the past 25 centuries in the Roman Campagna a rhythmic periodicity in the increase and decline of malaria, entirely due to natural causes. Except for the 18th and 19th centuries, the author's arguments are entirely taken from historical sources. Periods when malaria was on the decrease coincided with agricultural prosperity and a dense population in the Campagna. The history of the Campagna was independent from that of the city of Rome, where malaria was always very mild. There appear to have been 4 main waves of severe malaria, each lasting 2-4 centuries and separated by shorter or longer periods when the disease was mild, although it never died out completely. During the earliest, or pre-Roman period, malaria was apparently mild. In order to collect drinking water, the Etrusci had carried out extensive draining in Latium, which may have contributed to sanitate the country. It is impossible to decide when and how malaria was first introduced into the country. After the founding of Rome and during the first centuries of the Roman Republic, malaria became very severe and the population of the Campagna dwindled away. The worship of a special fever goddess, Dea febris, can be traced to the earliest times and persisted in Rome until 300 A. D. With the rise of Imperial Rome malaria was on the decline and the Campagna became once more densely populated. In late Imperial times, however (5th to 7th centuries A. D.), it flared up again, but in early Mediaeval times it decreased once more, especially during the 8th century. A particularly severe and protracted malarial period covered the later Middle Ages (10th-13th centuries), when the unhealthful condition of the Campagna became notorious and many prominent people died of fever. Malaria became again attenuated during the Renaissance (14th-16th centuries), but during the Modern Period it blazed out anew. The word "malaria" first entered the records in 1793. At present the disease is declining in the Campagna; but whether owing to a natural dying down or partly or wholly to hygienic measures by man, the author hesitates to affirm.—*J. Bequaert.*

1671. **COUTELEN, F. Contribution aux essais de culture in vitro d'embryons de filaires.** *Bull. Soc. Path. Exotique* 21(4): 316-322. 1928.—The embryos, or microfilariae, of *Icosiella neglecta* (Diesing 1851) found in the blood stream of *Rana esculenta* and *R. temporaria* survived in the hypotonic medium of Ponselle for 12-15 days at 18° C. An increase in length of the larva was not accompanied by any observable alteration in internal structure.—*J. H. Sandground.*

1672. **CRAIG, J. F. Blackhead or infectious enterohepatitis in turkeys.** *World's Poultry Congress* 4(Sect. C): 468-471: résumé sect. 58. 1930.—This is the most common and serious contagious disease of turkeys in Great Britain and Ireland, and has a wide distribution. The author gives a general account of this protozoan disease (*Histomonas meleagris*) and its prevention.

1673. **DORMANNS, ERNST A. Weiterer Beitrag zum Acarinenparasitismus der Affenlunge. [Acariasis of the simian lung.]** *Virchow's Arch. Path. Anat. u. Physiol.* 278(2): 477-480. 4 fig. 1930.—Acariasis in the lungs of a ♀ Macacus (sp. not indicated) led to extensive cavern-formation.

1674. **ESSEX, HIRAM E., and JESSE L. BOLLMAN. Parasitic cirrhosis of the liver in a cat infected with Opisthorchis pseudofelineus and Metorchis complexus.** *Amer. Jour. Trop. Med.* 10(1): 65-70. 4 fig. 1930.—A Persian house cat suffering from an obscure disease was emaciated and markedly jaundiced. Its abdomen was much distended due to large quantities of ascitic fluid in the peritoneal cavity. Paracentesis was performed twice; the 1st time 1,500 cc. of ascitic fluid were removed, and a week later 750 cc. At necropsy the entire liver was firm, hard, greatly enlarged, and weighed 200 gm. The superficial biliary tracts contained sexually mature specimens of *M. complexus* and *O. pseudofelineus.* The liver revealed extensive necrosis of the hepatic cells and extensive hyperplasia of the entire biliary duct system, which suggests a specific cause associated with parasitic infection, probably the intestinal absorption of hepatotoxic agents. Probably uncooked fish was the source of the infestation.—*H. E. Essex.*

1675. **ESQUIER, G. Étude d'un réservoir de virus paludéen dans la région du Kroubs (Départemente de Constantine).** *Arch. Inst. Pasteur Algérie* 7(2): 181-183. 1 map. 1929.—The region studied presents a high splenic index and a high degree of splenic hypertrophy. The valuation of the splenometric index shows still better the intensity of malaria; seldom have such large numbers been found in Algeria. It is concluded that the region considered is very heavily infected with malaria.—*C. Dawley.*

1676. **FAIRLEY, N. HAMILTON, and F. JASUDASAN. Studies in Schistosoma spindale. Part I. The infective rate, seasonal incidence and source of supply of infected molluscs.** *Indian Med. Res. Mem.* 17: pp. 1-10. 2 pl. 1930.—Owing to the group nature of the biological tests for bilharzia, any species of mollusc harbouring bilharzia cercariae and possessing a mammalian definitive host may be used for antigen manufacture. In selecting material for this purpose the livers must be fresh and heavily infected with mature cercariae. Snails (*Planorbis exustus*) were examined (236,354) from 1922 to 1925; 4,738 harbored cercariae of *S. spindale,* the infective rate averaging 20 per 1,000. A definite seasonal incidence was demonstrated; the lowest infective rates were observed during the monsoon months from June to Sept., the highest in the cool period from Nov. to March. Egyptian figures were graphed for comparison, and a similar seasonal variation was demonstrated. The infective rate was higher than in India and averaged 180 per 1,000. The optimum time for collecting infected

molluscs for antigen manufacture in both Western India and Egypt is during the cool weather. In making snail surveys the seasonal factor should receive consideration. —*Authors' summary.*

1677. **FAIRLEY, N. HAMILTON, and F. JASUDASAN. Studies in Schistosoma spindale. Part II. The definitive hosts of S. spindale with special reference to alimentary infection in ruminants.** *Indian Med. Res. Mem.* 17: pp. 11-15. 1930.—Many animals (251) were examined for schistosomiasis. Both goats and cattle harboured *S. spindale,* and the previous suggestion that the water buffalo would be found an important definitive host of this parasite was confirmed. Owing to the peculiar anatomical and physiological differences in the stomach of these ruminants, alimentary infection is regarded as more important than in other mammals. The alkaline or neutral reaction of the contents of the rumen, reticulum and omasum must predispose to gastric invasion not only by prolonging the life of the cercariae but also by increasing the area of mucosa available for invasion. Cercarial invasion via the upper alimentary tract appears to be the usual mode of infestation in goats. Goats were successfully infected with cercariae in drinking water pipetted into the buccal cavity and by direct introduction into the rumen by means of a stomach tube. The effect of achlorhydria and subacidity of the gastric contents in predisposing to alimentary infection in man is briefly discussed.—*Authors' summary.*

1678. **FANTHAM, H. B. Some parasitic protozoa found in South Africa.** British Assoc. Advanc. Sci. Rept. 97th meeting [South Africa] 335-336. 1929(1930).—Abstract.

1679. **FELDMANN, I. Bemerkungen zu der VII. Mitteilung von R. Doerr und G. W. Schmidt: "Studien über den Mechanismus der Trichinelleninfektion."** *Zentralbl. Bakt. Abt. I. Orig.* 117(7/8): 498-499. 1930.—The rare occurrence of Trichinella infection in ducks, doves and chickens (which are not immune as shown by experimental infection) may be due to the greater acidity of the intestinal content of birds, which promotes more rapid elimination of the parasites from the intestine, and thus reduces the chances of penetration of the bird intestinal wall as compared with that of mammals.

1680. **FINZI, BRUNO. Parassitismo di Mermis in un' operaia di Camponotus herculeanus L. [Mermis parasitizing a worker of C. herculeanus.]** *Boll. Soc. Ent. Ital.* 62(7): 133-135. 1 fig. 1930.—A *C. herculeanus,** parasitized by *Mermis* in Italy, was abnormal in having a reduced thorax and an enlarged abdomen.

1681. **FRANCAVIGLIA, M. CONDORELLI. La diffusione dell'ascaridiosi in talune località della provincia di Catanzaro. [Distribution of ascariasis in certain localities in the province of Catanzaro, Italy.]** *Atti Accad. Gioenia Sci. Nat. Catania* 15(Mem. 1): 1-5. 1927.

1682. **FRANCHINI, GIUSEPPE. Su un caso di coccidiosi umana di "Isospora hominis" Rivolta. [Coccidiosis in man, due to I. hominis.]** *Arch. Ital. Sci. Med. Coloniale* 8(6): 305-311. 6 fig. 1927.—One of the few cases of this coccidium reported from Italy. Infection from a cat is suspected.—*P. Popenoe.*

1683. **GALLI-VALERIO, B. La méningo-encéphalomyélite des lapins à coccidiase et le problème de l'étiologie des encéphalites.** *Zeitschr. Immunitätsforsch. u. Exp. Therap.* 65(3/4): 325-330. 1930.—In certain instances rabbits infected with coccidia developed an encephalitis, proved by histological examination, which was not transmissible. The author believes this to be due to a toxin, and thinks that in numerous other infections toxins are produced which result in typical encephalitis. —*N. W. Larkum.*

1684. **GARIN, CH., S. DOUBROW, et H. MOUNIER. Quelques particularités dans l'évolution de l'ankylostomose.** *Compt. Rend. Soc. Biol.* 98(1): 44-45. 1928.—Brief observations on egg counting technique; correlation of symptoms with degree of infection; and various blood modifications during hookworm disease.

1685. **HALL, MAURICE C. The wide field of veterinary parasitology.** *Jour. Parasitol.* 16(4): 175-184. 1930.—As a field of medical zoology, parasitology may call for a knowledge of taxonomy, morphology, life histories, pathology, pharmacology, therapeutics, prophylaxis of parasitisms, agricultural procedures, physics, chemistry, physiology, entomology and related zoological sciences, French, German and Latin, a sound knowledge of English grammar, familiarity with bibliographic methods, sound training in laboratory technic, a knowledge of professional ethics, and a capacity for hard and dirty work. Graduate students show a lack of information in regard to research methods, modes of experimental attack, need for adequate checks, and as to what may be safely concluded from given data. Graduate schools should direct work, rather than assign problems and allow the student to sink or swim alone. The Code of Ethics of the Helminthological Society of Washington is published as an appendix to the paper.—*M. C. Hall.*

1686. **HEGNER, ROBERT. Endolimax amoebae in the vagina of Rhesus monkeys.** *Jour. Parasitol.* 16(2): 91-92. 1 fig. 1929.—The amoebae were indistinguishable morphologically from *E. nana.* In only 1 out of 24 examinations was the presence correlated with demonstration of *Endolimax* in feces.

1687. **HERRMANN, OTTO, und A. MALININA. Über die Dauer der Inkubation bei Malaria.** *Arch. Schiffs- u. Trop.-Hyg.* 32(10): 506-510. 1928.—A long incubation period as causing the first spring cases is considered unproved. A part of them may be relapses after prophylactic quinine, most of them relapses the first attacks of which remained unobserved.—*A. de Buck.*

1688. **HOEPPLI, R., und P. REGENDANZ. Beiträge zur Pathogenese und Histopathologie der Trypanosomeninfektionen der Tiere. II. Histologischer Teil. Gewebsveränderungen bei Trypanosomeninfektionen der Tiere, by R. HOEPPLI.** *Arch. Schiffs- u. Tropen-Hyg.* 34(2): 67-99. 11 fig. 1930.—The nature of pathologic changes in 37 experimental animals (apes, dogs, cats, guinea pigs, rabbits and hamsters) did not depend on the species of trypanosome but on the duration of infection and to some degree on the species of experimental animal; e.g., in apes inflammatory changes of the myocardium were observed rather frequently, but not in cats and dogs. The most notable histologic changes were myocarditis and pericarditis (with infiltration of numerous trypanosomes into the foci of inflammation) and degeneration of the lens, iridocyclitis and conjunctivitis (with infiltration of trypanosomes into the subconjunctival tissue, the ciliary body, and the iris). In the spleen and lymph-nodes the lymphocytes were gradually replaced by plasma cells, with infiltration of numerous macrophages. In the brain rapidly fatal infections produced degeneration of the ganglion cells. Liver and lungs showed numerous macrophages; only 4 times were rather advanced parenchymatous degenerations found and small necrotic liver spots. The epithelium of the urinary tubules was frequently injured, but the glomeruli were usually unchanged. The cells predominating in the inflammatory changes of the organs were small round ones and macrophages, accompanied by a few plasma cells and polymorphonuclear leukocytes. In addition to the heart muscle and the eye, cellular infiltration was found in the periportal tissue of the liver, in the meninges, in the choroid plexus of the lateral ventricle, in the interstitial tissues of the testicles and kidneys, in the striped musculature, and in the corium. Trypanosomes were found in the blood-vessels in sectional preparations of almost all organs.—*Authors' summary (transl.).*

1689. **HUNTER, GEORGE W. III, and WANDA S. HUNTER. Further experimental studies on the bass tapeworm Proteocephalus ambloplitis (Leidy).** *Rept. Biol. Surv. Erie-Niagara System in Suppl. 18th Ann. Rept. New York State Conserv. Dept.* 1928: 198-207. 2 pl. 1929.—Experimental evidence adds *Cyclops vulgaris* and *Eucyclops agilis* (Copepoda) to the list of 1st intermediate hosts; *Ambloplitis rupestris, Perca flavescens* and *Fundulus diaphanus* as 2nd intermediate hosts;

and *Micropterus dolomieu* as a definitive host. The paper also includes a record of examinations made on *Stizostedion vitreum, S. canadense griseum, Esox lucius* and *Lota maculosa* for the plerocercoid of *Diphyllobothrium latum*.—*G. W. Hunter, III.*

1690. **HUNTER, GEORGE W. III., and WANDA SANBORN HUNTER. Studies on the parasites of fishes of the Lake Champlain Watershed.** New York State Conserv. Dept. Suppl. to 19th Ann. Rept. p. 241-260. 5 fig. 1929(1930).—Experiments on the 1st intermediate host of the bass tapeworm, *Proteocephalus ambloplitis* (Leidy) showed that periods of freezing or desiccation destroy the copepods. Unsuccessful experiments to infect Cladocera with eggs of *P. ambloplitis* indicated the desirability of utilizing Cladocera as food for young bass in controlling the tapeworm. Copepods from bass nests during their breeding season showed 25% higher infection with *P. ambloplitis* procercoids than at other times. Infection data are cited for adult bass from the Lake Champlain watershed. Ecological data are presented on the infection of the Adirondack frostfish (*Prosopium quadrilaterale*), smelt (*Osmerus mordax*), northern pike (*Esox lucius*), yellow perch (*Perca flavescens*), scaled ling (*Amia calva*) and bill fish (*Lepisosteus osseus*). Metacercariae (*Neascus bulboglossa*) were found in 2 new hosts, young northern pike (*E. lucius*) and horned dace (*Semotilus atromaculatus*).—*G. W. Hunter, III.*

1691. **ITAGAKI, SHIRO. The nature of the parasitic nodules in the caecal wall of fowls and the development of Heterakis vesicularis.** *World's Poultry Congress* 4 (Sect. C): 481-483; résumé sect. 60. 1930.—Of 620 fowls examined, 80 had helminthic nodules in the caecal wall, each containing one or more heterakid worms in various stages of development. No difference in the larval worms was noticed between those in the nodules of the caecum and of the small intestine. Both larval worms may be identical. Probably some of the larvae of *Ascaridia perspicillum* become embedded in the muscular wall of the small intestine, where they produce nodules, while others enter the caecum and produce similar nodules in the submucosa. Experiments to study *H. vesicularis* development in these regions are reported.

1692. **JAHNEL, F., und A. PENTSCHEW. Ueber "Infektionen" von Vögeln mit Rekurrensspirochäten und Säugetiertrypanosomen.** *Centralbl. Bakt. Abt. I. Orig.* 115 (3/4): 167-168. 1929.—Relapsing fever spirochaetes from mice were inoculated into the pectoral muscle of canaries. They appeared in the canary blood about 1 hr. later and were present for about a day. Trypanosome infections from mammal to bird disappeared even more rapidly.

1693. **KLEIN, B., R. LOPATIZKI, und P. SOLITERMAN. Beiträge über den Erreger der experimentellen perniziösen Anämie.** *Arch. Schiffs- u. Tropen-Hyg.* 34 (5): 274-282. 1930.—The rat Bartonella was successfully implanted in guinea pigs and rabbits by peritoneal inoculation of infected liver. Simultaneous subcutaneous injection of a typhoid culture apparently broke down the host resistance so that the Bartonellae could be found in the erythrocytes after 2-4 days. Only the guinea pig experiments are here described. The course of infection was symptomless. The strain of Bartonellae survived 23 pasages from guinea pig to guinea pig (3 mo.). In 8 out of 11 splenectomized guinea pigs not inoculated with rat Bartonellae infection with identical Bartonellae was demonstrated, in 1 case with a transitory blood phenomenon of pernicious type. The Bartonellae originating in guinea pigs attested their identity with murine Bartonellae by infecting rats and mice, producing in the latter outspoken or fatal anemia. In 2 cases of human anemia a Bartonella-like picture was found.

1694. **KOPPERI, A. J. Untersuchungen über die ciliaten Infusorien im Coecum des Pferdes.** *Ann. Soc. Zool.-Bot. Fennicae Vanamo* 8: 34-47. 6 fig. 1929.—In Finland, masses of ciliates were found in every cecum of 25 horses. Of the 15 well established non-pathogenic spp. previously known, the following 12 were found: *Bütschlia postciliata, Didesmis quadrata, D. ovalis, Blepharoprosthium pireum, Blepharosphaera intestinalis, Paraisotricha colpoidea, P. truncata, P. ovalis, Blepharocorys uncinata, B. jubata, B. equi,* and *Cycloposthium bipalmatum.* The 3 absent were: *Blepharocodon appendiculatus, Paraisotricha oblonga* and *Blepharocorys valvata. B. equi,* described hitherto only from California, proved the commonest of its genus in Finland. Encystment was observed in *P. colpoidea* and *C. bipalmatum.*—*A. J. Kopperi (transl. by M. C. Marsh).*

1695. **KORKE, V. T. Observations on the correlation between the incidence of filarial infection in the human host and in the insect carrier in relation to terrain. Part V.** *Indian Jour. Med. Res.* 18(1): 319-331. 1 map. 1930.—An investigation into filariasis in the provinces of Bihar and Orissa. *Culex fatigans* is the domestic mosquito in these areas. A list of the other spp. of mosquitoes found is given. A map shows the division of the provinces into belts and type areas.—*S. Ribeiro.*

1696. **KORKE, V. T. Observations on the characters of filarial endemic areas in Bihar and Orissa. Part VI.** *Indian Jour. Med. Res.* 18(1): 333-336. 1930.—The author deals with prevention and points out the physical and biological factors responsible in an intense endemic area of filariasis, such as nature of the land and the presence of the insect carrier (in this case *Culex fatigans*).—*S. Ribeiro.*

1697. **LAIGRET, J. Onchocercose humaine et éléphantiasis au Soudan français.** *Bull. Soc. Path. Exotique* 22(6): 499-506. 4 pl. 1929.—Infection with *Onchocerca volvulus* in certain regions of the Sudan is as high as in Equatorial Africa. The area covered extends as far north as the pre-desert zone of the Sahel. Here onchocerciasis occurs with cutaneous manifestations of xerodermy and a very pronounced pseudo-ichthyosis due to constant passage of larvae through the skin. To this dermatosis there may be added, as to the healthy skin, ordinary lesions of a dermo-epidermitis, which has led to the appellation, improper in the author's opinion, filarial itch or prurigo. In the absence of *Filaria bancrofti,* there appears to be in the Sudan, as in the Congo and other regions of Africa, a close relationship between *O. volvulus* and tropical elephantiasis. Early slightly developed elephantiasis is always accompanied by the microfilariae of *O. volvulus,* demonstrated by the finding of cysts, by puncture of ganglia and by skin sections of elephantiasic tissues. This frequence of *O. volvulus,* the tenacious character of certain manifestations of this parasitism, its reverberation on general economy which is still poorly known, present from the viewpoint of the military questions that deserve study.—*J. H. Sandground.*

1698. **LEASURE, E. E. Anaplasmosis in Kansas.** *Cornell Vet.* 20(3): 304-306. 1930.

1699. **LEHMANN, JOACHIM. Über Hirncysticercen.** *Frankfurter Zeitschr. Path.* 38(3): 439-449. 7 fig. 1929.—Necropsy findings in a case of multilocular *Cysticercus cellulosae* are discussed. The patient had suffered from epileptiform attacks. Numerous cysts, partly sterile, partly viable, were found in the cerebral cortex, in the subcortical layers, and in the 4th ventricle.

1700. **LÓPEZ-NEYRA, CARLOS RODRIGUEZ. Primer caso de parasitismo por el Stephanurus dentatus en Europa. [First case of parasitism in Europe with S. dentatus.]** *Mem. R. Soc. Españ. Hist. Nat.* 15(1): 241-245. 1929.—This constitutes the 1st authentic report of this nematode parasite in Europe. The worms, 6 ♂ and 4 ♀, were obtained from a renal cyst of a pig raised in Granada. Discrepancies in existing descriptions of the parasite have led to an enumeration and comparison of its important morphological characters.—*M. A. Tubangui.*

1701. **[MAGNITSKIĬ, V. I.] МАГНИТСКИЙ, В. И. Очерк проведения противомалярийных мероприятий в Западной Бухаре в 1922-1925 гг. [A sketch of the anti-malaria campaigns in Western Bokhara (Central Asia) in 1922-1925.]** Доклады Академии Наук СССР. (*Compt. Rend. Acad. Sci. URSS. A*) 1927(11): 169-174. 1927.

1702. **MAPLESTONE, P. A. A simple method of**

preserving faeces containing hookworm eggs. *Indian Jour. Med. Res.* 16(3): 675-682. 1 pl. 1929.—The method described is for transportation of human feces to a central laboratory by post. Specimens are secured in the usual small tins. Then 4 cc. of feces are measured into small cylindrical containers of fairly stiff writing paper; these cylinders, fashioned over an appropriate syringe barrel or similarly shaped piece of wood, are about 15 mm. diam. × 21 mm. deep. After filling they are dropped into bottles of 27 cc. capacity, with inside neck diam. of 18 mm.; 20 cc. of 2% antiformin is added, and the corks tied on. Bottles are shipped in boxes. At the laboratory, the paper, now free, is removed from a bottle, the contents well shaken, and 6 cc. of the mixture (equivalent of 1 cc. of feces with 5 cc. of antiformin) transferred to a Lane tube for centrifuging. If positive for ova, the balance in the bottle (equivalent of 3 cc. of feces with 15 cc. of antiformin) is transferred to a dilution tube, N/10 NaOH added to make 45 cc. of mixture, and submitted to routine dilution count. Detailed experiments indicate that there is little if any loss of hookworm ova by either method of examination, even at incubator temp. within 18 days. The author emphasizes transference of the original sample to the antiformin bottle on the day of collection.—*N. R. Stoll.*

1703. **MARÍN, RAFAEL ANGEL. Studies on schistosomiasis (S. mansoni) in Porto Rico.** *Porto Rico Rev. Publ. Health and Trop. Med.* 3(10): 397-402. 4 fig. 1928.—Cercariae of 4 kinds have been so far obtained from *Planorbis guadeloupensis,* the intermediate host of *Schistosoma mansoni* in Porto Rico. P. R. Cercaria I is that of *S. mansoni.* P. R. Cercaria II is a fork-tailed one with a pair of eye-spots and a tail at a distinct angle with the body. P. R. Cercaria III is an echinostome without a collar of spines; small fish are probably its 2nd intermediate host. P. R. Cercaria IV is an echinostome with a tail broader than the body, a condition apparently unknown among echinostome cercariae. Evidence suggests that P. R. Cercariae III and IV have not been previously identified though the adult trematodes may be known.—*From author's summary.*

1704. **MATHESON, D. C. Avian coccidiosis.** *World's Poultry Congress* 4(Sect. C): 439-444; résumé sect., 55. 1930.—Coccidiosis occurred in 7.5% of 1,426 fowls (including chickens) examined during 16 yrs. Examination of the feces of 1,094 fowls surviving from flocks affected with coccidiosis as chickens showed 5.7% to be carriers of coccidia. While an occasional outbreak in Great Britain may occur in Jan. or Feb., the disease is more common in Mar., the number of outbreaks rising steadily thereafter until a maximum is reached in June; a steady decline then until Oct. is followed by a rise again. Preventive and control measures are suggested.

1705. **MATTES, O. Bau und Verhalten der Entwicklungsstadien von Fasciola hepatica im Zwischenwirt Limnaea truncatula an Hand von Präparaten, die durch künstliche Infektion gewonnen wurden. [Structure and relationships of the developmental stages of F. hepatica in the intermediate host L. truncatula, based on preparations from experimental infestations.]** *Zool. Anzeiger, Suppl. Bd. (Verhandl. Deutsch. Zool. Ges. E. V. 1929)* 4: 266. 1929.

1706. **MAYER, MARTIN. Neuere Ergebnisse von Kultur- und Tierversuchen mit Leishmanien.** *Arch. Schiffs- u. Tropen-Hyg.* 33(Beih. 3): 94-97. 2 fig. 1929.—The Chinese hamster was less suitable for experiments with Oriental boil than with kala-azar. Only 1 strain of the former from Palestine produced severe local phenomena and in 3 cases general infection also.

1707. **MAYER, MARTIN, und JYOTIS CHANDRA RAY. Züchtung und Differential-diagnose verschiedener Leishmanien (Kalaazar, Orientbeule und brasilianische Leishmaniose) auf festen Nährböden.** *Arch. Schiffs- u. Tropen-Hyg.* 32(6): 277-287. 19 fig. 1928.—Culture on horse blood agar plates by Noller's technique (agar 30 gm., glucose 20 gm., weakly alkaline Leibig's broth 1000 cc.) gave characteristic growth differentiation between kala-azar, various strains of Oriental boil and Brazilian leishmaniasis. *Leishmania donovani* formed small thick colonies without spreading. *L. tropica* from Palestine grew upward with wide parallel runners which never ramified. *L. tropica,* 2 strains from Turkestan, showed primarily very marked outgrowths as ramifying nets: one a rank growth, the other very delicate. *L. tropica* var. *americana* from Brazil grew meagerly without branching, but showed rapid surface growth. Both wet preparations from surface growth and dry smears showed characteristic forms of all parasites.—*D. Koch.*

1708. **MOMMA, KENJI. Notes on modes of rat infestation with Hepaticola hepatica.** *Ann. Trop. Med. and Parasitol.* 24(1): 109-113. 1930.—*H. hepatica* is the most common nematode parasite in the liver of the house rat. Infestation is 57.2%, with a rate lowest in summer, increasing through autumn and winter until the maximum in the succeeding spring. No eggs were found in the intestines of 29 infected rats. Eggs dried for about 1 mo. or passed through the intestinal tract of the cat or the fly do not lose their power of development. The writer believes that the fly is the chief disseminator of the eggs.

1709. **NAPIER, L. EVERARD, and G. N. SEN. An investigation to decide the most suitable dilutions for the performance of the antimony test for kala-azar.** *Indian Jour. Med. Res.* 17(4): 1139-1151. 1930.—Experiments with different dilutions of both serum and antimony compound were tried to find which combination gave the most specific results. Four groups of 25 patients each were selected; the 1st 2 groups consisted of patients in whom a definite diagnosis had been made by the aldehyde test, 25 kala-azar patients and 25 controls; the other 2 groups consisted of cases in which the aldehyde test gave an indeterminate result; of these again 25 were kala-azar patients and 25 culturally proved not to be kala-azar. The most satisfactory results were obtained by the addition of 25% serum to either 4, 2, 1, or 0.5% ureastibamine. By adding this strength of serum to 1% antimony compound, the readings in the series were 58 correct, 7 incorrect, and 35 doubtful. Almost the same mixture of antimony compound and serum can be obtained by adding 2 drops (0.125 cc.) of serum to 1 cc. of 0.5% ureastibamine; this, a more practical method, is suggested for the clinical application of the test. Preliminary clinical trial gave satisfactory results.

1710. **NOTO-SOEDIRO, R. Paragonimus westermani (Kerbert) bij een kat. [P. westermani in a native cat.]** *Nederlandsch-Indische Bladen Diergeneeskunde* 42(3): 278-280. 1930.

1711. **[OGANOV, L. I.] ОГАНОВ, Л. И. Малярия в Скопинском уезде и меры борьбы с ней. (Contribution à l'étude du Paludisme dans l'ouezd de Scopine, Gouvernement de Riazan.)** [In Russian, with French summary, p. 69.] *Russian Jour. Trop. Med.* 6(1): 15-32. 1928.—The author captured, in western Scopine, *Anopheles maculipennis* Mg., *A. bifurcatus* L., *Aedes excrucians, A. dorsalis* and *Culex pipiens.* Blood from 7,241 individuals showed 1,346 infections with *Plasmodium vivax,* 195 with *P. praecox* and 43 mixed infections (*vivax*+*praecox*). *P. vivax* infection is autochthonous and that of *P. praecox* imported.—*Author's summary (transl.).*

1712. **OKA, ASAJIRO. Sur la présence de la Dinobdella ferox en Formose. [D. ferox in Formosa.]** *Proc. Imp. Acad. [Tokyo]* 5(5): 210-212. 2 fig. 1929.—Reported as taken from the larynx of man and the nares of a buffalo. Notes on external morphology are given.—*J. P. Moore.*

1713. **PENKACKI, C. Recherches sur les vers parasites dans l'intestin du chien.** *Bull. Internat. Acad. Polonaise Sci. et Let. Cl. Sci. Math. et Nat. Sér. B: Sci. Nat. (II)* 1929(3/6): 215-227. 1929.—In 2 yrs. 400 dogs were examined at Varsovi. *Echinochasmus perfoliatus* was found in 4.5%, *Alaria alata* in 1.5%, *Diphyllobothrium latum* in 1%, *Taenia pisiformis* in 4%, *T. hydatigena* in 7.25%, *Echinococcus granulosus* in 7%, *Mesocestoides lineatus* in 7.75%, *Dipylidium* sp. in 51%, *Uncinaria stenocephalus*

in 37.5%, *Toxocara canis* in 9.75%, and *Toxascaris lenina* in 15%. The interrelations and the amount of parasitism in individual hosts is given, 5 spp. in a host being once reported. A summary table of previous reports of intestinal parasites of dogs is included. A brief statement of the hatching of the eggs of *D. latum* and of the comparative morphology of the ascarids is included. No attempt at specific identification of *Dipylidium* is made but the author believes that *D. caninum* predominates.—*G. F. Otto.*

1715. **PHISALIX, M. Les hémogrégarines du Bufo agua Latr. (syn. Bufo marinus L.).** *Bull. Soc. Path. Exotique* 23(4): 372-377. 1930.—In 20 toads of the Brazilian *B. agua* Latr. were found filaria embryos, young macrogametocytes of an as yet unidentified coccidium, and 4 hemogregarines, including 3 already described and *Haemogregarina aguai* (p. 375). The stages of all spp. are described.

1716. **PILLERS, NOËL A. W. Notes on parasites in 1929.** *Vet. Rec.* 10(21): 448-450. 1930.—A list of 47 parasites of rat, mice, fish, rabbit and 8 domestic animals includes 1 fungus, 5 protozoa, 2 trematodes, 11 cestodes, 8 nematodes, 9 acarines, 1 linguatulid and 10 insects.

1717. **PIROT. Nécatorose chez les matelots indigènes du recrutement indochinois, embarqués sur un bâtiment des forces navales en Extrême-Orient. [Necator infection of the native seamen of the Indo-China recruitment.]** *Arch. Méd. et Pharm. Navales* 119(2): 284-292. 1929.—*N. americanus* was found in 68-78% of recruits examined.

1718. **PORTER, ANNIE. Some South African larval flukes.** British Assoc. Advanc. Sci. Rept. 97th meeting [South Africa] 337. 1929(1930).—Abstract.

1719. **PORTER, ANNIE. Some remarks on the hookworm problem in South Africa.** British Assoc. Advanc. Sci. Rept. 97th meeting [South Africa] 337-338. 1929 (1930).—Abstract.

1720. **PURVIS, J. B. Further parasites of domestic animals in Malaya.** *Vet. Rec.* [*London*] 10(32): 750. 1930.—A list.

1721. **RATCLIFFE, HERBERT L. The relations of Endamoeba muris and Chilomastix bettencourti to the diet and intestinal conditions of rats.** *Jour. Parasitol.* 16(2): 75-80. 1929.—Ten rats infected with each organism were fed experimental diets, and 5 infected with each were kept on stock diet as controls. Observations at 25-day intervals showed that infections with both *E. muris* and *C. bettencourti* in rats on a diet which promoted a predominance of aciduric bacteria were light, the numbers being about the same as for *Trichomonas parva* in rats on this diet. When a diet promoting the growth of Gram-negative bacteria was fed, both organisms increased in numbers. A diet which increased the proteolytic anaerobes and decreased both the Gram-negative and Gram-positive aerobes, caused both protozoa to decrease in numbers, but no case was negative for either organism. Infections in control animals on the stock diet did not vary appreciably. *E. muris* and *C. bettencourti* are thus somewhat similar to *T. parva* in relation to the intestinal bacteria of rats. Definite variation in numbers appeared with 2 high protein diets but neither species was greatly affected.—*Author's summary.*

1722. **REGENDANZ, P. Über die Ansammlung von Trypanosomen in den Flüssigkeiten der Körperhöhlen und ihre Bedeutung für das Entstehen von Gewebsveränderungen. (Nach experimentellen Untersuchungen.)** *Arch. Schiffs- u. Tropen-Hyg.* 33(Beih. 3): 97-101. 1929.—The effects of *Trypanosoma gambiense, T. rhodesiense, T. brucei,* and *T. equiperdum* were studied on rats, hamsters, rabbits, cats, dogs and monkeys. The tissue changes included epicarditis, myocarditis, conjunctivitis and iritis, always accompanied by edema of the affected tissue. The path of the trypanosomes was traced from the bloodstream into the other fluid and tissues. Toxins from the parasites probably disturb the local circulation, producing a weak diapedesis, in the wake of which the trypanosomes penetrate surrounding tissues. Details and number of experiments are given in Hoeppli's paper, *Ibid.,* 101-113.

1723. **REGENDANZ, P. Der Verlauf der Infektion mit Schizotrypanum cruzi (Chagas) bei jungen Ratten und über die Unempfänglichkeit erwachsener Ratten für Schizotrypanum.** *Zentralbl. Bakt. Abt. I. Orig.* 116(4/5): 256-264. 1930.—The Chagas' disease organism, *S cruzi,* was injected into 25 young rats aged 2-30 days, and into an unspecified number of old rats. No infection was ever produced in an adult; the younger the rat, the more susceptible and the longer and more intense the infection. The incubation period was 7-13 days. Parasites were not demonstrable in the blood after 7-8 weeks, no matter what the age or how severe the infection. Infections ended fatally in 6 (25%) of the young rats; in the others the parasites disappeared from the blood and the infection apparently came to an end. The course and outcome in rats corresponds generally with the acute form of human Chagas' disease; there are points of similarity also in the immunity of adult rats and of adult human beings or older children. The serum of adult rats afforded mice no protection against schizotrypanum infection. Neither castration nor implantation of testicles, nor yet splenectomy, affected immunity or susceptibility.

1724. **REITLER, RUDOLF. Über eine Varietät des Quartanaparasiten.** *Arch. Schiffs- u. Tropen-Hyg.* 33(2): 93-95. 1 fig. 1929.—A peculiar type of *Plasmodium malariae* was found in 3 Arab children of Upper Galilee. The rings show a marked development of chromatin in the form of granules throughout the parasite; trophozoites are band-like, but differ from the usual bandforms of quartan; the schizont pigment is finer than usual for quartan but coarser than for *P. vivax;* schizonts divide into 10-12 merozoites; infected corpuscles stain less easily than normal, but are not increased in size; there are no Maurer's or Schüffner's dots.—*W. H. Taliaferro.*

1725. **RILEY, W. A., and R. O. CHRISTENSON. Guide to the study of animal parasites.** 126p. 33 fig. McGraw Hill Book Co.: New York, 1930. Pr. $1.50.—A laboratory manual written from the viewpoint of the teaching parasitologist for use by students with a background of general zoology. The text covers the parasitic protozoa and helminths with brief references to the annulata and arthropoda. The appendix contains useful directions for the collection and technical preparation of material as well as a bibliography and a list of sources of materials.—*L. M. Dickerson.*

1726. **ROBERTSON, ANDREW. Note on a trypanosome morphologically similar to Trypanosoma cruzi Chagas, 1909, found in an opossum, Didelphis marsupialis, captured at Tela, Honduras, Central America.** United Fruit Co., Med. Dept. 18th Ann. Rept. pp. 293-310. 2 pl., 6 fig. 1929.—The trypanosomes in the blood were morphologically similar to *T. cruzi* except that in some the nucleus was rather nearer the anterior or flagellar end of the body. Developmental stages were found in the heart muscle. *Cimex rotundatus,* the local bedbug, was successfully infected by feeding on the opossum; it was still infected 3 mo. later. A guinea pig, successfully inoculated with opossum blood, showed blood forms identical with those from the opossum; the infection was transient (2-2½ weeks). A guinea pig inoculated with the infected dejecta of *Cimex* developed an infection in the peripheral blood 1 mo. later. The organism, isolated in culture on Wenyon's modification of Noguchi's blood agar medium, showed forms corresponding closely to those in culture of a known strain of *T. cruzi.* A guinea pig showed trypanosomes in its blood 1 mo. after inoculation with the cultural forms; the infection also proved transient (21 days). Tela, Honduras, is some 2,000 miles from what has hitherto been regarded as the endemic zone of this form of trypanosomiasis.—*Author's summary.*

1727. **ROSS, RONALD. The amount of malaria de-**

pends on the numbers of the carriers. 14p. John Murray: London, 1929. Price 2s. 6d.

1728. **RUGE, REINHOLD. Ein neues und ein altes Problem der Malariaforschung.** *Arch. Schiffs- u. Tropen-Hyg.* 32(6): 287-291. 1928.—The author considers the gametocyte freeness of strains of inoculation malaria, and the parthenogenetic theory of relapse, to be contradicted by recent results and experiences.—*A. de Buck.*

1729. **SASSUCHIN, D. H. Zur Frage über die Parasiten der Protozoen. Parasiten von Nyctotherus ovalis Leidy.** *Arch. Protistenk.* 64(1/2): 61-70. 2 pl., 3 fig. 1928.—Approximately 20% of the *N. ovalis* in the gut of *Periplaneta orientalis* were found to be infected. Descriptions of the 2 parasites are based on observations of moist-chamber cultures, micro-chemical reactions, and permanent preparations stained in toto and in sections by several methods. No specific names are assigned. One form is considered similar to the *Sphaerita* in certain amoebas and the other bacterium-like.—*L. M. Dickerson.*

1730. **SCHAPIRO, LOUIS, and W. W. CORT. A study of the relation of the dry season to the level of helminth infestation in a Panama village.** *Amer. Jour. Hyg.* 12(3): 699-708. 1930.—Examinations by the dilution egg count method were undertaken in Dolega, where the rainfall is over 100 in. a yr. and the yards densely shaded. A preliminary examination of 213 out of a population of 539 showed a very heavy hookworm infestation of the type found in the Panama uplands, a rather low Ascaris count, and one of the heaviest Trichuris infestations ever recorded by the egg-counting method. Two series of counts of 100 individuals were made about 2 mo. after the end of both the rainy and the dry seasons. The close correspondence of these check counts indicated that the egg-counting technic used was uniform throughout the time of the studies. A comparison of the ave. count of the post-rainy season with that of the post-dry season showed an increase for hookworm, Ascaris and Trichuris, entirely due to great increases in a very small number of cases (5 for hookworm and 2 each for Ascaris and Trichuris). No reduction in infestation level occurred for any of the 3 worms over the 4 mo. of the dry season. To what extent this is due to reinfection during the dry season or to persistence over this period of worms already present cannot be determined.—*Authors' summary.*

1731. **SINTON, J. A., and H. W. MULLIGAN. The staining of malarial parasites in blood smears by the iron-haematoxylin method.** *Indian Jour. Med. Res.* 17 (4): 1329-1332. 1930.—By use of acid fixatives (Carnoy, Gilson), the erythrocytes were dehemoglobinized; with the iron thus removed, the erythrocytes remained almost completely unstained and did not obscure the parasites.

1732. **SIOE, KWA TJAON. Strongyloidosis and its treatment with gentian violet.** *Far East. Assoc. Trop. Med. Trans. 7th Congr. Brit. India* 3: 200-204. 1927. [1928].—Gentian violet tablets administered per os killed *Strongyloides* within a short time. Gentian violet probably acts directly on the worms; in vitro it has no more effect than other drugs against the larvae.

1733. **SPINDLER, L. A. A study of the temperature and moisture requirements in the development of the eggs of the dog trichurid (Trichuris vulpis).** *Jour. Parasitol.* 16(1): 41-46. 1929. Eggs of *T. vulpis* developed and became embryonated in 12-15 days at 37° C. Development at 30° C. was nearly as rapid, the majority of the eggs being embryonated in 16 days. Development of eggs at 22° C. was much slower, 77% being embryonated in 35 days. When dried on cover glasses and incubated in an atmosphere 57% saturated, at an ave. of 22° C., 97% of the eggs died in 8 days. At 47% saturation at 30° C., 96% died in the same time. At 77% saturation at 22° C., 100% died in 12 days. On slides exposed to the air of the laboratory, 93% of the eggs were dead in 15 days. In a saturated atmosphere at 30° C., eggs failed to develop and died in 12 days. The majority of the eggs under similar conditions at 22° died in a short time, although 24% lived and became embryonated in 38 days. On wet soil in a saturated atmosphere at 22 and 30°, the eggs apparently developed normally, whereas 98% on dry soil at 30° died in 29 days. At 22°, 29% were alive on the 29th day, withstanding conditions of dryness at 22° C. that are fatal at 30° C. Comparison with similar experiments on the eggs of the dog ascarid (*Toxocara canis*) showed, as in the case of the human forms, that *Trichuris* eggs require more moisture for development than those of *Ascaris*.—*Author's summary.*

1734. **STEPHENS, J. W. W. The distribution of blackwater fever in North America.** *Ann. Trop. Med. & Parasitol.* 23(4): 451-479. 2 maps. 1929.—A tabulation of published records.

1735. **STERLING, OKUNIEWSKI, et ROSNOWSKI. Contribution à l'étude de l'épidémiologie et de la clinique de la trichinose.** *Jour. Physiol. et Path. Gén.* 28(2): 387-390. 1930.—Blood examination is valuable in distinguishing trichinosis from painful muscular affections. Eosinophilia, when other parasites are absent, is significant although it does not necessarily show the intensity of the infection. Faecal examination for parasites, cutaneous and serological reactions are of little value. Thymol (10%) in castor oil was given in doses of 4 gm. per diem with good results. An attack of trichinosis confers no immunity.—*W. R. Fearon.*

1739. **TAYLOR, E. LEONARD. Gapes (syngamiasis)—the relation of wild birds to the disease in chicks.** *World's Poultry Congress* 4(Sect. C): 433-438; résumé sect. 54. 1930.—Starlings and rooks frequently carry gapeworms morphologically indistinguishable from *Syngamus trachea* of chicks. Cross infection can be brought about, but experiments suggest that the strains are different, and that a comparatively large dose of starling gapeworms is required to produce chick infection. Gapeworms cannot increase in the body of the host. The succession of generations is slow so that the sudden appearance of a severe outbreak of gapes is improbable. Severe outbreaks must be gradually built up through accumulation of infection on the ground. Recent work suggests that the earthworm acts as a facultative intermediate host, the larvae becoming encysted in its muscular tissue; hence it may possibly act as a collecting reservoir, and in time accumulate enough larvae to constitute an infective dose for the chick. A single *Syngamus* cannot establish itself in the trachea, and the only successful parasites are pairs of ♂ and ♀ in copula. The rate of intake of infective larvae is therefore of some importance, since both ♂ and ♀ larvae must reach the air passages at about the same time. Probably wild bird carriers have not the importance at first suggested in causing losses.—*Author's résumé.*

FILTERABLE VIRUSES, BACTERIOPHAGE, ETC.

GEO. H. SMITH, *Editor*

(See also in this issue the subsection "Infectious Chloroses" in the section Phytopathology; and Entries 386, 1336, 1381, 1434, 1497, 1505, 1546, 1563, 1566, 1587, 1626, 1645, 1653, 1800, 1838)

GENERAL

1743. **BURKE, A. W., and N. C. DAVIS.** Notes on laboratory infections with yellow fever. *Amer. Jour. Trop. Med.* 10(6): 419-426. 1930.—A description of 4 cases of yellow fever among Americans in Bahia, Brazil, at least 3 undoubtedly laboratory infections. Besides clinical details, a discussion is given of the probable mode of infection, virus involved, and probable effects from use of immune serum.—*W. H. Taliaferro.*

1744. **BURNET, F. M.** Bacteriophage activity and the antigenic structure of bacteria. *Jour. Path. & Bact.* 33(3): 647-664. 1930.—Lysis by bacteriophage is preceded by the specific adsorption of the lytic agent on some protein of the bacterial surface, which is apparently related to the heat-stable antigen of the bacterium. It is shown that the simple conception that the point of attack of the bacteriophage and the heat-stable antigen constituents are identical, is not always true. In the complicated Salmonella group it becomes necessary to assume that while the phenomena of development of bacteriophage resistance and serological variation are probably intimately related, the process involves a complicated mechanism of splitting off of fractions and exposure of other portions to the action of suitable agents —a combination of mutation by loss and unmasking of hidden constituents. Experiments are recorded on *B. sanguinarium,* Flexner dysentery bacilli and *Staphylococcus albus.*—*H. S. W.*

1745. **BUSSON, B.** Experimentelle Studien über das Lyssa-Virus. *Zentralbl. Bakt. I. Abt. Orig.* 113(3/4): 290-301. 1929.—Since in some fatal cases of "paralytic accident" following Pasteur treatment fixed virus has been found in the brain, the virus is considered by the author to have been the cause. The experiments of Quast, in which after subcutaneous injection of the virus it was demonstrated in the brain of the healthy animals, are regarded as non-conclusive because the animals were killed too soon; had they lived longer, the virus might have disappeared. Account should be taken of the period of incubation in rabies. If it is long, this need not be due to small dosage or abnormally low virulence of the particular strain. Thus, in several rabbits inoculated with street virus, the brain injected into guinea pigs always killed them in 5-6 days; yet for the submaxillary and parotid glands, the corresponding times were 12-92 days, and in one of the latter cases reinoculation of the guinea pig's brain into another animal produced rabies with correspondingly long incubation. However, this is not the rule. Possibly some of the gland strains contain the virus in a different stage of development from the brain strain.—*C. Prausnitz.*

1746. **BUSSON, B.** Der Einfluss des Aethers und anderer Entfettungsmittel auf das Virus fixe und seine Pathogenität. *Zeitschr. Immunitätsforsch. u. Exp. Therap.* 65(5/6): 465-472. 1930.—Use of di- or trichlorethylene in preparation of fixed virus is recommended. These substances, although having certain objections, are preferable to ether, since they are not explosive or inflammable; objections are easily overcome. —*N. W. Larkum.*

1747. **CHABAL, L.** Conjonctivite infectieuse de Parinaud et fièvre exanthématique méditerranéenne. *Bull. Soc. Path. Exotique* 24(2): 76-80. 1931.—In 6 cases which the author classed as Parinaud's conjunctivitis, there was either a definite history of tick bite or opportunity for its occurrence; in 4 of these cases there was an accompanying more or less general eruption. The author was bitten by a tick, with following Mediterranean exanthematic fever and accompanying conjunctivitis. In an 8th case, characteristic eruption, fever and conjunctivitis were present; this patient owned many dogs. It is concluded that ticks carry the infection of Parinaud's conjunctivitis, and that it may appear as the initial symptom of Mediterranean exanthematic fever and is to be regarded as a local reaction to inoculation.

1748. **CUNNINGHAM, J., M. J. NICHOLAS, and B. N. LAHIRI.** Rabies and anti-rabic treatment. The action of ether on the rabies virus. *Far East. Assoc. Trop. Med. Trans. 7th Cong. Brit. India* 3: 531-536. 1 pl., 1 fig. 1927 [1928].—Different strains of the virus appeared to vary considerably in resistance to ether. If the ether method of attenuating the virus for therapeutic purposes is generally adopted, this factor requires careful consideration.

1749. **DAVIS, NELSON C.** Estudos sobre febre amarella. O effeito do calor e do frio sobre o desenvolvimento da infectividade nos Aedes aegypti. [Yellow fever studies. Effect of heat and cold on the progress of infectivity of A. aegypti.] *Brasil-Med.* 45(4): 77-78. 1931.—Preliminary results.

1750. **DOOREN de JONG, L. E. den.** Studien über Bakteriophagie. I. Ueber Bac. megatherium und den darin anwesenden Bakteriophagen. II. Fortsetzung der Untersuchungen über den Megatherium-Bakteriophagen. *Zentralbl. Bakt. I. Abt. Orig.* 120(1/2): 1-15, 15-23. 8 fig. 1931.—I. Careful pasteurization of a strain of *B. megatherium* produced a non-spore bearing, "mutilated," defective form, which (No. 899) was capable of producing both normal and labile "flatter" colonies. The filtrate of a labile culture had a strong lytic action on another defective *B. megatherium* strain (No. 337). The lytic principle proved to be reinoculable in series, and thereby identical with d'Herelle's bacteriophage. However, since the lytic filtrate could be obtained from a culture heated to 100° C. for 5 min., the possibility of a latent infection appeared to be excluded; the only reasonable explanation of the origin of the bacteriophage appeared to be its production by a bacterial cell which had come from one of the spores surviving pasteurization. The facts that the bacteriophage had been obtained from only 1 strain (No. 899) and was active against only 1 other strain (No. 337), called for a more extended study of the sensitivity of the defective strains. II. Of the "defectives" of 18 *B. megatherium* strains, 10 showed no lytic effect with the bacteriophage of strain 899; a given quantity of the filtrate produced on various smears of a sensitive "defective," varying numbers of concave, pellucid plaques of different dimensions. Cultivation of the insensitive "defectives" on 10% peptone agar elicited marked sensitiveness in most of them, including No. 899, thus demonstrating the possibility of variation in this respect among "defectives" of the same strain. Spore-bearing as well as "defective" derivatives of No. 899, however, contained active bacteriophage, and by this simplified method active filtrates were obtained from Nos. 333 and 897. The lysins from Nos. 899 and 333 appeared to contain 2 bacteriophages: No. 1 formed pellucid plaques of normal type; No. 2, plaques each of which contained a little colony in the center and which were therefore called "point plaques." The lysins of Nos. 333 and 897, especially the latter, appeared to

affect even fewer defective strains than the lysin of No. 899. The facts that (1) various defective derivatives of the same megatherium strain present very different sensitivity toward a single bacteriophage, and that (2) a single defective strain evinces very different degrees of sensitivity toward 3 different bacteriophages, indicate that lysis (and therefore plaque formation) can occur only when the sensitivity of the defective strain and the activity of the lysin are adapted to each other. Lack of lysis does not prove the absence of bacteriophage. Most cases of pseudobacteriophagy described in the literature, and Sohngen's hetero-bacteriolysis, must apparently be reckoned as true bacteriophagy. The number of pellucid plaques produced by a given filtrate is never an absolute measure of the number of bacteriophage bodies present. This study shows that the production of bacteriophage is in all probability a general property of *B. megatherium*.

1751. GROTH, A. Sind Varizellen auf Versuchstiere übertragbar? *Zentralbl. Bakt. I. Abt. Orig.* 118(1/2): 1-6. 1 fig. 1930.—Intracorneal injection of rabbits with contents of chickenpox pustules produced characteristic vesicles which were not produced by injection of material not containing specific varicella incitant.

1752. HAAGEN, E. Weitere Untersuchungen über das Verhalten des Variola-Vakzinevirus und des Herpesvirus in der Gewebekultur. *Zentralbl. Bakt. I. Abt. Orig.* 120(5/6): 304-310. 3 fig. 1931.—The author cultivated smallpox vaccine virus for over 2 yrs., through more than 100 testicular tissue passages, with distinct increase in virulence. Renal tissue also was well suited for protracted cultivation of the virus; typical Guarnieri inclusion bodies were seen in renal cultures of smallpox virus. Herpes virus (2 strains) maintained its keratotropic characteristics unchanged through 50-60 passages, but gradually lost its encephalotrophic properties.

1753. HODER, FRIEDRICH. Ein Agens, welches auf die Bakteriophagenvermehrung fördernd wirkt. *Zentralbl. Bakt. I. Abt. Orig.* 120(3/4): 162-165. 1931.—The author presents 8 experiments from which he concludes that substances exist in human and animal sera (and apparently also in certain bacterial species) which promote bacteriophagic action. Boiling for 5 min. does not destroy the substances, which he surmises are of vitamin-like or ferment-like character.

1754. IYENGAR, K. R. K., and W. A. BEER. Studies in the value of etherized sheep vaccine in the prophylactic treatment of rabies. Pt. 1. The effect of ether on "fixed virus" in infected brains of sheep. *Indian Jour. Med. Res.* 18(1): 1-4. 1930.—Resistance to ether of fixed virus in use at the Pasteur Institute, Coonoor, was tested by immersion of infected brains of sheep in the fluid, with the following results: (1) when the brain is cut into large pieces, 84-hr. immersion has no effect; (2) when cut into fine pieces and then suspended in ether, there is attenuation after 72 hrs. and death after 96 hrs.; (3) addition of 1% carbolic acid to 72-hr. ether brain and subsequent incubation at 37°C. for 24 hrs., kills the fixed virus.—*Authors' summary.*

1755. LEVADITI, C. Les ultravirus provocateurs des ectodermoses neurotropes. *Ann. Inst. Pasteur [Paris]* 45(6): 673-705. 23 fig. 1930.—The author uses the term "neurotropic ectodermatoses" to designate infectious diseases of the nervous system (like lethargic encephalitis, experimental herpes, poliomyelitis and rabies) produced by ultraviruses with elective affinities for tissues derived from the ectoderm, particularly its invaginated part, the neuraxis and its dependencies. The different neurotropic viruses have different affinities for various parts of the nervous system—the neurons, the astrocytes, the microglia and the oligodendroglia. Demyelinization may result from an ultravirus having an affinity for microglia (in which case the trouble is inflammatory and lipolytic) or from a disturbance of the lipoid metabolism of the oligodendroglia (in which case the oligodendrocytes merely retain and accumulate the lipoid products of their own metabolism).

1756. LÖTE, JOSEF v. Ueber einen Fall von rückfallender Tollwut (Lyssa recurrens) bei Kaninchen. *Zentralbl. Bakt. I. Abt. Orig.* 120(1/2): 86-89. 1931.—A rabbit (A) subdurally inoculated with brain substance from another rabbit which had died of typical rabies showed 2 temp. crises within 30 days. It survived inoculation for 210 days, meanwhile furnishing, on the 48th and 206th days after inoculation, pieces from the 2 parietal lobes for inoculation of 2 other rabbits, and dying in convulsions soon after the 2nd trepanation. The rabbit inoculated on the 48th day (B) died 18 days afterward of typical rabies. The one inoculated on the 206th day (C) died on the 114th day afterward, of characteristic rabies, the disease running a chronic course. A rabbit (D) inoculated immediately after the death of the original subject succumbed 140 days afterward to typical rabies, after running a very irregular temp. A rabbit inoculated with brain substance from rabbit B lived for 306 days, running an irregular temp., and died of scabies; Negri bodies were not found.

1757. MAZZETTI, GIUSEPPE. Osservazioni su di un ceppo di batteriofago isolato dalle acque luride di Siena. [Observations on a bacteriophage isolated from gutter waters in Siena.] *Boll. Soc. Ital. Biol. Sperim.* 5(4): 605-609. 1930.—A bacteriophage was isolated, which produced in vitro, both in liquid and in solid culture media, the phenomenon of Twort-d'Herelle.—*M. Comel.*

1758. MITCHELL, D. T. Rabies in Burma. *Union So. Africa Dept. Agric. Pan-African Agric. & Vet. Conf. Pretoria, Papers Vet. Sect.* P. 284-285. 1929(1930).

1759. OERSKOV, J. Nachweis und in vitro-Züchtung einiger vermutlich saprophytärer "Virusstämme." *Zentralbl. Bakt. I. Abt. Orig.* 120(5/6): 310-317. 2 fig. 1931.—Of this filtrable virus, living in close symbiosis with a motile, gram-negative, rod-shaped bacterium, 6 strains were isolated, 5 from milk and 1 from rabbit skin. The host bacterium was never found free from the virus. The virus formed characteristic, isolated, bacteria-free colonies if the substrate contained saccharose or raffinose and the host bacteria grew near by; it grew on saccharose agar in the neighborhood of bacteria killed by heat. By the Burri India ink method the virus appeared to be about ½ as large as is *B. pertussis*, and of ovoid coccus form. Reproduction seemed to be by transverse division. The cocci are not stainable with ordinary bacterial stains, but by other means can be rendered visible as tiny points of color. Their invisibility in uncolored preparations and in the dark field is apparently due to the fact that their index of refraction is about that of water. The virus withstands 1 hr. at 60°; the host bacterium, 50° for ½ hr.

1760. ØRSKOV, J., und K. A. JENSEN. Zur "Virusform" des Tuberkelbazillus. *Zeitschr. Tuberk.* 57(6): 398-404. 1 fig. 1930.—Of 70 guinea pigs inoculated with filtered material from 48 tuberculous patients only 1 died, 4 months later, from generalized tuberculosis.—*Authors' summary (transl. by W. Fornet).*

1761. PULCHER, CLAUDIO. Sull'adsorbimento del virus del sarcoma dei polli da parte dell'emoglobina. [Adsorption by hemoglobin of the virus of chicken sarcoma.] *Boll. Soc. Ital. Biol. Sperim.* 5(6): 888-891. 1930.—Electropositive, unlike electronegative, hemoglobin adsorbed much of the virus from the suspension fluid. The author concludes that the oncogenic virus of chicken sarcoma possesses a negative electric charge. —*M. Comel.*

1762. REMLINGER, P., et J. BAILLY. Unicité ou pluralité du virus rabique. [Unity or plurality of the virus of rabies.] *Ann. Inst. Pasteur [Paris]* 45(3): 376-385. 1930.

1763. SCHAEFER, WERNER. Über Herpesencephalitis bei Mäusen. (Zugleich ein Beitrag zur Frage der Erregerpersistenz im Zentralnervensystem.) *Zeitschr. Hyg. u. Infektionskr.* 111(4): 536-541. 2 fig. 1930.—A chronic herpetic encephalitis was produced in mice; 45 of 60 intracranially injected mice died, the majority on the 3rd and 4th days. Following intra-peritoneal vaccination, 32 of 40 died, the majority on the 6th to the 8th days. Surviving mice were killed 2, 4 and 10 weeks afterward. Inoculation of rabbits failed to show an inac-

tive persistence of herpes virus in the brain of mice.—*W. F. Jacobs.*

1764. **STEWART, FRED W., and C. P. RHOADS.** Lesions in nasal mucous membranes of monkeys with acute poliomyelitis. *Proc. Soc. Exp. Biol. & Med.* 26 (8): 664-665. 1929.—Preliminary paper.

1765. **TARANTELLI, EUGENIO.** Sulla presenza di elementi filtrabili (ultravirus) del b. di Koch nella tubercolosi cutanea e nel lupus eritematoso. [Presence of filterable elements (ultravirus) of the tubercle bacillus in cutaneous tuberculosis and lupus erythematosus.] *Arch. Ital. Dermatol., Sifil. e Venereol.* 6(1): 79-99. 1930.—Filtrates of skin tissue from 1 case of tuberculosis verrucosa and 6 cases of lupus vulgaris were inoculated into 14 guinea pigs; their ganglia and spleen were used to inoculate 7 guinea pigs, while 2 others were inoculated with spleen and ganglia of the 7; of these, 6 (4 directly inoculated and 2 of the 1st passage) died without appreciable cause in 10 days to 3 mos.; the others were killed in 1½-8 mos. Filtrate from the skin of 2 lupus erythematosus patients was inoculated into 4 guinea pigs; their spleen and ganglia were inoculated into 2 others, the spleen and ganglia of which were used to inoculate 1 guinea pig; of these 1 died; the other 6 were killed in 1½-6 mos. The clinical and histologic pictures were not distinguishable from those seen in normal animals; bacteriologic findings and tuberculin reactions were negative; 2 of 16 Besredka reactions and 1 of 17 Vernes resorcin reactions were positive. Results are inconclusive as to existence of ultravirus in cutaneous tissues affected with tuberculosis.

1766. **TARANTELLI, EUGENIO.** Ricerche su cavie non inoculate con filtrato di organi tbc. [Studies on guinea pigs not inoculated with filtrate of tuberculous organs.] *Arch. Ital. Dermatol., Sifil. e Venereol.* 6(5): 437-441. 1931.—In 8 of 15 supposedly normal guinea pigs, macroscopic changes were found in ganglia and spleen like those seen in pigs inoculated with tuberculous filtrates, with hypertrophy of peribronchial ganglia, splenic follicular hyperplasia and slight stimulation of the splenic reticulo-endothelial system, and presence of lymphocyte foci in the distal part of the lungs and agglomerations of well-preserved lymphocytes around the vessels and bronchi.

1767. **TEVELI, ZOLTÁN.** Die bazilläre Diagnose des Typhus abdominalis mittels Bakteriophagen. *Jahrb. Kinderheilk.* 130(1/2): 113-116. 1930.—Drops of Sonnenschein's bacteriophage were added to agar plate cultures of 11 old and 24 new strains of *Bacillus typhi*, as well as to cultures of 72 related strains. 3 strains of *B. typhi* and all the 72 related strains resisted the action of the bacteriophage, even when its virulence was increased by culture. Sonnenschein's diagnostic typhoid bacteriophage is thus specific and will identify typhoid bacilli, but is without effect on some 8% of strains. A strain giving a negative result should be examined further.

1768. **TWORT, FREDERICK WILLIAM.** Filter-passing transmissible bacteriolytic agents (bacteriophage). *Lancet* 219(5594): 1064-1067. 1930.—A restatement of the author's opinions, with no experimental work given.

1769. **VOSS, J. A.** Twort d'Herelle's phenomenon. *Acta Path. et Microbiol. Scandinavica Suppl.* 5: 49-52. 1 fig. 1930.—Observations are recorded, which seem to indicate that the Twort and d'Herelle phenomena are fundamentally identical and that the differences are due to the virulence of the bacteriophage and the resistance of the bacterium.

1770. **ANONYMOUS.** African conference of the yellow fever (Dakar, April 1928). 299p. 3 pl. L. Fournier: Paris, 1929. Price 42 fr.

LOWER ANIMALS

1771. **ARMSTRONG, CHARLES, G. W. McCOY, and SARA E. BRANHAM.** Filterability of the infective agent of psittacosis in birds. [*U. S.*] *Public Health Repts.* 45 (14): 725-726. 1930.—Organ emulsions of a parakeet sick from inoculation with organ emulsion of a parrot regarded as responsible for human infection, and emulsions of feces of a parrot also considered responsible for human infection, filtered through Berkefeld N filters and injected into parakeets, were as infectious as unfiltered emulsions.

1772. **DOYLE, T. M.** Fowl pox. *Eleventh Internat. Vet. Congress.* 3: 675-688. 1930(1931).—Agents other than the specific virus do not produce lesions clinically indistinguishable from those of fowl-pox. There is no evidence that bacteria alone can produce typical false membranes in fowls, although they may be of secondary importance. Although a filter-passing virus, that of fowl-pox passes through porcelain filters with difficulty. Infection almost invariably results from direct contact in cage experiments, but when healthy and infected fowls were placed in separate cages, facing each other, but a distance of 18 inches apart, infection did not occur. Neither did infection result when cages were placed in direct contact, but with the birds separated by a finely perforated metal sheet. The natural method of propagation is probably through wound infection. Apparently, "recovered" birds do not act as carriers. The viruses of fowl-pox and pigeon-pox are immunologically indistinguishable, yet they are in some respects, probably as a result of species adaptation, sharply differentiated. Cross immunity tests proved that fowl-pox does not immunize against cow-pox, nor vice versa. Dead virus confers no protection; if modified or attenuated by either physical or chemical means, it gives such inconstant results as to be of little practical value. Circumstances may sometimes justify use of live virus, but it is often followed by severe constitutional disturbance, and results obtained are in general too unreliable to justify it. Fowls inoculated with pigeon-pox virus are solidly immunized against severe natural infection, and partially protected against artificial infection with fowl-pox virus. Immunity is established about the 14th day after inoculation. The vaccine gives rise to no disturbances, and when employed in conjunction with hygienic measures, it should bring about a rapid and marked reduction in incidence of the disease.—*T. M. Doyle.*

1773. **DU TOIT, P. J.** Rabies in South Africa. *Union So. Africa Dept. Agric. Pan-African Agric. & Vet. Conf. Pretoria, Papers Vet. Sect.* P. 272-284. 1929(1930).—Since 1916 a number of human cases have been observed, which, clinically, appeared to be typical rabies. Recently 2 further cases occurred in boys who had been bitten by a yellow mongoose (*Cynictus penicillata*). Rabies was also diagnosed in yellow mongoose caught on the veld. Cases are recorded of a dog and an ox which contracted rabies, apparently from bites by infected yellow mongoose. Rabies has further been diagnosed in a genet cat (*Genetta felina*); and cases are recorded in man after being bitten or scratched by this animal. There is no evidence to show that other wild animals in So. Africa harbor rabies. The infected area appears to stretch from the eastern Transvaal to Bechuanaland (Vryburg) in the west and to the northern Cape (De Aar) in the south. The most remarkable feature about the disease in So. Africa is that it has not spread among dogs. The question arises as to whether it is true rabies. Apparently the infection has become somewhat modified during its sojourn in the wild carnivores. The origin of the present infection is unknown, neither is it certain how long the disease has been present; its control presents unusual difficulties. Eradication of the yellow mongoose and genet cat is practically impossible; but their numbers should be reduced. In the infected areas the number of dogs should also be restricted.—*From author's summary.*

1774. **GORI, PIO.** Ricerche sul virus dell'affezione difterto-vaiuolosa del piccione. [Virus of diphtheria-pox in pigeons.] *Lo Sperimentale* 84(2/3): 91-97. 2 pl. 1930.—In pigeons with avian diphtheria, scarification of skin provokes cutaneous manifestations of fowl-pox. Inoculation of pigeons with material from diphtheritic lesions produced fowl-pox, and vice versa. The authors believe that the virus of avian diphtheria and of fowl-pox is a

single entity, producing different types of lesions depending on the tissue affected.—*Maud L. Menten.*

1775. GREEN, R. G. Epizootic encephalitis of foxes. II. General consideration of fur-range epizootics. *Amer. Jour. Hyg.* 13(1): 201-223. 1931.—From a study of conditions on fur ranges in Wisconsin, where foxes are bred in captivity and where epizootic encephalitis has been present since 1923, it appears that fox encephalitis, with a slow rate of spread, may be present endemically among foxes in pens. When groups are run together in fur ranges, the disease increases to a violent epizootic. Any large group of apparently healthy foxes from an enzootic focus appears to develop an epizootic, indicating that carriers are common. The epizootic may appear in 4-6 days after common exposure and reach a peak in 2-3 wks. Mortality in foxes less than 10 mos. old is about 2½ times greater than that in foxes over 1½ yrs. old. Mortality in young foxes appears to average 12.5% of the population when based on known losses; it becomes 18.5% when approximated to include mutilated and missing foxes. The corresponding mortality for adult foxes is 3.5 and 8.5%, respectively. Individual ranch group mortalities as high as 40% of the group population occur. In several groups studied, having common ancestors, susceptibility appeared uniform. Significant variations in mortality of whole range groups and of ranch groups in the same range epizootic occur. Apparently, rapid variations in virulence occur.

1776. JACOTOT, H. Sur la teneur en virus de quelques tissus des veaux atteints de peste bovine expérimentale. *Bull. Soc. Path. Exotique* 24(1): 21-26. 1931.—Of about 17 tissues studied, with specimens from 1-6 animals for each tissue (including blood, spleen, lymphatic glands, tonsils, lungs, liver, kidneys, thymus, and various mucosae), the mucosa of the abomasum was found richest in virulent units.

1777. JACOTOT, H. L'infection pestique qui entraîne l'avortement peut-elle être propagée par le foetus et par la femelle qui l'a expulsé? *Bull. Soc. Path. Exotique* 24(2): 74-76. 1931.—In 2 of 17 cases of abortion from bovine plague (rinderpest), blood from the fetus proved clearly infectious; in 1 of 3 cases, the genital excreta of cows which had aborted conveyed infection.

1778. McBRYDE, C. N., W. B. NILES, and C. G. COLE. Experiments to determine the effect of sodium hydroxid and calcium hydroxid on the virus of hog cholera. *Jour. Amer. Vet. Med. Assoc.* 32(1): 87-89. 1931.—Tests showed that 3% NaOH plus 2% milk of lime is effective in destroying hog cholera virus in virulent blood within 15 min.

1779. McKINLEY, EARL B. The filterable viruses. *Scientific Monthly* 32(5): 398-403. 1931.—A review of the enlarging field of filterable viruses.

1780. METTAM, R. W. M. Contagious pleuro-pneumonia of goats in East Africa. *Union So. Africa Dept. Agric. Pan-African Agric. & Vet. Conf. Pretoria, Papers Vet. Sect.* P. 173-178. 1929(1930).—Contagious pleuro-pneumonia of goats is a specific caprine disease which ravages native and imported breeds annually, with a mortality of 60-100%. There appears to be a periodic variation in the potency of the virus. The disease may be acute or chronic and, especially in the chronic form, is frequently accompanied by a troublesome enteritis. The disease is due to a filter-passing virus which is present in lung lesions and in pleural effusions of acute cases. It has been successfully reproduced by intrabronchial insufflation, by intrapulmonary inoculation, and by contact with natural, acute cases. The disease causes highest mortality during the wet season. Both native and imported breeds are very susceptible. Recovery confers no immunity; relapses are very common. —*From author's summary.*

1781. POOL, W. A., A. BROWNLEE, and D. R. WILSON. The etiology of "louping-ill." *Jour. Comp. Path. & Therap.* 43(4): 253-290. 1930.—"Louping-ill" was produced experimentally in sheep and pigs. No evidence was found of a bacterial etiology. Infection does not occur from contact. An infective agent is present in certain tissues of affected sheep. At some stages this agent is probably constantly present in the central nervous system, and usually, but not constantly, in the mesenteric and popliteal lymph glands and spleen. It is usually present in the blood at some stage, but may be absent throughout. It was not demonstrated in cerebrospinal fluid, aqueous humor, bone marrow, liver, or skin. Infection was produced by intracerebral, intraspinal, intrasciatic, intra-ocular, intravenous and subcutaneous inoculation, and by supra-ocular instillation. It was not produced by intramuscular, intradermal, or endermic inoculation, by intranasal instillation, or by oral administration. Filtration experiments have not been completed; most of the experiments now reported yielded negative results. The infective agent is viable in 50% glycerol for at least 82 days. It resisted exposure for 3 hrs. at 20° C. to 1% phenol, 0.005% NaOH, and 0.001% $CuSO_4$. It resisted exposure for 1 min. at 60°, and was destroyed at 5 min. The study has not shown animals other than sheep or pigs to be susceptible.—*Authors' conclusions.*

1782. RICE, JOHN P. Avian diphtheritic enteritis and swine fever. *Vet. Jour. [London]* 87(1): 39-42. 2 fig. 1931.—The author believes that he has experimentally passed the avian virus to pigs, producing a typical swine fever. Such evolution is capable of explanation on the ground that the viruses are merely variants of a parent type, which have adapted themselves to certain species of animals, differences in tissue composition determining the differences in lesions produced.

1783. WALKER, J. Pleuro-pneumonia contagiosa bovum. Union So. Africa Dept. Agric. Pan-African Agric. & Vet. Conf. Pretoria, Papers Vet. Sect. P. 123-144. 1929 (1930).—A review of this disease, with bibliography.

MEDICAL

JAMES S. SIMMONS, *Editor*

(See also in this issue Entries 269, 274, 584, 1349, 1358, 1370, 1487, 1492, 1510, 1594, 1693, 1760, 1765, 1766, 1767, 1770, 1795, 1835, 2018)

1784. AARS, CHARLES G. Piedra. *Arch. Dermatol. & Syphilol.* 22(3): 401-409. 9 fig. 1930.—A description of piedra is given, based on 60 cases observed in Dutch Guiana. The condition is frequently met with in Paramaribo; it occurs in men more often than in women. The fungus is not a true ectothrix; in many cases, the cuticle of the hair was damaged by the parasite. In the dark nodules, perithecia are present, with asci containing 8 fusiform spores; probably, the perithecia are not provided with orifices. Pycnidia could not be observed. The ascospores consist of 1 cell and are provided with 2 (seldom 3) filiform ends. Cultures of the type, Rabello-Horta, never those of Juhel-Rénoy, were obtained. In hanging drop cultures, the fusiform spores never give rise to mycelium. Very old cultures show chlamydospore formation. Infection by bathing in river water could not be proved. The disease involves only the shaft of the hair. Pathogenicity is slight. The fungus probably belongs to the Perisporiaceae. In the cases observed, there is a great resemblance to Brazilian and Paraguayan piedra.—*Author's comment & conclusions.*

1785. CASTELLANI, ALDO. A mannitol fermenting

Monilia. *Proc. Soc. Exp. Biol. & Med.* 26(7): 544-545. 1929.—*Monilia* mannitofermentans (p. 545) is described from sputum obtained in chronic bronchitis.

1786. **ECKSTEIN, A. Epidemische Meningitis serosa.** *Zeitschr. Kinderheilk.* 50(5): 564-595. 11 fig., 1 map. 1931.—Between May and Nov., 13 cases (2 in sisters, 2 in children in same class) were observed in Düsseldorf; all children recovered. In 1 case, inoculation of a monkey with cerebrospinal fluid from a girl with a recurrence induced the disease. Inoculation from 2 other cases was unsuccessful. In so far as it is not a disease entity, the author would group epidemic meningitis serosa with meningeal encephalitis.

1787. **GARCÍA, CAMILO LÓPEZ. Diagnóstico bacteriológico precoz de la difteria por médio de cultivos. II. [Early diagnosis of diphtheria by cultures.]** *Quinta Reunión Soc. Argentina Patol. Reg. Norte* 1: 383-390. 1 pl. 1930.—Pergola's medium was found to afford the earliest cultural diagnosis of diphtheria from suspected patients, colonies showing a well marked characterization in 18-20 hrs. By early observation of cultures, 100% of positive results was reached for cases of true diphtheria, while negative results were mainly obtained from carriers. The method proved to be quite unreliable for detecting healthy carriers.—*Author's conclusions (transl. by A. de Assis).*

1788. **[ĬARYSHEVA, K.]** ЯРЫШЕВА, К. О поверхностной трихофитии гладкой кожи. **[Superficial trichophytosis.]** [With English summary.] Одесский Медицинский Журнал *(Odessaer Med. Zeitschr.)* 4(8/10): 505-521. 3 fig. 1929.—The author describes in detail 4 cases; 3 of them had hair and nails also affected. Microscopic investigation revealed *Trichophyton megalosporon ectotrix.* In one case, where nails and scalp were intact, hematogenic origin is possible. In the other 3, the origin is difficult to determine.—*B. Van Rosen.*

1789. **MAFFEI, LUIGI. Nuova specie di Cephalosporium causa di una cheratomicosi dell'uomo. [A new species of Cephalosporium causing keratomycosis in man.]** *Atti. Ist. Bot. "Giovanni Briosi" e Lab. Crittogam. Italiano Univ. Pavia* 1: 183-198. 9 fig. 1929(1930).—At the hospital in Parma, Serra isolated from the eye of a 35-yr.-old farmer, a *Cephalosporium* which caused keratomycosis. It is the first time any species of this genus has been found in ocular mycoses. As a tribute to the discoverer, the organism is here named *C.* **serrae.** —*L. Maffei (transl. by P. Hillkowitz).*

1790. **MEYER, KURT, und EDMUND MAYER. Kolbenkranzbildung um tote Tuberkelbacillen als Reaktion des Wirtsorganismus. Ein Beitrag zur Genese der Actinomycesformen.** *Zeitschr. Hyg. u. Infektionskr.* 108(1): 38-53. 6 col. fig. 1927.—"Ray fungus" forms with clubbed filaments can be produced in rabbits by injection of killed tubercle bacilli. Since the bacteria are dead, these must be a product of the host, rather than a stage in the life-cycle of the bacterium. Analogous responses occur to various irritants, such as actinomyces, actinobacilli, other acid-fast bacilli, staphylococci, and even to inorganic substances (tellurium). The club forms produced in actinomycosis are therefore to be explained as host reaction products.—*Authors' summary (transl. by R. C. Whitman).*

1797. **GILL, CLIFFORD ALLCHIN. The genesis of epidemics.** xxvi+550p. 10 maps. Baillière, Tindall and Cox: London, 1928. Pr. 21s.—This volume constitutes a thoughtful and absorbing approach to a study of the genesis of epidemics. It is nominally a monograph on the author's "quatum" theory; in reality it is an approximation to a re-formulation of the essential variables (and their inter-relations) in the causation and cessation of epidemics of malaria, influenza and plague. The essential matter in the analysis is that the infection and immunity phases of epidemic disease each involve at least several important variables. The quantitative aspect is largely undeveloped in this treatise, for the same reason that commonly applies,—lack of precise data. There is a modicum of quantitative information upon each of several variables; but there is almost no precise knowledge on the functional relations or inter-relations of the several variables.—*I. S. Falk.*

1800. **PHILIP, CORNELIUS B. Possibility of mechanical transmission by insects in experimental yellow fever.** *Ann. Trop. Med. & Parasitol.* 24(4): 493-501. 1930.—

Negative results were reported in 3 attempts to transmit yellow fever to monkeys by interrupted feeding of 39 to at least 100 *Aedes aegypti* mosquitoes, and in 1 effort involving bed-bugs in the larval, nymphal, and adult stages. 3 infections (2 fatal) were produced by injection of lice (*Pediculus* sp.) taken from infected monkeys, but tests by biting were not accomplished. The improbability of mechanical transfer of the virus by regurgitation during interrupted feeding of these insects is discussed and the conclusion is reached that yellow fever epidemics are not aggravated by mechanical transfer through intermittent feeding of such insects.—*C. B. Philip.*

1801. **RAJU, V. GOVINDA.** Bacterial efficiency of mechanical gravity filters. *Indian Jour. Med. Res. Calcutta* 14(3): 707-712. 1927.—Study of the relation of the bacterial count in influent to the count in effluent water in 24 gravity filters, of 3 different types, over a period of 2 yrs. It was found that in over 75% of the tests the ratio of bacteria in feed water to filtered water was 10: 1.—*B. H. Robbins.*

1802. **SIMPSON, WALTER M.** Recent developments in tularemia, Francis' disease. *Jour. Lab. & Clin. Med.* 15(4): 311-322. 2 fig. 1930.—Tularemia, until recently regarded as confined to the U. S. A. and rarely reported in man, has recently been found to be world-wide. It is identical with Ohara's disease in Japan, and appears to be widespread in Russia; 800 proved cases have been recognized in the U. S. A. Among the animal hosts discovered, besides rabbits, are European water rats or voles (*Arvicola amphibius*), in Russia; meadow mice (*Microtus californicus aestuarinus*), in Contra Costa County, California; sheep (*Ovis aries*) and muskrats (*Ondatra zibethica*), in Montana; opossums (*Didelphis virginiana*), in Florida; woodchucks or ground hogs (*Marmota flaviventer*) in Ohio and Arkansas; and quails or bobwhites (*Colinus virginianus*). Among the insect hosts are deer flies (*Chrysops discalis*), rabbit ticks (*Hemaphysalis leporis-palustris*), wood-ticks (*Dermacentor andersoni* Stiles, *D. occidentalis* Newman), and another tick thought to be *D. variabilis*. The author reports 11 new cases.

1803. **TRAWIŃSKI, A.** Études sur la vitalité des bacilles pathogènes du groupe coli-typhique dans l'eau de mer. *Bull. Inst. Oceanogr.* [*Monaco*] 1929(542): 1-5. 1929.—The viability of organisms inoculated into water taken from the "open sea" and into sewage contaminated sea water was as follows (the 1st figure refers to viability in uncontaminated sea water; the 2nd, to sewage contaminated water): *B. paratyphosus B*, 12-12 days; *B. paratyphosus* Breslau, 21-7 days; *B. paratyphosus* Gaustedt, 16-16 days; Gaertner bacillus, 23-5 days; *B. paratyphosus A*, 18-6 days; *B. typhosus*, 16-3 days; *B. dysenteriae* Shiga, 12-30 hours.—*N. M. Erb.*

1804. **BAAS-BECKING, L. G. M.** Historical notes on salt and salt manufacture. *Scientific Monthly.* 32(5): 434-446. 4 fig. 1931.—Very ancient methods of salt manufacture are still in use. Manufacture by boiling is described in Chinese documents dating to 2200-2500 B. C. The red color common in salt marshes, in salt, and in brines, is discussed. It may be due to iron oxid; (possibly) metallic Na; pink, red, or purple bacteria; red yeasts; flagellates (*Dunaliella salina*, etc.); and, probably, blue green algae (*Aphanocapsa*). Purification methods are discussed, and particularly the rôle of the "clearer-worm," *Artemia salina*. Brine, salt-marsh, and salt-works biota are world-wide in distribution. *A. salina*, in Arabian lakes, is eaten by the natives; it has probably been used in the purification of salt since very early times.

1805. [**BAKHTIN, V. S.**] БАХТИН, В. С. Грибные вредители книг. [**Fungi harmful to books.**] Дневник Всесоюзного Съезда Ботаников, Ленинград (*Jour. All-Russ. Congr. Bot., Leningrad*) 1928: 169-170. 1928.—Abstract. A list of fungi found attacking books of a Russian public library is given; 50 are different spp. of *Stachybotrys*. Methods for preservation of the books are given.—*G. A. Lebedeff.*

1806. **CORBET, A. S.** A preliminary study of the bacteriology of Hevea latex. *Rubber Res. Inst. Malaya Quart. Jour.* 2(3): 139-155. 1930.—Microorganisms isolated from the latex of *Hevea brasiliensis* are described. Of these, *Bacillus pandora* and *Micrococcus* **epimetheus** (p. 148) are of interest in that both produce acid in latex and the latter is also responsible for gas formation. The bearing of these organisms on the process of natural coagulation is discussed. *Micrococcus* **chersonesia** (p. 150) is dimorphic, occurring in 2 colony forms associated with differences in morphology. 3 species produce yellow pigments with latex, but as the colored substances are soluble in water they are largely removed during the preparation process. The following are also described: *Gaffkya* **verneti** (p. 143); *Micrococcus* **eatoni** (p. 145), *M.* **ridleyi** (p. 146); *Alcaligenes* **denieri** (p. 152); and *Torula* **heveae** (p. 153).

1807. **IRISH, J. H., and M. A. JOSLYN.** The viability of yeast. The effect of freezing storage in grape juice. *Fruit Products Jour. & Amer. Vinegar Indust.* 8(12): 11. 1929.—Up to 18 weeks, freezing storage apparently does not affect the viability of yeast in grape juice.—*J. A. Kennedy.*

1808. **LAKOWITZ.** Der Teepilz und der Teekwass. *Ber. Westpreuss. Bot. Zool. Verein.* (*Jubiläum*) 50: 77-84. 1928.—The "tea fungus" is a symbiotic association of *Schizosaccharomyces pombe* and *Bacterium xylinum*. Other yeasts, e.g., *Saccharomycodes ludwigii*, *S. exiguus*, and *S. apiculatus*, are also present. With this fungous community a beverage ("teekwass") can be obtained by addition of sugar and a little lemon juice to ordinary tea infusion. It is very refreshing and contains, aside from aromatic substances, acetic and lactic acids. It is very effective against constipation. The fungus, which develops rapidly in culture, has been kept for 2 yrs. On account of the acids formed, metal containers should not be used. The fungus was introduced from the Far East.—*Lakowitz* (*transl. by F. Weiss*).

1809. **SELIBER, G.** Die Wirkung verschiedener Toluolmengen auf die Vergärung von Zucker durch frische und getrocknete Hefe. *Biochem. Zeitschr.* 224 (1/3): 202-210. 1930.—Over 30 series of experiments indicate that toluol (2-40%) has no special influence on retardation of fermentation by living yeast. Living yeasts show in the presence of toluol an intensity of 10-50% in comparison to the same yeast without toluol; a more marked effect is obtained by trituration with toluol. Dry yeast is more sensitive to toluol, especially after long continued fermentation; only in severely dried yeasts a slight difference can be noted between yeast action with or without toluol.—*G. G. De Bord.*

1810. **SIMON, ERNST.** Ueber das zymatische System und die Wirkungen der Essigbakterien. *Biochem. Zeitschr.* 224(4/6): 253-291. 1930.—Using resting cells and acetone-dry preparations of 2 organisms of the *Acetobacter* group, *Bact. pasteurianum* and *Acetobacter suboxydans*, the author finds that the enzyme system of the acetic acid bacteria includes carboxylase, ketone-aldehyde mutase, phosphatase, and glycolase. Glucose yields alcohol and CO_2; hexose diphosphate yields methyl glyoxal; methyl glyoxal yields l-lactic acid; pyruvic acid yields CO_2 and acetaldehyde; acetaldehyde yields

alcohol and acetic acid in equimolecular proportions under anaerobic conditions. Under aerobic conditions but little alcohol is formed. Alcohol yields acetic acid under aerobic conditions.

1811. **TAKETOMI, N., and S. HANAMURA. The cause of the low yield of alcohol in the fermentation of Formosan cane molasses. (1st report.)** Original: *Jour. Soc. Chem. Ind. Japan* 30: 390-395. 1927; Abridgement: *Mem. Fac. Sci. & Engineer. Waseda Univ., Tokyo* 7: 129. 1930.—Usually, alcohol yields of 80-83% of the theoretical have been obtained. Addition of 0.1 gm. ammonium sulphate or phosphate per 100 cc. of liquid to be fermented, increased the alcohol yield to 97-98% of the theoretical. NH_4 salts are thought to function as a food for the yeast, N probably being insufficient in the molasses.—*From abridgement.*

1812. **THAYSEN, A. C., and L. D. GALLOWAY. The microbiology of starch and sugars.** 336p. 3 fig. Oxford University Press; Humphrey Milford: London, 1930. Price $8.50.—This is a complementary volume to Thaysen and Bunker's "Microbiology of cellulose, hemicelluloses, pectin and gums," the 2 volumes giving a review of the microbiology of the carbohydrates. It is written from the point of view of the research worker, and, in addition to compiling existing knowledge, points out new paths for investigation. Pt. I considers the constitution and biochemical properties of starch, glycogen and inulin; their microbiological hydrolysis; hydrolysis of tetra-, tri-, and disaccharides; and hydrolysis of glucosides. Pt. II. takes up fermentation of monoses; dehydrogenation of hexoses resulting in production of gluconic, saccharic, succinic, fumaric, oxalic and citric acids; aerobic dehydrogenation of hexoses resulting in formation of acetic and formic acids, acetylmethylcarbinol, and 2:3 butyleneglycol; facultative anaerobic dehydrogenation of hexoses resulting in acetic acid, formic acid, ethyl alcohol, acetylmethylcarbinol and 2:3 butyleneglycol; facultative anaerobic dehydrogenation of hexoses involving formation of lactic acid as an essential decomposition product by: (1) The *Bact. coli commune* and *Bact. lactis aerogenes* groups, (2) the lactic acid bacteria, and (3) the propionic acid bacteria; the obligatory anaerobic dehydrogenation of hexoses; and fermentation of pentoses. Pt. III covers the synthetic activities of microorganisms and the mucus fermentations. Pt. IV considers the microbiology of cereals and cereal products; of grain and its milling products—bran and flour; of starch-containing sizing materials and adhesives; microbiology of baking; and diseases of bread. Pt. V considers the microbiology of sugar-cane and sugar-beet, and their raw juices; of cane juice and beet juice in manufacture; and the microbiological deterioration of sugar in storage. The subjects are covered completely, both as regards organisms and biochemical processes. The working theory adopted in Pt. II for grouping the various microbiological fermentations is that of Kluyver and Donker, based on Wieland's theory of the chemistry of respiration. About 800 references and an author and subject index are included.—*M. W. Jennison.*

1813. **WERKMAN, C. H., R. M. HIXON, E. I. FULMER, and C. H. RAYBURN. The production of propionic acid from pentoses by Propionibacterium pentosaceum.** *Proc. Iowa Acad. Sci.* 36: 111-112. 1929(1931).—Both propionic and acetic acids are produced from xylose and arabinose.—*H. S. Conard.*

1814. **WILLAMAN, J. J., and Z. I. KERTESZ. The enzymic clarification of grape juice.** *New York State [Geneva] Agric. Exp. Sta. Tech. Bull.* 178: 1-15. 1931.—The objectionable turbidity of grape juice, due to colloids, can not be removed by ordinary filtration methods. A new method, here described, is applicable to grape juice and other fruit and vegetable juices. Molds grown on appropriate media produce an enzyme which converts most of the pectin of grape juice into other soluble substances. A portion of the pectin comes down as a flocculent precipitate which occludes other suspended matter. By simple filtration this precipitate is removed, leaving a brilliantly clear juice. Production of the enzyme from *Penicillium glaucum* and practical use of the process is described in detail.—*J. J. Willaman and Z. I. Kertesz.*

1815. **WINDISCH, FRITZ. Über den Gärungs-Vorgang auf dem Bottich.** *Wochenschr. Brauerei* 46(38): 379-388. 1929.—Several 10-liter vats were inoculated with the same quantities of yeast, 2 races being used. Each day, for 8 days, a vat was withdrawn and determinations were made of pH, amount of substrate fermented, and distribution of cells deposited and in suspension. With both races, the number of cells in suspension reached a marked maximum on the 4th day, rapidly decreasing thereafter. The number of cells sedimented increased gradually throughout fermentation. The sedimented yeast consistently showed greater reproductive and fermentative action than the suspended cells. These findings are not in harmony with the accepted views on bottom fermentation.—*E. I. Fulmer.*

1823. MACY, H. Quantitative changes in the microflora of butter during storage. *Jour. Dairy Sci.* 13(3): 266-272. 1930.—From a study of 483 samples of commercial salted and 123 of unsalted butter before and after storage at various temp. and periods of time, it was found that salt retards multiplication of molds, yeasts and bacteria. The author concludes that the ratio of increase is higher in unsalted than in salted butter, while the opposite is true for the ratio of decrease. It was also found that salt content has a decided effect on quantitative changes in the microflora during storage, but that this is not in proportion to amount of salt present.—*D. B. Shutt.*

1824. RENNES, M. Examen et analyse du lait, physique, chimique, biologique. 118p. Published by the author: 29 rue Mademoiselle, Versailles, 1930. Price 12 fr.

1825. VIRTANEN, ARTTURI I., und H. KARSTRÖM. Über die Milchsäuregärung. V. *Hoppe-Seyler's Zeitschr. Physiol. Chem.* 174(1/2): 1-27. 3 fig. 1928.—Dried preparations of *B. casei* ε cause lactic acid fermentation of glucose independently of living cells. Although toluol causes complete disappearance of living cells in 1.5 hrs., fermentation continues for over 20 hrs. In absence of antiseptics, 100 million normal living cells ferment 2.7 mg. glucose, whereas only 0.1 mg. glucose is fermented by the same number of dried cells. Dried preparations of *Strep. lactis* and *B. delbrückii* become practically inert in presence of toluol. The effect of pH on the fermenting action of living and dried bacteria (*B. casei* ε) is shown in a graph; living cells have a lower limit of ± 2.3, which rises gradually to an optimum of 6.2, and then gradually drops to 9.4; dried cells have a lower limit of 4.7, which rises sharply to 5.8-6.1, and then sharply drops to 7.0. Thus, the less active the preparation the more sensitive it becomes to pH changes. The optimum PO_4 concentration for living cells is 0.14 M; for dried cells it is 0.5 M. To extract cozymase, 6-8 gm. of dried preparation are thoroughly mixed in a mortar, previously warmed to 45°, with 200 cc. of distilled water and then centrifuged. The operation is repeated thrice. Sometimes a more active cozymase is obtained by extracting with a 0.25 M phosphate solution. By determining the glucose, lactic acid and phosphoric acid at intervals, it was found that fermentation takes place in 2 phases: in the 1st phase, 50% of the glucose disappears, the combination of phosphate is very marked, but the lactic acid formation is minimal; in the 2nd phase, lactic acid formation is strong, the remainder of the glucose disappears and the phosphate is again gradually set free. Although there thus appears to be a stage of hexosephosphate combination followed by a 2nd stage in which the hexose-phosphate decomposes with formation of lactic acid, the process is nevertheless very complicated. Living *B. casei* ε form upwards of 90% lactic acid from glucose, but at the end of the reaction only 50% of the glucose can be accounted for as lactic acid. No more than the normal small quantities of volatile aliphatic acids, acetic acid and succinic acid are formed. Possibly part of the sugar is converted into a non-reducing hexosephosphate compound. It was shown that lactic acid is not destroyed by oxidation. Washed, dried preparations of *B. casei* ε can not be activated by insulin. A slight inhibitory effect was sometimes noted on lactic acid fermentation by insulin. Although lactic acid bacteria contain a substance which lowers blood-sugar, no relationship could be found between insulin and cozymase.—*F. A. Rotondaro.*

1827. CRANSTON, J. A., and B. LLOYD. Experiments on bacterial denitrification. *Jour. Roy. Tech. Coll. Glasgow* 2(2): 301-315. 6 fig. 1930.—Denitrification caused by a marine bacillus in a broth containing 0.25% KNO_3 was studied. The gas evolved was pure N. After an initial lag period, the rate of gas production decreased exponentially according to the equation: $V=2.8(1-e^{-1.38t})$, where V is the volume of gas produced in cc., and t is the time in hrs. In a nitrite-free medium, the organism produced a decrease in alkalinity from pH 8.8 to 8.0 in 2 days, and a subsequent increase to 8.8 after 20 days; in a nitrite broth, the pH changed from 8.8 to 8.5, with a subsequent change to 8.9 after denitrification began. Raising the temp. caused an increase in rate of denitrification, the rate being more than trebled when the temp. was raised from 26.5 to 31.9°C. When both nitrite and methylene blue were available, the former was reduced in preference to the latter.—*Authors' abstract.*

1828. DIXON, DOROTHY. The micro-organisms of the tertiary red sands near Melbourne, Victoria. *Australian Jour. Exp. Biol. & Med. Sci.* 7(4): 161-169. 1930.—Variations in numbers of microorganisms were influenced by changes in soil moisture and temp. in both the sandy and clay soils. Minimum counts were observed during cold and dry periods; maxima seemed to occur after rain, when the temp. was high enough. During 1929 the influence of the rise in temp. can be seen best, on account of the soil being constantly moist. Clay soil supported a greater number of soil fungi than sandy soil. After cultivation, the sandy soil showed a decrease in numbers of organisms; in the clay soil the reverse was the case. Of the genera isolated, 13 were common to both areas. Uncultivated soil showed fewer Phycomycetes but a greater number of species of *Penicillium, Aspergillus,* and *Trichoderma.*—*Author's summary.*

1829. LLOYD, B. Bacterial denitrification: an historical and critical survey. *Jour. Roy. Tech. Coll. Glasgow* 2(3): 530-550. 1931.—A historical and critical survey of bacterial denitrification is given under the following headings: mechanism, rate, conditions affecting it, and denitrifying species recorded in the literature. A detailed bibliography is appended.—*Author's summary.*

1830. [RAVICH-SHCHERBO, IŪ.] Равич-Щербо,Ю. К вопросу о бактериал'ной пленке в Черном море по гипотезе проф. Егунова. **(The problem of a thin bacterial layer in the Black Sea according to the hypothesis of Prof. Egunov.)** [With English summary.] Труды Севастопольской Биологической Станции Академии Наук СССР. (*Trav. Sta. Biol. Sébastopol*) 2: 127-141. 1930.—In a sea water aquarium with decayed organisms, a thin bacterial layer was observed at a depth of 50 cm. Chemical and microbiological tests

revealed the presence of great quantities of H_2S and a complete absence of O_2 under the bacterial zone. Above the bacterial layer great quantities of O_2 and the complete absence of H_2S were observed. *Thiobacillus thioparus* in the bacterial layer was found responsible for oxidation of H_2S. This explains the absence of H_2S above the bacterial layer, a phenomenon similar to that observed by Eganov in the Black Sea to a depth of 175-200 m.—*S. A. Corson.*

1831. SELIM, M. Nitrogen-fixing bacteria in soils. *Zentralbl. Bakt. II. Abt.* 83(15/22): 311-325. 1931.—N-fixing bacteria of 13 types were isolated from soils. The amount of N fixed in 100 cc. of glucose soil extract by different strains of each type were: *B. aerogenes,* 1.12-2.25 mgm.; *B. cloacae,* 0.99-1.56 mgm.; *B. radiobacter,* 0.42-0.75 mgm.; an *Alkaligenes* type, 0.58-0.61 mgm.; *Bact. lactis innocuum,* 0.61-0.64 mgm.; *Bact. prodigiosum,* 0.88 mgm.; *B. malabarensis,* 0.58-1.68 mgm.; *B. megatherium,* 2.41 mgm.; *B. saccharobutyricus,* 2.30 mgm.; *Azotobacter,* 1.75-2.07 mgm. Other strains of *B. cloacae, B. radiobacter* and *B. megatherium,* and also strains of *Bact. turcosum, Bact. punctatum* and *Micrococcus sulfureus,* were unable to fix N in glucose soil extract, but brought about a small fixation when sterile soil was added to the medium. Addition of soil to the medium also resulted in an increased fixation of N by most of the other organisms. The first 6 organisms appear to belong to a wide group of intergrading forms and many of them produced identical, slimy, raised colonies on mannite soil extract agar. Several of the bacteria partially or completely lost the ability to assimilate N during several months' growth on mannite soil extract agar. Cultivation in sterile soil for a few months had no influence on the N-fixing power of the bacteria studied. The N fixed by several of the pure cultures grown in association was determined. The highest fixation was obtained by a mixed culture of *Azotobacter* and *B. saccharobutyricus.* A number of soils of different origin, 2 ignited soils, certain Fe compounds and aluminium hydroxide exerted a small favorable effect on N fixation by *B. aerogenes* in glucose soil extract. Several strains of *B. radiobacter* produced a loss of N in the tests.—*M. Selim.*

1832. BOYD, ELDON M., and GUILFORD B. REED. Gas-metal electrode potentials in sterile culture media for bacteria. *Canadian Jour. Res.* 4(1): 54-68. 1931.—The work of French and Kahlenberg on gas-metal electrode potentials suggested that the potentials obtained at inert metal electrodes immersed in growing cultures of bacteria, and generally regarded as an oxidation-reduction phenomenon, might be of a similar type. This was tested by passing air, H, N and CO_2 through sterile beef broth and observing the potentials developed at Pt, Au, and Hg electrodes. It is shown that air causes a rise in potential at all 3 electrodes; H causes a marked fall in potential at the Pt and a slight change at the Au and Hg electrodes; N and CO_2 cause little or no change in the potential at the 3 electrodes. These changes are in agreement with French and Kahlenberg's results, except in the case of the Hg electrode, which is shown to react chemically with the broth.—*Authors' abstract.*

1833. CHURCHMAN, JOHN W. Non-toxic dyes and dye-resistant bacteria. *Stain Technol.* 6(2): 57-63. 7 fig. 1931.—Exposure of 3 typical organisms—*Serratia marcescens (Bacillus prodigiosus), Bacillus anthracis,* and *Staphylococcus aureus*—to a saturated aqueous solution of neutral red (5.6% National Aniline certified) for 24 hrs. failed to kill them, and *Serratia* survived 9 days' exposure. All 3 survived 21 days' exposure to 2% neutral red, and *B. anthracis,* 30 days. All 3 survived 24 hrs.' exposure to saturated aqueous Bismarck brown (Grübler) and *B. anthracis,* 40 days. *Serratia* (as a Gram-negative organism) was tested for degree of resistance to gentian violet. The bacteriostatic titer of gentian violet in agar for the organism is about 1: 900. *Serratia* survived 4 hrs.' exposure to 1: 2000 dilution, and would probably be unaffected by much stronger solutions. Vigorous growth of the organism was obtained after 26½ mo. at 1: 15,000 dilution, and after 16 months at a higher concentration (1 drop of 1% dye to 3 cc. bacterial suspension). With acid fuchsin, transplants from tubes containing 2 cc. bacterial suspension and 4 drops of 2% aqueous dye solution showed vigorous growth after 46 mo. exposure. Bactericidal action of both gentian violet and acid fuchsin is greatly increased by a slight rise in temp.—*Author (courtesy Wistar Bibl. Serv.).*

1834. FOREMAN, F. W., and G. S. GRAHAM SMITH. The control of reaction in cultures and enzymic digests. *Dept. Sci. & Indust. Res.* [*Great Brit.*] *Food Invest Spec. Rept.* 32: 1-27. 1928.—Data from 2 experiments previously published are the basis of a detailed discussion of the relations between fluctuations in pH and those in titrable acidity. Phosphates and creatinine were responsible for most of the buffering observed in meat extract between pH 9.0 and 4.0. The curves obtained were compared with $[H^+]$ curves for phosphate solutions of the same strength. The $[H^+]$ curve for the phosphate showed that successive unit increments of acid produce increasingly greater increments of increase in actual $[H^+]$ along the whole course of the changes from the all-salt to the all-acid stages and, on comparing with the pH curve, that $[H^+]$ is stabilized best where the ratio of salt to acid is highest and where the steepness of the pH curve shows the stabilization of pH to be nearly at its lowest. This observation led to a consideration and replotting of Sorensen's phosphate data and Walpole's curves for acetic acid-acetate mixtures. On comparing the pH and $[H^+]$ curves it is seen that in the early region, viz., that near the all-salt end, the steeper the pH curve the greater the resistance to change of $[H^+]$; while in the later region the steeper the pH curve the less the resistance to change of $[H^+]$. Further, at any 2 points on the early and late portions of the pH curve, where the slopes are the same and consequently the "buffering" capacities of the 2 solutions equal, there is a very great difference in capacities of the solutions to resist change of $[H^+]$. To avoid confusion, it seems desirable to use another term in reference to resistance to change of $[H^+]$. Having regard to the depressing action of the salt on the dissociation of the free acid illustrated in the "% dissociated" curves, the term "depressor effect" is employed. The authors suggest that media be stabilized against increase in $[H^+]$ by choosing a depressor salt whose maximum effect is at, or slightly to the alkaline side of, the desired reaction. The data of Van Slyke and Zacharias on the action of urease in urea solutions containing phosphate mixtures are reinterpreted according to this concept. It is concluded that there is sufficient justification for the view that the effects of salts on the activities of enzymes and bacteria in media should be considered from the standpoint of how these salts affect the absolute $[H^+]$ and $[OH^-]$, as well as from the standpoint of how they affect pH. In construction of artificial media these 2 standpoints involve 2 different ways of employing salts. —*A. G. Benton.*

1835. HAASE, W. Unsere Erfahrungen mit der Hohnschen Kultur. *Bruns' Beitr. Klin. Chir.* 151(2): 318-325. 1930.—Positive Hohn cultures were obtained in

45 of more than 500 specimens from clinical material; in 31 (14 from urine, 10 from abscesses, 5 from sputa, 1 from ascites, and 1 from prostatic secretion) tubercle bacilli could not be found in smears with Ziehl-Neelsen stain; 2 cultures were negative (1 pus, 1 urine), but with smears positive (perhaps acid-fast saprophytes, perhaps dead bacilli); 3 cultures were positive, with negative animal inoculations; 9, negative, with positive animal inoculations. The cultures were positive after an average of 21 days (frequently in 5 days); no attempt was made to diagnose questionable colonies early; cultures negative at 50 days were so designated. By a special method it was possible to stain the Hohn cultures for photographing.

1836. **HURIET, J. Observations sur les bactéries du groupe "subtilis-mesentericus-megatherium."** 20p. Pharmacie Huriet: Nancy, 1929.

1837. **KRISTENSEN, MARTIN. Klassifikation dänischer und anderer Brucellastämme.** *Zentralbl. Bakt. I. Abt. Orig.* 120(3/4): 179-196. 1931.—Agglutination and agglutination-absorption experiments [apparently on nearly 50 strains] showed no type distinction between strains of *Brucella abortus, Br. melitensis,* and the Danish swine type. The methyl-violet-thionin test and that based on H_2S formation appeared to give a good basis for classification of the group. By both these tests all Danish cattle and human strains gave the reactions described as characteristic for the bovine type. Danish swine strains by methyl-violet-thionin test showed closest relations with the American swine type, from which, however, they differed through lack of H_2S formation, etc.—*Author's summary (transl.).*

1838. **LOGHEM, J. J. van, en A. VEDDER. Een nieuwe type of een door den bacteriophaag versterkte eigenschap? [New bacterial type or intensified bacteriophagic property?]** *Nederlandsch Tijdschr. Hyg. Microbiol. en Serol.* 4(4): 251-254. 1930.

1839. **NYRÉN, TEOFILIP. Über die Einwirkung von Lipoidlösungen auf das Wachstum säurefester Bacillen.** *Beitr. Klin. Tuberk.* 73(2): 238-250. 1929.—The acid-fast strains studied included (I) true tubercle bacilli of warm-blooded animals (human, bovine, bovine Vallée, and BCG); (II) tubercle bacilli of cold-blooded animals (Friedmann's turtle tubercle bacilli, blind-worm tubercle bacilli); (III) saprophytes (water and timothy bacilli, etc). The lipoids studied were human, bovine, swine, vegetable and egg lecithins, and cholesterin from human brain. Of the 5 lecithins, all (but particularly, egg lecithin), in Much's cell-disperse solution, promoted growth of the strains of warm-blooded tubercle bacilli used. Cholesterin does not promote growth of these bacilli; whether it inhibits their growth is not established. Growth of cold-blooded tubercle bacilli and saprophytes is not inhibited by lecithins, except human lecithin which hinders growth of several saprophytes. Cholesterin is strongly inhibitory or fatal to growth of this group of acid-fasts. Addition of peptone to the 4% water-agar employed does not promote growth of the warm-blooded tubercle bacilli, but strongly promotes growth of the other acid-fasts. The acid-fast bacilli tested grow on lipoid media with strongly granulated forms, as shown by carbol-fuchsin staining. On many of these media acid-fast bacilli lose their acid-fastness. Cold-blooded tubercle bacilli grow on peptone media with strongly granulated forms. On the contrary, saprophytes (except 1 strain) grew on peptone as homogeneous rods.

1840. **PLOTZ, HARRY, et JEAN GELOSO. Relations entre la croissance des microorganismes anaérobies et le potentiel du milieu de culture.** *Ann. Inst. Pasteur [Paris]* 45(5): 613-640. 3 fig. 1930.—Measurements of potential, chiefly by the electrometric method, were made on the medium in which various anaerobes were grown. A new technique was used, which permits measurement of potentials in vacuo. During bacterial growth the potential varied, finally attaining a fixed value corresponding to $rH_2=5.5$. This value was independent of the original potential indicated by the electrode, of the method used to render the medium anaerobic, and of the species of bacterium grown. The potential of the non-inoculated bouillon was followed and gave the potential limit of glucides, $rH_2=7.5$ at 37°. Potential curves analogous to those observed with cultures were obtained by use of a liberal quantity of platinum black in the bouillon; this was interpreted as signifying that the bacteria, like the platinum, acted as a catalyzer. A rapid growth of bacteria could be obtained in the medium studied only when the potential lay between $rH_2=0$ and $rH_2=14$.—*Authors' summary (transl.).*

1841. **SCHUBERT, JOH. Der Deltoidspatel. Ein technischer Beitrag. [The deltoid spatula.]** *Zentralbl. Bakt. I. Abt. Orig.* 117(7/8): 551-552. 1930.—Adapted for very delicate work in transplanting colonies.

FRUITS

W. A. ROSS, *Editor*

(See also in this issue Entries 1857, 1888, 1895, 1897, 1898, 2601, 2707, 2714, 2715, 2716)

1842. **BARRITT, N. W. A new spray for scale-insects on citrus in Egypt.** *Bull. Ent. Res. [London]* 20(1): 44. 1929.—The author has modified the composition of the resin wash used previously, so as to remove the substances injurious to foliage. The modified wash is made as follows: 1 part resin is dissolved in 3 parts castor

oil; this solution is stirred into 50 parts of water, containing 1 part of .880 ammonia. Spraying may take place at any time between March and October.

1843. **DANIEL, DERRILL M. Biology and control of the blackberry leaf-miner.** *New York State Agric. Exp. Sta. [Geneva] Tech. Bull.* 133: 38p. 1 pl., 5 fig. 1928.—The blackberry leaf-miner (*Metallus rubi* Forbes) is probably a limiting factor in the culture of blackberries in western New York. Injury results from the feeding of the larvae which mine between the surfaces of the leaf. In certain yrs. 60-70% of the leaf surface in a field may be destroyed. Heavy infestations for successive yrs., weaken the plants causing poorly developed fruits of inferior flavor. Experiments were conducted to determine the effect of various insecticides on the eggs, larvae, and the adults. The larvae were found the most susceptible. 4% oil sprays of the highly refined white oil emulsion type gave 18-86% kill. Of the 2 oils tested, Volck averaged 54% control and Medina summer emulsion 39%. The organic insecticide, Derrisol, at a dilution of 1 to 200, averaged 69% control. Experimental evidence is not considered sufficient to make recommendations at present. A Canadian species (*M. bethunei* MacGillivray) has been synonymized with *M. rubi* Forbes. Considering the degree of infestation and actual damage sustained, the blackberry is the preferred host, although dewberries often suffer injury.—*Author's abstract.*

1844. **DEKHTIAREV, N. S. Notes on the scarabaeid beetles attacking vines in Ukraine.** *Bull. Ent. Res. [London]* 20(1): 95-98. 2 pl., 2 fig. 1929.—The most favorable areas for cultivating grapes in Ukraine are the sands of the lower reaches of the Dnieper, the shore of the Black Sea, the Kherson-Odessa districts, and along the Sea of Asov. The appearance of the larvae of various scarabaeid beetles, especially *Polyphylla fullo** L. has been a great obstacle to the exploitation of these barren spaces. The larvae in the soil average about 10-12 to the sq. m. and they often completely destroy the newly planted vines in 1 summer. Among natural enemies are mentioned an asilid fly, *Satanas gigas**, a tachinid fly, *Microphthalma disjuncta* Wied., and hedgehogs, *Erinaceus roumanicus* Barret-Ham. The most active predator of *Polyphylla* is the mole, *Talpa europea brauneri* Satun. Measures of control are discussed, as hand collection of the adult beetles and of the larvae, mechanical obstructions, poison baits, CS_2 applied to the soil by injectors, and paradichlorobenzene (PDB). An effective dose for the larvae is 7 gms. of PDB to 4 sq. ft., at a depth of 2-3 inches, the holes made 2 feet apart in both directions with a vine in the center of each square. Oviposition by *S. gigas* is described and illustrated, also the eggs, larvae, and pupae.

1845. **DUSTAN, ALAN G. Notes on the distribution of the cyclamen mite Tarsonemus pallidus Banks.** *Ann. Rept. Quebec Soc. Protect. Plants* 21: 48-53. 1928-1929 (1929).—This mite has been found causing serious injury to strawberries, stunting the growth of the plants, wrinkling the leaves and preventing the formation of runners and fruit. It is present in Ontario, British Columbia, New Brunswick and Quebec.—*E. H. Dusham.*

1846. **FAES, H. Influence des conditions climatériques sur le développement des insectes et champignons parasites des cultures.** *Rev. Vit.* 72(1875): 461-465. 1930.—The propagation of *Phylloxera vastatrix* is favored by hot dry summers which desiccate the surface soil and induce swarming of the young. In the vineyards of central Europe a marked increase of mildew (*Peronospora viticola*) may be expected in wet yrs., especially if a humid atmosphere prevails during the period when the vines are making the most rapid growth. The danger is considerably lessened if the mean temp. remains rather low, and is exaggerated if the temp. is high, especially if sunlight is intermittent. In dry hot years only slight injury may be feared from the vine worm (*Cochlys ambiguella*) especially if the heat and drought coincide with the oviposition and hatching of the young larvae (end of May to the first of June, and end of July to the first of August). In humid years the larvae cause much damage especially if blossoming is unduly prolonged. *Coniothyrium diplodiella* causes particular damage when hail storms strike the vineyards in July and August. Later the danger is less, as a high sugar content in the grape restricts the abundant development of fungous mycelium. Vineyards on low-lying land suffer most.—*H. Faes (transl. by J. M. Armstrong).*

1847. **PÉREZ, MODESTO QUILIS. Biologia del calcidido Leptomastidea abnormis (Girault) parásito del Pseudococcus citri Risso. [Biology of the chalcid L. abnormis, a parasite of P. citri.]** *Mem. R. Soc. Españ. Hist. Nat.* 15(1): 73-80. 4 fig. 1929.—*L. abnormis* described almost simultaneously in 1916 by Garcia Mercet and by Girault under the respective names of *Leptomastidea aurantiaca* and *Paraleptomastix abnormis,* was again described by Timberlake in 1918 as a new sp. of *Tanaomastix.* Since the generic characters were laid down by Garcia Mercet under the name *Leptomastidea* and the specific characters, as defined by Girault, have been accepted, the species in question is settled as *Leptomastidea abnormis,* synonym, *Tanaomastix.* In connection with the biology of this parasite a description of the adult is given, as a clarification of the synonymy, to which some American writers apparently still adhere. The parthenogenetic reproduction of *Leptomastidea,* especially during Oct.-Nov., is pointed out and the characteristic position of the larva with its head always near the anal end of its host (*Pseudococcus citri*) is described. The number of eggs of a single ♀ average between 200-300 under normal conditions. One half of the egg production is taken as a base for an estimate of ♀♀ during one season to give an approximate idea of the total reproduction during the life of the insect in one season, in order to emphasize the economic importance of this parasite, as an effective agent in the biological control of *Pseudococcus citri.—C. Zeimet.*

1848. **PETHERBRIDGE, F. R. The common green capsid bug.** *Jour. Ministry Agric.* 35(12): 1133-1140. 2 pl., 3 fig. 1929.—This bug, *Lygus pabulinus,* has become a serious pest of currants, gooseberries, strawberries, potatoes, and dahlias, and is also present on apples, pears, plums, cherries, peaches, and a large number of cultivated plants and weeds. Characters are given for distinguishing it from the apple capsid bug (*Plesiocoris rugicollis*) which causes similar damage on currants and apples. There are 2 generations per annum. Eggs are laid in the fall in woody plants such as currants, gooseberries, apples, and roses; in the spring there is usually migration to herbaceous hosts, where summer eggs are laid; the 2nd generation returns to the woody host to lay their winter eggs. In the 1st generation, a secondary migration from strawberries to other herbaceous hosts takes place. Details are given of the damage done to the important host plants and of the habits of the bug in its various stages. Control measures are given.—*Author's summary.*

1849. **RIPLEY, L. B., and G. A. HEPBURN. Olfactory and visual reactions of the Natal fruit-fly, Pterandrus rosa (Ksh.), as applied to control.** *So. African Jour. Sci.* 26: 449-458. 1929.—Mally bait, a sweetened arsenate of lead, does not control the Natal fruit-fly, *Pterandrus rosa* (Ksh.), because of climatic conditions. Experiments are being made with olfactory attractants and obscurants, and with different intensities and colors of light. About 150 volatile substances were tested, such as alcohols, esters, acids, and mixtures of these substances. Attractants and obscurants were tested by (1) trapping in the orchards with baited containers, (2) trapping in the insectary, (3) intensive trapping in small cages under conditions of controlled light, and (4) with a special olfactometer. Pollard bait, oil of cloves, and linalyl acetate are strong attractants. Oil of peppermint is the strongest repellent known. The fly responds to lights of different intensities, but can not distinguish colors, i.e., red, green, and violet.—*C. O. Eddy.*

1850. **ROSELLA, ET. Le dépérissement des abricotiers à Roquevaire. [Decay of apricot trees at Roquevaire.]** *Prog. Agric. et Vit.* 92: 427-430. 1929.—For some years apricot trees have died one by one as though

stricken by "apoplexy." Affected trees near Roquevaire showed unmistakable signs of invasion by *Capnodis tenebrionis* and the author believes that this insect has been chiefly responsible for the death of the trees. He suggests that steps should be taken to control *Capnodis* by destroying all dead wood and trees; by collecting the adults, especially early in the morning when they are sluggish; and by treating the infested trees with paradichlorobenzene. The dosages recommended are 21 to 28 gms. for 2-5 yr. old trees, 31 gms. for older trees, and 14 gms. for younger trees.—*K. S. Markley.*

1851. SCHOEVERS, T. A. C. Appelwantsen en hunne bestrijding. [Apple bugs and their control.] *Tijdschr. Plantenziekten* 36(4): 75-83. 1 pl. 1930.—Lately two bugs, *Plesiocoris rugicollis* Fall and *Lygus pabulinus* L. attacking apples in England, have been found in Holland especially in the district near Hoorn. Their life history, habits and control are discussed.

1852. STANILAND, L. N., and C. L. WALTON. Tar distillate washes as a control for apple capsid bug: Field experiments 1929. *Ann. Rept. Agric. & Hort. Res. Sta. Univ. Bristol* 1929: 101-114. 10 pl. [1930].—The tests were made with the high boiling neutral fractions of tar distillates as prepared by Tutin at the Long Ashton Experiment Station. In numerous tests this material at 10% strength, applied in December, January, or February, controlled capsid bugs on apples very effectively and on currants moderately well. At 6% strength it gave effective control of all "caterpillars" present in the egg stage at the time of application to apples, plums, and black currants.—*W. H. Chandler.*

ECONOMIC ENTOMOLOGY

TRUCK AND GREENHOUSE CROPS

J. E. GRAF, *Editor*

(See also in this issue Entries 1848, 2554, 2662, 2751)

1853. BARNES, H. F. The chrysanthemum midge (Diarthronomyia hypogaea F. Lw.). *Entmologist* [*London*] 61(777): 36-38. 1 pl. 1928.—Brief descriptions of egg, larva, galls, and damage to chrysanthemums, caused by the chrysanthemum midge. Control measures are also given for this pest only recently introduced into England.

1854. BECKWITH, CHARLES S. Control of the blunt-nosed leafhopper. Proc. 60th Ann. Conv. Amer. Cranberry Growers' Assoc. p. 16-21. Aug. 1929.—The blunt-nosed leafhopper (*Euscelis striatulus* Fall.), the vector of cranberry false blossom, is a single brooded insect. In New Jersey the eggs hatch May 30 to June 13, nymphs mature June 23 to August 1, and adults persist throughout September. The greatest number of adults is present about August 1. Eggs are laid in the stem of the cranberry plant. Submerging the bog after most of the leafhoppers have hatched is a recommended control measure, although experiments indicate that spraying with certain pyrethrum-soap or pyrethrum-oil mixtures gives beneficial results. Some notes are given on other leafhoppers present on New Jersey cranberry bogs.—*C. S. Beckwith.*

1855. BONGINI, V. Parassiti di stagione. [Seasonal parasites.] *Boll. Lab. Sper. Fitopatol.* 7(1): 7-10. 1 fig. 1930.—The drying up of flowering plants of Cyclamen persicum cultivated in hothouses owing to the destructive action of the larvae of *Othiorrhynchus sulcatus* Fab. on the roots and tubers is described as showing the partiality of this Curculio for garden plants. Various control methods are given.—*V. Bongini* (*transl. by C. Zeimet*).

1856. BRANDT, E. Gemüseschädlinge unter den Fliegen, Mücken, Käfern, u. a. Insekten. [Insect pests of vegetables.] *Das Aquarium* 1930(April): 63-64. 1930. —Brief notes on numerous species.

1857. CORY, ERNEST N., and P. D. SANDERS. Soil treatment for control of the Japanese beetle. *Jour. Econ. Ent.* 22(3): 556-562. 1929.—A campaign of soil treatment with CS_2 emulsion was conducted during 1927-1928 in a large scale experiment on suppression of the Japanese beetle, *Popillia japonica* Newman. Details are given on dosage, methods of application, and the cost of the treatment. Apparently the natural rate of increase of the beetle was reduced by destroying the grubs.—*W. E. Fleming.*

1858. DOUGLASS, J. R. Hibernation of the convergent lady beetle, Hippodamia convergens Guer., on a mountain peak in New Mexico. *Jour. Econ. Ent.* 23 (1): 288. 1930.—Accumulations of dead beetles were observed at an altitude of 9,462 ft. Many beetles were able to pass the winter at that elevation. Another coccinellid, the Mexican bean beetle, failed to survive the winter there.

1859. DRAKE, C. J., H. M. HARRIS, and R. M. JONES. Concerning onion maggots in Iowa. *Trans. Iowa State Hort. Soc.* 64: 378-385. 17 pl. 1929[1930].—Twelve spp. of flies, 5 of them European, and the others probably indigenous to America, have been reared from onions. As the modes of life and the larval habits of these flies are diverse, some being primary and others secondary invaders, an attempt was made to study the method of egg-laying and the larval habits of each sp. in the field and laboratory. The larvae of the imported onion fly, *Hylemyia antiqua*, the seed corn fly, the lesser bulb flies, the black onion fly, the barred winged onion fly (*Caetopsis aenea*) and, to a very limited extent, the other ortalids, are important primary onion pests. The stratiomyids and certain of the syrphids and ortalids are largely secondary invaders. However, all 12 spp. will breed in decaying or infested onions and in rotting piles of culls and refuse about the onion field; culls, scullions, refuse and remnants of the crop often become important breeding centers for the flies during the fall and spring.

1860. EDWARDS, W. H. Pimento scale in Manchester. *Jour. Jamaica Agric. Soc.* 35(3): 119-123. 1931.—A study of the white fly, *Aleurodicus pimentae*, a pest of the pimento, convinces the author that this insect can be controlled in an effective and lasting manner only by improving the conditions under which the host is grown. The entomophagous fungus, *Aschersonia aleyrodis*, helps to keep *A. pimentae* under control.

1861. GRANDI, GUIDO. Hypopta caestrum Hbn. *Boll. Lab. Ent. Ist. Sup. Agrario Bologna* 3: 221-245. 1 pl., 9 fig. 1930.—*Hypopta caestrum** was observed damaging asparagus. Its life history and possible methods of control are discussed. There are descriptions and figures of the adult, egg, mature larva, and chrysalis.

1862. ISELY, D. The biology of the bean leaf-beetle. [Cerotoma trifurcata Forst.] *Arkansas Agric. Exp. Sta. Bull.* 248. 20p. 10 fig. 1930.—The bean leaf-beetle is the most destructive insect attacking the vegetative parts of beans, cowpeas, and soybeans in Arkansas. The adult beetle attacks its hosts above the ground; the larva feeds upon the roots and nodules. The larval damage is greatest on light sandy soils. The total minimum time required to pass the successive stages from the egg to the sexually mature adult is 26 days. Temp. is the most important factor affecting the rate of development. The average duration of the immature stages is, at 21° C.: egg 13.6 days, larva 16.6 days, prepupa 7.3 days, pupa 10 days; at 30° C.: egg 7 days, larva 8.8 days, prepupa 3.9 days, pupa 5 days. The preoviposition period of non-hibernating beetles varies from 5 to 22 days, with an average of less than 9 days. The average number of eggs secured from each ♀ was 257.7, and the maximum 904. Eggs were deposited only by beetles which had fed

upon host plants in the seedling stage during the first few days of their adult life. It is possible that the number of generations occurring during a season is dependent on the availability of seedling hosts at the time of emergence of adults from the soil. Winter is passed in the adult stage. Beetles were reared through 3 generations.—*D. Isely.*

1863. **KALANDADZE, L. [The rape leaf beetle (Entomoscelis adonidis Pall.) in the vegetable gardens of Tiflis.]** [Text in Georgian; summaries in Russian and German.] *Bull. Inst. Exp. Agric. Georgia [Tiflis]* 1929 (2): 53-58. 2 pl. 1929.—*E. adonidis,* hitherto not reported in Georgia, causes considerable injury to Cruciferae, due to attacks both by larvae and by the beetles. Cress is usually entirely consumed. *E. adonidis* f. *spuria* Jacob. comprises 96-98% of the individuals observed, the parent species being rare. There are at least 3 generations per year. Larvae occur in late March, and pupate after 3 weeks. Beetles appear after 12-14 days pupation, i.e., early in May. Larvae of the 2nd generation appear in the middle of May. Mode of overwintering is not known. Spraying with Paris green or some other arsenate is recommended; use of a 3-5% solution of pyrethrum powder gives good results.

1864. **LANGMAN, A. E. B. The control of woolly Aphis** *Gard. Chron.* [*London*] 88(2295): 519-520. 2 fig. 1930.—Carbon disulphide injected into soil at base of apple trees was a cheap and satisfactory control for the woolly aphis, *Schizoneura lanigera.* About 3 lbs. 2 oz. was sufficient to treat 60 trees. Four injections were made at each tree at distances varying from 12 to 20 inches from the base of the tree.—*J. E. Graf.*

1865. **WILSON, J. W. Cicadas severely damaging Asparagus plumosus.** *Florida Ent.* 14(3): 41-44. 1930.—The injury is caused by the nymphal cicada feeding on the root of the plant. Although this cicada is generally distributed over Florida, they have been reported as doing serious damage only in the vicinity of Jupiter. Very little is known of the life history and habits of this species. Control measures have been started, the result of which will be reported later.

1866. **COTTON, R. T., and R. C. ROARK. Ethylene oxide as a fumigant.** *Indust. & Eng. Chem.* 20(8): 805. 1928.—A dosage of 1 lb. per 1000 cu. ft. of space for 20 hrs. proved to be 100% lethal to specimens of the clothes moth, *Tineola biselliella;* the carpet beetles, *Attagenus piceus* and *Anthrenus vorax;* the rice weevil, *Sitophilus oryza;* the Indian meal moth, *Plodia interpunctella;* the saw-toothed grain beetle, *Oryzaephilus surinamensis;* the red-legged ham beetle, *Necrobia rufipes,* and the flour beetle, *Tribolium confusum.* For commercial fumigation work it is recommended that the fumigant be used at the rate of 2 lbs. per 1000 cu. ft. of space.

1867. **GREMPE, P. MAX. Können Insekten Metalle durchfressen?** *Ent. Rundschau* 48(6): 65-67. 1931.—A discussion of records of insects eating through metal.

1868. **HILL, G. F. Notes on Plodia interpunctella (Indian meal moth).** *Jour. Council Sci. & Indus. Res. Commonwealth Australia* 1(6): 330-340. 1928.—The Indian meal moth has two broods in Melbourne, Australia. The adult moths begin to emerge in Oct. in unheated buildings, reach their greatest abundance during Dec. and Jan. and disappear in Apr. The incubation period of the egg varies with the temp.; at 60-95° F. they hatch in 1-14 days. Temp. above 93° F. is unfavorable for the development of the egg, and 100° F. is always fatal. The development period from oviposition to emergence as a moth varied from 32 to 305 days with an average of 73 days.—*R. T. Cotton.*

1869. **HOYT, L. F. Further fumigation tests with ethylene dichloride carbon tetrachloride mixture.** *Indust. & Eng. Chem.* 20(9): 931-932. 2 fig. 1928.—A 3:1 ethylene dichloride-carbon tetrachloride mixture, used at the rate of 14 lbs. per 1000 cu. ft., at 75° F., was effective against *Tribolium confusum, Plodia interpunctella,* and the webbing clothes moth. The fumigant had no deleterious effect on the baking qualities of wheat or flour, or upon the germination of wheat, oats, beans, peanuts, clover, etc. Various food products fumigated with the mixture gave off the fumigant so as to be edible in from 7 to 8 days.—*H. H. Schwardt.*

1870. **ILLINGWORTH, J. F. Pineapple cannery waste and its insect problems.** *Proc. Hawaiian Ent. Soc.* 7(3): 462-465. 1931.—Because of the attraction of pineapple waste for Nitidulidae it is dried, and sold as cattle food. At one cannery *Musca domestica* was breeding in waste scum on a pond in huge numbers, but was controlled with arsenicals. Factory problems are discussed.

1871. **KRETZMANN. Vom Messingkäfer. (Niptus hololeucus Falderm.)** *Aus. der Heimat* 43(10): 317. 1930.—Account of damage by this species to clothing and household goods in Germany.

1872. **MINAEFF, M. G., and J. H. WRIGHT. Moth-proofing.** *Indust. & Eng. Chem.* 21(12): 1187-1195. 4 fig. 1929.—Animal fibers treated with different chemicals were exposed to clothes moth larvae (*Tineola biselliella* and *Tinea pellionella*) and to the black carpet beetle larvae (*Attagenus piceus*). The methods of testing moth-proofing agents are discussed. Four classes of chemicals have been investigated: thiourea, nitrogenous compounds in general, alkaloids, and fluorides.—*M. G. Minaeff.*

1873. **NAKAYAMA, SHONOSUKE. Biological studies of the granary weevil, Calandra granaria L.** *Proc. Third Pan-Pacific Sci. Congress, Tokyo* 1: 1211-1220. 1926 (1928).—The granary weevil was introduced into Japan proper in 1923 with rice shipped from California. In the vicinity of Yokohama this insect passes the winter in the adult, larval and pupal stages; oviposition begins in April and it is possible to rear 3 or 4 broods a year. Brief notes are given on its biology and on the usual control measures advocated.—*R. T. Cotton.*

ECONOMIC ENTOMOLOGY

FOREST AND SHADE TREES

J. M. SWAINE, *Editor*

(See also in this issue Entries 75, 1956, 2524)

1874. **BORCHERS, FRIEDRICH, und EDUARD MAY. Erfahrungen bei der Arsenbekämpfung des Kiefernspanners in biologischer und technischer Hinsicht.** *Forstwiss. Centralbl.* 52(16): 657-679; (17): 697-714; (18): 744-757. 18 fig. 1930.—Caterpillars of the pine looper, *Bupalus piniarius,* require a fair degree of atmospheric humidity for normal feeding; hence poison applied during dry periods may not be effective. Young caterpillars

are killed by smaller doses than old ones, and can not go as long without eating. Improved models of motor dusters are satisfactory for applying the poison. The most accurate method of testing the results of control measures is by collecting and weighing the droppings, and correlating these with temp. and humidity records. Many caterpillars survive the effects of the As, but form undersized pupae which, in turn, develop into deformed or infertile adults. The caterpillars which survive are likely to be attacked by parasites. Contact poisons are less satisfactory than As because their effect is not cumulative nor persistent beyond the larval stage. —*W. N. Sparhawk.*

1875. FELT, E. P., and S. W. BROMLEY. Shade tree problems. *Florists Exchange* 75(3): 27; (4): 33, 45. 1930.—Insect activities, the restriction of feeding areas, atmospheric and soil dryness, gas mains, paved streets and abnormal air circulation are problems common to city shade tree culture. If trees become defoliated from any cause, it is important to feed, water and spray them liberally. Certain insect pests, such as borers, tend especially to attack weak or defoliated trees; hence, the practice of keeping the trees vigorous is a means of preventing attack. Annual care is most satisfactory. Descriptions of and control methods for the following insect pests are given: hickory bark beetle, two-lined chestnut borer, elm, birch and hemlock borers, *Prionus*, oak leaf rollers, European pine shoot moth, Norway maple leaf stalk borer, birch leaf miner, oak and hackberry gall insects, spruce gall aphid, and a spittle insect of the Scotch pine.—*C. G. Bowers.*

1876. MARCU, O. Contributiuni la oecologia unor distrugatori ai pădurilov Bucovinci. [Ecology of some injurious forest insects of Bucovina, Rumania.] *Communic. Congress Natural. România, Cluj,* 1928: p. 327-336. 1928.—The biological associations of the bark-beetles are described. These insects are found on all species of coniferous trees, young and old, and the associations vary according to the health of the trees. In the healthy trees, are found spp. characteristic of the upper portions, which are restricted to tops and the branches; with an increase of the diseased condition, they descend to the lower parts, which can best be seen on fallen material. In this region, there is 1 generation of *Ips acuminatus*, and 2 of *Xyloterus lineatus*. Through anatomical studies of the ♀ genitalia it can be stated that the ♀♀ of *Pityokteines spinidens* also have a 2nd brood.—*O. Marcu (transl. by S. A. Graham).*

1877. MIDDLETON, WILLIAM. Factors influencing the activity of shade-tree insects and the utilization of these in control work. *Trans. 4th Internat. Congress Ent., Ithaca, N. Y., 1928.* 2: 374-381. 1929.—Insect infestations of shade trees present serious and complex problems. Two types of data have been accumulated, one on life histories and the other relating to insect behavior. The abundance of certain bark beetles is closely correlated with rainfall. Choice trees may be protected to a considerable degree through copious applications of water during dry periods. In the case of pine bark beetles, temp., probably in connection with humidity, is important. The disappearance of plant lice during hot dry weather has often been noted. This may be due to a normal change or alternation of host plant, determined in part by meteorological conditions. Fertilizer applications to boxwood to enable the plants to outgrow injury by the leaf miner and develop more resistance to a disease (*Macrophoma*) may be followed by winter injury, such as splitting of the bark on the trunks and large limbs. Insect attacks on trees are fewer and less serious when the trees are growing under optimum conditions. Defoliation is conducive to borer attack. Fire is also a forerunner of insect attack. The elm borer (*Saperda tridentata*) and others are especially injurious to trees growing under adverse conditions. In many cases, severe borer injury follows a sudden and extensive change in the environment of the tree, as by the clearing of adjacent land with its resultant elimination of normal shade and great reduction in the water supply during the growing season. Recently transplanted trees are very subject to attack by borers. The special behavior of insects has a material bearing upon infestation. The metallic wood borers (Buprestids) and the locust borer (*Cyllene robiniae*) are all sun-loving insects, most likely to be prevalent and injurious in open growths and in situations where the moisture supply is scanty. The probabilities of insect infestation are indicated by the abundance of wintering eggs, as in the case of the white-marked tussock moth or the occurrence of the pest in numbers in leaf mines, as in the case of certain oak leaf miners. There is also the field of insect attraction, suggested by the appearance of large numbers of Buprestids at the burning of a 750,000 barrel tank of oil in California.—*E. P. Felt.*

1878. SIMPSON, L. J. The biology of Canadian bark-beetles. The seasonal history of Dendroctonus simplex Lec. *Canadian Ent.* 61(12): 274-279. 1929.—This species is abundant in dying larch throughout the larch areas of eastern Canada. It may become also a serious enemy to trees weakened by the sawfly, and through other causes. The number of broods per season depends on climatic conditions and degree of infestation. From larch logs moderately infested there were produced only 1 set of egg tunnels and 1 brood of eggs from the parent adults in 1 season; while from logs placed in the same location under the same conditions, but very heavily infested with adults, there were obtained 2, and sometimes 3, sets of egg tunnels in a season.—*L. J. Simpson.*

ECONOMIC ENTOMOLOGY

INSECTS AFFECTING ANIMALS

F. C. BISHOPP, *Editor*

(See also in this issue Entries 1701, 1711, 1749, 1870, 2598, 2744, 2752, 2755, 2756, 2974)

1879. CARBALLO POU, MARIANO. La sarna en el hombre y los animales. [Mange in man and animals.] *An. Escuela Vet. Uruguay* 1(7/8): 279-285. 6 fig. 1929.—Accounts of mange have appeared since 1300. Details of the principal genera of acarids are given and their host distribution studied. Sarcoptic mange of the horse was transmitted to thousands of cavalry soldiers during the great European war. Mention is made of *Demodex folliculorum* as the cause of mange upon the dog and its possible rôle in the transmission of leprosy and cancer. Mention is also made of other kinds of mange and of the sheep mange (Psoroptic mange) in Uruguay, which causes annual losses of 2,500,000 pesos. Various recommendations for combating this plague are given.—*M. Carballo Pou (transl. by J. L. Webb).*

1880. FLETCHER, T. BAINBRIGGE, and S. K. SEN. A veterinary entomology for India, part XI. *Jour. Central Bur. Animal Husb. & Dairying in India* 4(1): 1-5. 3 pl. (1 col.). 1930.—A brief account is given of habits and injury of the Oestridae or botflies, with a key to Indian spp.

1881. GATER, B. A. R., and P. D. RAJAMONEY. A summary of records of Anopheline breeding-places in Malaya. Bull. Inst. Med. Res. Fed. Malay States No. 2. 33p. 1929.—The writers present in tabular form the preference of breeding places of Anopheline mosquitoes in restricted areas of Malaya as shown by 20,318 collections of larvae, and the identification of 126,176 individual specimens. Great adaptability to a variety of habitats is noted, with but few spp. showing definite selection of breeding conditions. The most favored places are pools, slowly flowing streams, swamps, drains and

rice fields. Places of secondary importance are cavities in plants, footprints, broken jars, watering tanks and wells.—*R. O. Christenson.*

1882. GAUT, R. C., and C. L. WALTON. The ox warble flies and their control; with special reference to recent experiments in Worcestershire. *Jour. British Dairy Farmers' Assoc.* 42: 16-28. 1930.—After a brief review of the life history of *Hypoderma lineata* and *H. bovis* and of the literature, the authors detail their experiments of 1929 with various proprietary and non-proprietary dressing materials of which the derris-soap-wash (standardized derris root, 1 lb., soft soap ¼ lb., water 1 gal.) proved to be a reliable and relatively inexpensive remedy. Treatment at 28-day intervals is recommended.

1883. GIBSON, ARTHUR. Insect and other external parasites of poultry in Canada. *World's Poultry Congress* 4(Sect. C): 347-351; résumé sect. 44. 1930.—The parasitic mites, ticks, biting lice, fleas, black flies, mosquitoes, and non-parasitic insects which cause serious losses among poultry in Canada, are briefly described and information is supplied as to methods of control found effective against the more important parasites.—*Author's summary.*

1884. IYENGAR, M. O. T. Jungle in relation to malaria in Bengal. *Indian Jour. Med. Res.* 18(1): 259-266. 1930.—In the province of Bengal, jungles are not connected with malaria and actually form a protection against the breeding of harmful spp. of *Anopheles.* These jungle areas are of 3 types: (1) hill jungle; (2) submontane jungle; and (3) mangrove jungle. The spp. of *Anopheles* occurring in each area are as follows: (1) *aitkenii, annandalei, gigas* var. *simlensis,* and *lindesayi* (harmless spp.); (2) *aitkenii, aitkenii* var. *insulaeflorum, annandalei, barbirostris* and *leucosphyrus* (harmless spp. breeding inside the jungle); *culicifacies, fuliginosus, jamesi, jeyporensis, karwari, maculatus, maculipalpis, majidi, minimus, philippinensis, sinensis,* and *vagus* (malaria transmitting spp. breeding outside the jungle or in open areas); and (3) *barbirostris, fuliginosus, ludlowi, sinensis, subpictus, vagus,* and *varuna* (malaria transmitting spp. breeding within cleared and protected areas).—*S. Ribeiro.*

1885. KEMPER, HEINRICH. Beiträge zur Biologie der Bettwanze (Cimex lectularius L.) I. Über den Einfluss des Nahrungsmangels. *Zeitschr. Wiss. Biol. Abt. A. Morph. u. Ökol. Tiere* 19(1): 160-183. 4 fig. 1930.—The ability to withstand starvation depends on temp., stage of development, and on the constitution of the individual. Under similar conditions young unfed larvae die of starvation first, and adult ♂♂ last. Total lack of food stops larva development and egg laying of adults. Two kinds of partial lack of food are noted: (1) the animal is allowed a full meal at long intervals; (2) partial meals are allowed at shorter intervals. The 1st type results in slow development and a reduced number of eggs per given time interval, while the 2nd type may stop growth and oviposition. The adults must usually take food at least once before they are sexually mature. Insufficient food prolongs life. Even long periods of hunger have no visible influence on the life of individuals which are later allowed to feed normally.—*H. Kemper (from transl. by W. C. Cook).*

1886. MacGREGOR, MALCOLM E. The significance of the pH in the development of mosquito larvae. *Parasitology* 21(1/2): 132-157. 1 fig. 1929.—Previous work had shown that pH of natural waters was correlated with the presence of particular mosquito larvae. Changing the pH of the normal environment affects adversely the development of the larvae. Under bacteriologically sterile conditions this was no longer true. Consequently the acid or alkaline reaction of the medium, within ordinary limits, had no direct effect on larval development. Nevertheless, pH indicated the associations of chemical and biological factors in the breeding-places upon which development of the larvae depended. A new technique is described for the production of a high percentage of successful cultures of *Aedes argenteus* under bacteriologically sterile conditions. The "phase of suspended development" was found to be due to the temporary or complete disappearance of micro-organisms necessary in conversion of the organic materials of the environment to a suitable larval diet.—*From author's abstract.*

1887. TAYLOR, E. L. Liponyssus sylviarum injuring poultry in this country. *Parasitology* 22(3): 313. 1930.—An outbreak in Dorchester, England, was controlled by applying dressings of nicotine sulphate and paraffin to the poultry perches.

(See also in this issue Entries 118, 1223, 1842, 1843, 1844, 1849, 1850, 1851, 1852, 1854, 1857, 1859, 1866, 1869, 1870, 1872, 1874)

1888. BARNES, J. W. Sampling apples in the orchard for the determination of arsenical spray residue. *Indust. & Eng. Chem.* 21(2): 172-174. 1929.—Individual analyses of 300 apples from 4 trees showed for individual apples ranges in arsenical residue of from 0.001 to 0.031 grain As per apple, the mean being 0.011. The ratios for weight were from 0.004 grain to 0.095 grain As per lb. of fruit, with a mean of 0.031 grain. The range in area was from 0.05 grain to 1.30 grains per 1000 sq. in. of area of fruit, the mean being 0.43 grain. A formula is given for calculating the area of an apple from its weight which yields results differing not over 5% from the best mechanical measurements. A statistical study of the data indicates that, in order to obtain a result with a probable error of 5% in the value for mean arsenical residue per lb. of fruit, it is necessary to analyze a sample of approximately 50 apples picked at random.—*Author's summary.*

1889. HALLER, H. L., and F. B. LA FORGE. Rotenone. XII. Some new derivatives of rotenol. *Jour. Amer. Chem. Soc.* 53(6): 2271-2275. 1931.—Chemical studies (oxidation, reduction, etc.) are reported.

1890. HAYNES, RACHEL. Detecting oil in twigs. *Stain Tech.* 5(1): 29. 1930.—A technique, developed during an investigation of the penetration of oil into dormant twigs, is as follows: 1) Cut sections of the twigs on the hand microtome about 20 μ thick, cutting the sections dry in order that the oil will not be displaced by water any more than can be helped. 2) The sections are transferred directly to a saturated solution of sudan IV in equal parts of 70% alcohol and acetone and are stained for 1 min. 3) Wash briefly in water. 4) Transfer to a solution of methylene blue (Unna's polychrome methylene blue, 1 part; water 9 parts) and stain 1 min. or until the tissue is faintly blue. 5) Wash in water, place the sections on a slide, remove the excess water with a blotter or filter-paper, and mount in glycerin.—*Author (courtesy Wistar Bibl. Serv.).*

1891. HOLLAND, E. B., and G. M. GILLIGAN. Electrolytic apparatus for the determination of copper in insecticides and fungicides. *Indust. & Eng. Chem.* 20(5): 533. 1928.—This home-made apparatus for the quantitative determination of Cu in insecticides and fungicides is an improvement over the older types. A figure of the board and wiring diagram is given. Current is supplied by 6 Edison alkaline storage cells arranged to give about 2.4 volts d. c. at about 45 amps. The batteries are charged by a G. E. Tungar rectifier. One-half amp. per electroplating unit deposits 0.15 to 0.20 gm. Cu per hr. Agitation in the electroplating units is obtained by passing compressed air through them. The electrodes are described.—*C. H. Richardson.*

1892. KELSALL, A. Some new insecticide-fungicide combinations. *Trans. 4th Internat. Congress Ent., Ithaca 1928.* 2: 1-3. 1929.—Lime sulphur solutions were precipitated with zinc sulphate, iron sulphate and aluminum sulphate solutions, respectively. The resulting mixtures were tested alone, with nicotine, and with arsenicals. The mixtures with $ZnSO_4$ and with iron sulphate were unsatisfactory. Those with aluminum sulphate showed decided promise, owing to a lessening of foliage injury.—*E. L. Griffin.*

1893. McDONNELL, C. C., and J. J. T. GRAHAM. Deterioration of soap-nicotine preparations. II. *Indust. & Eng. Chem.* 21(1): 70-73. 1929.—Soap-nicotine preparations ordinarily found on the market decrease in nicotine content on storage. Hard soda soaps lose nicotine more rapidly on exposure to the air than potash soaps. However, soft soda soaps and potash (soft) soaps lose it at about the same rate. Excess of alkali or fat in the soaps has no appreciable influence on the rate of loss of nicotine. The loss of nicotine from soap-nicotine preparations made with drying oils (fish oils, cottonseed oil, linseed oil) and packed so that air is not excluded is due mainly to oxidation, the nicotine with part of the fatty acids of the soap being converted into an insoluble condensation product of indefinite composition. The loss of nicotine from soap-nicotine preparations made with non-drying oils (oleic red oil, stearic acid) and stored without air being excluded is due to volatilization of nicotine, no insoluble condensation product being formed. Both hard and soft soaps, whether made from drying or non-drying oils, when packed so that they were completely protected from the air, suffered no loss in nicotine content during two years of storage.—*Authors' summary.*

1894. NELSON, O. A. Vapor pressure of fumigants. I. Methyl, ethyl, isopropyl, and secondary butyl chloroacetates. II. Methyl, ethyl, n-propyl, isopropyl, n-butyl, secondary butyl, and isobutyl formates. *Indust. & Eng. Chem.* 20(12): 1380-1384. 1928.—The vapor pressure for methyl, ethyl, isopropyl, secondary butyl chloroacetates, methyl, ethyl, n-propyl, isopropyl, n-butyl, secondary butyl, and isobutyl formates was determined and the weight of these materials that will vaporize into a 1000 liter or 1000 cu. ft. chamber at certain temperatures is given.—*W. S. Abbott.*

1895. QUAYLE, H. J. Developments in the fumigation of citrus trees. *Trans. 4th Internat. Congress Ent., Ithaca, N. Y.* 1928. 2: 155-161. 1929.—This brief review of the development of HCN fumigation for citrus trees takes up the different types of materials and methods that have been used in the U. S. A. and other countries. Brief reference is made to certain other materials that have been found unsatisfactory and to the question of local tolerance of certain spp. of scale insects to HCN.—*W. S. Abbott.*

1896. ROARK, R. C. Pyrethrum and soap, a chemically incompatible mixture. *Jour. Econ. Ent.* 23(2): 460-462. 1930.—The insecticidal action of Pyrethrum (*Chrysanthemum cinerariaefolium* Trev.) is due to two esters, pyrethrins I and II. These esters are decomposed by aqueous alkali. Pyrethrum flowers or extracts thereof are, therefore, incompatible with soap which hydrolyzes in the water. Pyrethrum is also incompatible with lime-sulphur solution, hydrated lime and other alkaline materials.—*R. C. Roark.*

1897. ROBINSON, R. H., D. F. FISHER, and ANTHONY SPULER. The western cooperative oil spray project (1929). *Science* 71(1843): 440-441. 1930. Quick-breaking emulsions cause severe injury to trees if applied from the time that the buds first show green until the cluster buds separate. Stable emulsions are less likely to cause injury and give equally good insect control. Highly refined oils used in combination with lead arsenate gave improved insect control; the oil has a definite ovicidal value and at the same time increases the larvicidal value of the lead arsenate. Toxicity of oil was found to increase with viscosity within the range 50 to 150 seconds Saybolt. Injury to plants was found to increase with viscosity above 70 seconds S., depending largely upon the number of spray applications. The carbohydrate metabolism of leaves and vegetative spurs of apple trees may be adversely affected by oil sprays. Serious foliage and fruit injury occurred when oil sprays were applied on apple trees carrying unoxidated sulphur deposits. The use of oil sprays late in the summer while heavy deposits of lead arsenate remain on the fruit or the use of heavy oils in combination with lead arsenate was found to complicate seriously the removal of the arsenical spray residues.—*D. F. Fisher.*

1898. STANILAND, L. N., and C. L. WALTON. The Long Ashton tar-distillate wash: Field experiments, 1929. *Jour. Min. Agric. [Gr. Britain]* 36(6): 517-523. 2 pl.; Part II. (9): 828-835. 3 pl. 1929.—Further trials in several fruit sections of England, with this tar-distillate spray confirmed and strengthened results secured during the preceding year in the control of the apple capsid bug (*Plesiocoris rugicollis*). When used at a concentration of 10% during the dormant season the Long Ashton wash gave better control of that insect in the egg stage, as measured by the amount of leaf and fruitlet markings, and by the % by weight and numbers of marked and clean, mature fruits, than either of the 2 proprietary washes known as the modified form of the Long Ashton wash and the so called "standard" tar-distillate wash. The currant capsid bugs (*P. rugicollis* and *Lygus pabulinus*), and caterpillars on apples, plums, and black currants were also more effectively controlled in the egg stages by the new wash than by the proprietary brands. The Long Ashton wash is recommended for use on apples and currants at 10% strength during Dec., Jan., or Mar., where capsid bugs are present, and at 6% strength where those pests are absent. For the control of caterpillars and aphids on plums, a 6% strength is advised.—*O. C. Boyd.*

1899. WILCOXON, FRANK, and ALBERT HARTZELL. Some factors affecting the efficiency of contact insecticides. I. Surface forces as related to wetting and tracheal penetration. *Contr. Boyce Thompson Inst.* 3(1): 1-12. 5 fig. 1931.—Preliminary observations indicate that many spray solutions wet poorly unless a suitable spreading agent is present. Aqueous spray solutions did not penetrate the tracheal system of the larvae of the common tomato worm (*Phlegethontius quinquemaculata*) without a spreading agent. Soaps were the best spreading agents among a number tested. Even with the use of soap as a spreader, the solutions did not penetrate the tracheal system of a freshly killed larva, indicating that respiratory movements or at least vital activity are necessary for penetration to take place. The capillary forces involved as indicated by angle of contact within the tracheae can not alone account for penetration. The toxicity to *Aphis rumicis* of nicotine solutions which contain no spreader (calcium caseinate, Penetrol, and sodium oleate) followed the same order as the spreading coefficients of these solutions.—*F. Wilcoxon and A. Hartzell.*

(See also in this issue Entries 989, 1346)

1900. BETTS, ANNIE D. The ingestion of syrup by the honey bee. *Bee World* 11(8): 85-90. 1930.—The largest average load of sucrose solution observed was 66.6 cmm.; largest individual load, 90 mgm. (70 cmm.). High temp. has more influence than high sugar concentration in increasing size of load. The law of increase

of rate of ingestion with temp. is linear between 10° and 30° C., for given concentration. The rate, at constant temp., varies little with concentration up to 50-60%; above this it falls off rapidly probably owing to the natural rate of pharynx-contraction being overruled by viscous resistance. The maximum weight of sugar per unit time is ingested from a 56-60% solution if the bees can spread apart the trophi while feeding; if not, the optimum concentration will be lower (probably about 50%). Wasps can ingest as fast as, or faster than bees, but take smaller loads.—*A. D. Betts.*

1901. **BORCHERT, A. Ueber die Nosemainfektion der Honigbiene unter besonderer Berücksichtigung der Nosemaseuche.** *Arch. Bienenkunde* 11(1): 1-40. 1930.—The infection of an individual bee by *Nosema apis* is to be clearly distinguished from the infection of the entire colony by *Nosema* parasites. As the individual bee infected by *N. apis* is always sick in the sense of pathological anatomy, we designate the condition in all cases as *Nosema* disease. So far as the colony is concerned in case of infection by *N. apis* we recognize a distinction, whether the colony as such is evidently injured by the parasite, or whether it shows no indication of injury. Where a colony invaded by the parasite appears healthy and strong, we speak of a *Nosema*-attack; in spite of the presence of large numbers of parasite-bearers, the colony proceeds with its work with undiminished vigor. In *Nosema*-attack the number of parasite carriers tends to decrease during the spring and summer, but only in exceptional cases does it entirely vanish. Where there is no such symbiontism but where the entire colony is perceptibly affected and is infested throughout by *Nosema* parasites, we speak of a *Nosema*-epidemic. In spite of the best environment (nectar-yield, weather, temp.) and the bestowal of good care by the beekeeper, the colony either does not develop well or becomes noticeably weaker. In a *Nosema* epidemic the number of parasite-carriers within the colony has a decisive influence upon the fate of the colony. The primary effect of an outbreak of *Nosema*-disease is a deterioration of the functions within the colony. A bee-colony is continually exposed to the most varied possibilities of injury which cause sickness in the brood or bees: intestinal disorders in uninfected situations, poisoning, unfavorable climatic conditions, nectar yield and temp. relationships; poor care from the bee-keeper, especially faulty food; unfavorable location of the apiary, and insufficient shelter for the colonies. The *Nosema* parasite, which may be expected in any place, and which may easily reach any colony, displays only a few sources of injury to the colony. If the functions within the colony weaken, particularly if its inherent resistance and regulatory forces have suffered, the parasite can enter and gain ascendency.—*Author's conclusion (transl. by G. E. King).*

1902. **BURNSIDE, C. E. Sterilizing diseased combs. Growth of Bacillus larvae inhibited by formaldehyde in treated brood remains.** *Glean. Bee Cult.* 58(8): 502-505. 1930.—Formaldehyde does not readily evaporate from the cells after use in treating American foulbrood combs. Growth of *Bac. larvae* in culture is retarded or prevented by formaldehyde that remains in the dead brood. Washing was found to be effective in removing such formaldehyde before preparing cultures.—*C. E. Burnside.*

1903. **MARÉCHAL, P. Sur un nid d'abeilles retournées à l'état sauvage.** *Bull. Soc. Sci. Seine-et-Oise 2 Ser.* 10: 19-23. 1 pl. photo. 1929.—A description of a comb attached to a shrub and arranged somewhat like a small horizontal honeycomb, with reflections on and comparisons with analogous variations in construction in the case of *Golistes* and *Epeira.—P. Maréchal (transl. by A. C. Hodson).*

1904. **MIKHAILOFF, A. S. A summary of what we know about long-tongued bees.** *Amer. Bee Jour.* 70(11): 532-533. Portrait. 1930.—The length of the tongue of all known honeybees is not suited to pollination of red clover. The Caucasian bees have longer tongues than any other race, but the length may decrease considerably with acclimatization and hybridization. All honeybees visit and pollinate red clover, some less, some more, but the southern races do it better than the northern ones. True red clover bees probably do not exist. It is not proven, however, that such bees cannot be produced. —*From author's conclusions.*

1905. **MILUM, V. G. Wintering and production records.** *Amer. Bee Jour.* 70(10): 475-477. 1 fig. 1930.—Records taken from bee colonies wintering with various types of protection show an average production double that of colonies without packing and undivided. For colonies wintered with heavy packing, the average increase was 74 lbs. of extracted honey—a 45% increase. Six divided colonies averaged 44 lbs.; 13 additional in packing cases gave an average of 29.5 lbs.; 4 in double-walled, 27 lbs., and 9 in Celotex, 12 lbs. In regions of a short summer honeyflow and when spring conditions are favorable, package bees are best installed at the beginning of the fruit blooming period in spite of the fact that spring feeding may be necessary in cold, wet seasons.

1906. **MOSOLEVSKY, GREGORY. Abkhasia and the Abkhasian bee.** *Amer. Bee Jour.* 71(3): 120-121. 1 fig. 1931.—The Abkhasian bee is the most popular among Russian bee keepers because of its activity, strength, endurance, productivity, and peacefulness.

1907. **PADDOCK, F. B. The bee moths.** *Jour. Econ. Ent.* 23(2): 422-428. 1930.—This is a review of the systematic history, distribution, life history, food habits, with natural and artificial control methods of *Galleria mellonella* L. and *Achoria grisella* Hub.—*F. B. Paddock.*

ANIMAL PRODUCTION

1908. **ARCHIBALD, J. G. Calf meal studies. I. Laboratory experiments in the improvement of physical condition. II. Feeding experiments with cooked and uncooked meal.** *Jour. Dairy Sci.* 11(2): 119-135. 1928.—Cooking reasonably fine calf meals, although it changes their physical condition, by increasing the dispersion of the solids, does not seem to have any favorable effect on growth. Very fine grinding of calf meals for feeding was impracticable, hence its effect as compared with cooking has not been measured. Digestibility of a calf meal is not significantly affected by cooking.—*Author's conclusions.*

1909. **BARKER, ALDRED F. (illustrated with photographs taken by ROBERT J. STORDY). Prospective development of Peru as a sheep-breeding and wool-growing country.** 174p. Portrait, 93 fig. Privately published, Univ. of Leeds, England, 1927.—The evident object of this book is to encourage sheep production in Peru. Many suggestions are offered as to possible means of improving the industry. The book includes a survey of Peru and other sheep producing countries of S. America. It has the view-point of both manufacturer and producer, and reveals a research worker's insight into the sheep and wool industry. The country is discussed as to possible suitability for sheep production. The native sheep, imported breeds and their crosses are

discussed in relation to their adaptability to the country and usefulness in the sheep and wool trade. One chapter deals with the Alpaca, Llama, Vicuna and their crosses. Many illustrations and charts are included which help to visualize the country and its sheep industry. The appendix contains a discussion of methods of measuring wool to determine diameter of fiber. Tables illustrate the characteristics of wool of different breeds and crosses of sheep.—*F. S. Hultz.*

1910. BÜNGER, H., H. LAMPRECHT, P. GLET, und P. BLÖCKER. Teil I. Fütterungsversuche mit Saflorkuchen an Milchkühen. *Tierernährung* [*Leipzig*] 1(4): 408-420. 1930.—The 2 kinds of safflower cake fed in the experiment described here differ greatly in composition. The high % safflower cakes have a protein content very nearly like that of cracked soybeans, while the low % cakes contain only a little more digestible protein than palmnut cakes and cocoanut cakes. The storage value of the low % safflower cakes is quite low as a result of their high content of hulls, and amounts to only about ½ that of other oil cakes. The feeding of these cakes can be considered only when the price is low, corresponding with the low total nutritive value. The concentrate mixtures with safflower cakes were less readily eaten than the control feeds. No injuries to health were observed as a result of feeding safflower cakes. The safflower cakes distinctly lower the percentage of fat in the milk according to the results of these experiments. The safflower cakes are not complete substitutes for sunflower cakes, since the latter do not have this unfavorable influence.—*Authors' summary (transl. by M. H. Keith).*

1911. COPELAND, LYNN. Effect of heat (oestrum) on butterfat percentage and milk yield. *Jour. Dairy Sci.* 12(6): 464-468. 1 fig. 1929.—On the basis of 2025 recent Register of Merit records, involving 23,000 supervisions, it is concluded that the effect of oestrum on milk yield and butterfat percentage is slight. The difference exhibited seems with most cows to be toward a small decline in milk flow and an equally limited increase in butterfat percentage during the period of heat. Individual cows may show variation in the opposite direction or no variation at all. No compensating increase could be noted in the milk production just prior to the heat period.—*Author's summary.*

1912. DUVAUCHELLE, R. Note sur la caroube. *Bull. Direct. Gén. Agric. Com. et Colon* [*Tunis*] 33(136): 43-49. 1929.—Carob pulp is a valuable feeding-stuff because of its sugar content. The seeds are rich in protein but are not utilized by stock unless ground. Carob supplemented with peanut meal may be substituted for oats or barley. Its value is not realized in Tunis because it has been fed under poor conditions. Two tables give physical and chemical composition of whole beans and pulp alone of grafted and non-grafted carobs.—*J. Cooper.*

1913. GONZALEZ, B. M. Experience in the Philippines with the introduction of pure breed animals to improve the common stock. *Proc. Third Pan-Pacific Sci. Congress, Tokyo* 1: 1142-1150. 1926(1928).—Reviewing attempts during the last 20 yrs. to improve Philippine domestic animals by the introduction, for breeding, of animals from other countries, the author points out that when the breeds concerned are from temperate countries, such as the U.S.A. and Australia, the results of efforts in the Philippines to improve the live stock of the country through importation of foreign breeds has met with little success. When the breeds imported are from tropical countries, such as India and China, the introductions have proved successful. Animals from these countries, however, are not markedly superior to the native stock, and hence the resulting improvement, while obvious, is not outstanding. The principal cause of failure of improved pure breeds of live stock in the Philippines is the presence of such highly infectious diseases as surra, strangles, rinderpest, foot and mouth disease, hog cholera, kidney worms, chicken pox, and fowl cholera, and the relative abundance of parasites, principally helminths. Fundamental to this are the weather conditions prevailing, high temp. and abundant moisture which favor the rapid multiplication of the parasites. Animals from tropical countries are more or less resistant to such diseases through yrs. of adaptation. Another important cause is the fact that conditions of life in the Philippines have not yet made the intensive care of animals a necessity. The domestic animals of the country are raised under natural conditions, and with a minimum of interference and control of man. Under such conditions, the health of imported improved animals, efficient as producers, but delicate in the extreme and bred to be dependent on man for food and protection from unfavorable features of the environment, including inclement weather and enemies, cannot but suffer. As the economic status of the country changes from the extensive plan to the more intensive to accommodate the fast growing population, the methods of husbandry will change so as to include adequate protection to productive live stock. It should then be possible to raise improved breeds with better prospects of success. The conviction is forced upon one, however, that the ultimate solution of the live stock problems of the Philippines will depend in large measure on the development of superior breeds particularly adapted to the country through genetic methods, borrowing physical merits from the breeds of temperate countries and judiciously forming mosaics with the hardy characteristics existing in Oriental animals. Bodily transplantations of breeds from any region cannot be considered as conducive to success.—*From author's summary.*

1914. HAAG, J. R., J. S. JONES, I. R. JONES, and P. M. BRANDT. The physiological effect of rations restricted principally or solely to the alfalfa plant. I. The calcium, phosphorus and nitrogen metabolism of dairy cattle. *Jour. Dairy Sci.* 12(6): 445-455. 1929.—A series of metabolism studies is reported in which the N, Ca, and P balances of dairy cattle were determined for 12 ten-day periods, during which the daily milk yields varied from 9 to 18 kgm. The rations fed consisted of alfalfa hay with and without supplements of starch, linseed oil meal, or di-sodium phosphate. Cows in the early lactation period were usually in positive Ca balance; in negative N balance when the hay contained less than 2.0% N; and always in negative P balance when only alfalfa hay was fed. Feeding di-sodium phosphate changed the negative P balances to slightly positive balances. A general discussion of some of the factors which may be involved in rations restricted principally or solely to alfalfa is presented.—*Authors' summary.*

1915. HINARD, GUSTAVE. Traitement des déchets de poisson et utilisation des sous-produits. I. Les poudres de poisson. *Rev. Trav. Office Pêches Maritimes* [*Paris*] 2(4): 413-441. 1929.—Due to the increasing value of fish-wastes, the interested industries ought to have information upon the composition, character and theoretical principles involved in the various processes of treatment. Hence, studies were made upon fish meals intended for fowl and cattle food; the initial products, their comparative value and conditions favourable to preservation and spoilage; processes of manufacture, such as drying, oil extraction, cooking, etc. (apparatus not described in detail); characteristics requisite for the meal, and for stock foods, their average composition, and some indication as to methods of use in agriculture and stock-raising. This work is based on French industries.—*G. Hinard (transl. by R. H. M'Gonigle).*

1916. ISAACHSEN, H., og OLA ULVESLI. Rotfrugtbladenes kemiske sammensætning, fordøielighet og melkeproduksjonsværdi. [The chemical composition, digestibility, and milk production value of leaves of root crops.] *Fôringsforsøkene Norges Landbrukshøiskole* 24: 1-31. 1929.—A large number of both leaves and roots of rutabagas and other root crops was analyzed, also turnip leaves before and after ensiling. The av. feeding value for milk production for the 3 trials was 1.6 kgm. sand-free dry matter, or 1.4 kgm. organic matter, equalling 1 feed unit. The value is thus lower than that of roots, of which 1.1 kgm. dry matter, or about 1.03 kgm. organic

matter, equal 1 feed unit. The effect of leaves on animals is not as favorable as roots. Leaves have a laxative effect, and have a large amount of oxalic acid. The digestion coeffs. of leaves, as determined with sheep, were as follows: Dry matter 85, organic matter 91, crude protein 79, true protein 73, fat 65, N-free extract 93, fiber 86.—*From authors' summary.*

1917. **JESPERSEN, JOHS. 3die beretning om de af Forsögslaboratoriet og De samvirkende danske Andels-Svineslagterier foranstaltede fodringsforsög med svin. I: Forsög med proteinrige kraftfodermidler som erstatning for skummet melk. II: Forsög med tapiokamel + proteinrige kraftfodermidler som erstatning for korn. [Third report on feeding-experiments with swine. I: Experiments with protein-rich, concentrated food as substitute for skimmed milk. II: Experiments with tapioca-meal plus protein-rich, concentrated food as substitute for grain.]** *132nd Beretn. Forsögslab.* [*Copenhagen*] p. 6-131. 1929.—When fattening pigs of a live weight of 20 to 100 kgm. a daily increase in weight of 600 to 700 gm. is considered satisfactory. This is not achieved by feeding exclusively with maize or with ground barley, wheat, rye, etc., and potatoes, as these feeding stuffs contain too little protein. The feedstuffs rich in protein which might be considered are, however, of a widely different utility. Experiments have shown that skim milk is a high protein feed particularly well suited for pigs. It contains protein of a high biological value, besides readily digestible mineral matter in favorable proportions. A mixture of dried blood containing 78% crude protein and meat- and bonemeal with 35% crude protein as milk substitute also gives a good increase in weight, namely 500 to 600 gm. daily, but the bacon is inferior in quality to the bacon of pigs which have been given skim milk. About 10 kgm. of this mixture was added to each 100 kgm. of grain. Peanut cake, soybean meal and sunflowerseed cake in so great quantities that the protein content of the ration was the same as when skim milk was added, i.e., about 100 gm. digestible protein per feed unit, gave a very slight daily increase in weight (378 to 473 gm.). These rations, furthermore, yield very soft bacon and the pigs are easily attacked by rickets. The experiments were made on 600 pigs.—*J. Jespersen.*

1918. **MARCQ, J. Essai de jugement des reproducteurs bovins par une methode physiozootechnique.** *Bull. Acad. Vét. France* 2(Nov.): 331-335. 1929.—It is to be presumed that correlations existing between the percentage of fat in the blood of the ♀ and the richness of her milk will exist between the % of fat in the blood of the ♂ and his power to transmit aptitude for butter-fat production to his progeny. Observations on a limited number of ♀♀ indicate that this correlation actually exists between the blood and the milk of the ♀ and attempts are being made to determine the reproductive value of the ♂♂ by the same method.—*J. Marcq* (*transl. by J. L. Lush*).

1919. **MEETZ, A., und A. EICHSTÄDT. Teil II. Die Einwirkung von Saflorkuchen auf die Beschaffenheit der Milch und des Butterfettes.** *Tierernährung* 1(4): 421-425. 1930.—In 2 experimental series the safflower cake showed no marked influence on the composition of the milk. The individual values showed only very slight variations. The chemical and physical constants of the butterfat were scarcely changed by the feeding of the safflower cake.—*Authors' summary* (*transl. by M. H. Keith*).

1920. **MÜLLER-LENHARTZ, und von WENDT. Die höchste Milchleistung. Anweisungen für die Praxis auf Grund physiologischer Studien.** (Abhandlungen aus dem Gebiete der Tierhaltung, Heft 5.) 3rd ed. 102p., 10 fig. Paul Parey: Berlin, 1930.—Preparation for lactation is of prime importance because reserves are necessary during growth and maximum performance of the mammary glands. Nutrition must be in accord with the varying efficiency of the digestive tract during the sexual cycle. In almost all cases, mineral supplements (as well as iodine) are necessary for high milking cows. During the preparation of the animals for lactation and during their maximum production the supply of the fat-soluble vitamins usually needs to be supplemented. Unbalanced concentrates should not be used. With the higher milk yields sufficient legumes (hay, forage) should be furnished to increase the biological value of the feed proteins proportionately. Milking the 2 halves of the udder in succession tends to aid the animal during maximum production and leads to increased production in many high yielding animals. Above all, attention must be called to the important significance of good pasture and a long grazing season. The better the pasture and the longer good pasture is available the less the need for supplementary measures, and the better and more adequate the reserves.—*Müller-Lenhartz* (*transl. by A. H. Kuhlman*).

1921. **NEWCOMB, CLIVE. Salt licks.** *Far East. Assoc. Trop. Med. Trans. 7th Cong. Brit. India* 3: 450-452. 1927[1928].—Note on analyses of 7 authenticated salt licks, seeming to indicate that NaCl, other Na salts, Ca or Fe salts are not what the animals frequenting them seek. Iodine may have a relation, but in some cases the ordinary soil of a region had a higher I content than the salt lick.

1922. **RODILLON, J. Le Clapier modele: races, viande, fourrure, soie. [The Rabbit Farm: races, food, fur, silk.]** 232p. illus. S. Bornemann: Paris, 1929, 15 fr.—A book for the practical breeder, discussing the varieties of rabbits and their points for judging; breeding, housing, feeding, hygiene; diseases; the principal products; meat and its preparation for market; fur, its preparation and classification; silk (wool); by-products.—*S. A. Asdell.*

Förderung Moorkultur Deutschen Reiche* 48(10): 181-182. 1930.—Note on the raising of the coypu (*Myocaster coypus*), for the production of nutria fur.

1924. **SCHTSCHJEKIN, V. Zur Frage der besten Methoden der Probe und Paarung der Stuten.** *Zeitschr. Zücht. Reihe B. Tierzücht. u. Züchtungsbiol.* 18(3): 447-454. 1930.—A mating on the 2nd day of the heat period has noticeable advantages over a mating on the 1st day. Mating within the ovulation cycle does not give a high percentage of pregnancy. Since the possibility of pregnancy grows less in succeeding heat periods, the mares must be served repeatedly in each period until the end of the heat season to give a high percentage of pregnancy (70%). A service on the 1st day with a repeated service on the 5th day gives better results than a single service on the 1st day. However, the result of a single service on the 2nd day of the heat period is entirely analogous. The system of repeated services within the same ovulation cycle leads to waste of the sexual powers of the stallion, therefore this system cannot be recommended if many mares are to be mated to the same stallion. There is good reason for using this system of a single service on the 2nd day of heat if the mare should not become pregnant with a single service in the course of a series of heat cycles.—*Author's summary* (*transl. by A. E. Brandt*).

1925. **THERIAULT, J. E. La composition moyenne du lait de la vache canadienne.** *Sci. Agric.* 10(11): 759-760. 1930.—These figures are the result of 71 analyses made of Canadian cow milk at different times of the year from June 1929 up to the date of writing. The analyses were so distributed as to cover as equally as possible different stages of lactation and different kinds of feeding, pasturing, and shelter. The averages are believed to represent very well the average composition of the milk of the French Canadian cow. Compared with other dairy races the Canadian cow is in 3rd position, that is to say, comes immediately after the Jersey and the Guernsey.—*Author's summary* (*transl. by J. L. Lush*).

1926. **TORNOW, ELIZABETH. Über die Bestimmung der "Säure Reserve" in Silofutterextrakten durch elektrometrische Titration.** *Prakt. Blätter* 5(4): 79-84. 1927.—

The "acid-reserve" or buffer value of silage extracts depends principally on the ratio of free to bound or unionized acid. In general as the value of the ratio increases the pH decreases. Tables are given showing the amount of free and bound acetic and butyric acids and of lactic acid in 10 cc. of the extracts.—*C. M. Conrad.*

1930. **HIBBARD, R. P. The physiological effect of ethylene gas upon celery, tomatoes, and certain fruits.** *Michigan Agric. Exp. Sta. Tech. Bull.* 104: 30p. 6 fig. 1930—Studies of the effects of ethylene on color change, growth modification, and chemical change during the blanching process, lead to the general conclusion that for blanching celery ethylene is of little practical importance under Michigan conditions. The optimum temp. range for effective blanching with ethylene was very narrow and too high for use of the gas in the field in late autumn. Celery under boards increased nearly 75% in length of heart leaves during blanching, as compared with little change in the ethylene-treated lot. In ethylene-blanched celery there was less total sugar in the heart and inner stalks than in control plants, a condition apparently due to accelerated respiration and to lack of an extensive carbohydrate reserve. Comparable studies with tomatoes, bananas, oranges, and apples are reviewed. In green ripe tomatoes, ethylene materially shortened the time required for coloration, but the sugar content was much lower than in vine-ripened fruits. Between detached tomatoes ripened in ethylene and in air there was no significant difference in total sugars. Ethylene hastened the yellowing of bananas, even when very green fruit was gassed, and also stimulated the reduction of starch and other reserves but had no beneficial effect on ultimate quality. In oranges, coloration was stimulated with little or no effect on chemical composition. McIntosh apples subjected to ethylene were not reddened, but the green ground color was changed to yellow, and the author suggests that ethylene has no apparent influence on anthocyanin pigments.—*J. W. Wellington* (*courtesy Exp. Sta. Rec.*).

1931. **KAKIZAKI, YŌITI. A new variety, Kuri, of squash.** [In Japanese.] *Agric. & Hort.* 5: 64-67. 1 fig. 1930.—The squash varieties cultivated in Japan belong mostly to *Cucurbita moschata.* In recent years, in the Saitama district (adjoining Tokyo), the cultivation of a new variety, Kuri, which originated from the variety Delicious and belongs to *C. maxima*, has become more extensive, and the product is very favorably received in Tokyo markets. The author describes this variety and discusses the problem of its further improvement.—*Y. Kakizaki.*

1932. **[LAZAREVSKIĬ, M. A.] ЛАЗАРЕВСКИЙ, М. А. Изюмные сорта винограда. [Raisin varieties of grapes.]** [English summary.] Записки Государственного Никитского Опытного Ботанического Сада (*Jour. Gov. Bot Gard., Nikita, Yalta, Crimea*) 12(4): 255-281. 8 fig. 1930. —This paper contains an ampelographic description of all the seedless grape varieties occurring in the grape growing regions of U. S. S. R.—Crimea, Transcaucasia and Central Asia. Besides the varieties which have a world distribution: Sultanina, Sultana and Currant, the Soviet Union possesses a series of very valuable varieties of seedless grapes of which the berries differ sharply in shape, and show colors ranging from green, through yellow-golden, rose, red-purple, to black.—*From author's summary.*

1933. **MILLER, JULIAN C. A study of some factors affecting seed-stalk development in cabbage.** *New York (Cornell) Agric. Exp. Sta. Bull.* 488: 46p. 20 fig. 1929.—With mature cabbage, studies were made as follows: Effect of temp., of a rest period, of etherization, and length of day. The most effective method of hastening seeding tried was storing the mature plants for 2 months at about 40° F., and then growing them at temp. averaging 70° F. With young cabbage plants, studies were made as to the effects of temp., of date of planting, of size of plants and of length of day on premature seeding. A relatively low temp. during the early stages of growth had a marked effect on seed-stalk development. Chemical studies of the young plants showed no definite relation between the composition at the stage of growth when these were sampled and subsequent behavior. In mature plants there appeared to be a positive relation between the accumulation of elaborated foods in the meristematic region and seed-stalk development.—*J. C. Miller.*

FORESTRY

W. N. SPARHAWK, *Editor*

(See also in this issue Entries 47, 58, 61, 64, 65, 67, 69, 109, 115, 125, 2089, 2126, 2143)

1937. **BERTOG, HERMANN. Beispiel einer örtlichen Ertragstafel für Kiefer.** *Deutsche Forstzeitg.* 46(15): 365-370. 1931.—Data are presented on the actual yields during 30 yrs. from a 517-ha. Scotch pine forest. The yields from thinnings averaged 23.3% larger than given in Schwappach's yield table, and the average diam. of the trees at any given age was 4-6 cm. larger, although there were fewer trees.—*W. N. Sparhawk.*

1938. **BRUTTINI, ARTURO. Dictionnaire de sylviculture en cinq langues. (Encyclopédie Économique de Sylviculture Vol. 4.)** 384p. Portrait. Paul Lechevalier: Paris, 1930.—Definitions in French of 4600 terms, with German, English, Spanish and Italian equivalents.—*W. N. Sparhawk.*

1939. **CHIRITA, CONSTANTIN D. Untersuchungen über den Nährstoffgehalt der Waldhumusauflagen unter Berücksichtigung der mineralischen Unterlage und Betrachtungen über ihre Bedeutung für die Ertragsfähig-**

keit der Waldböden. *Forstwiss. Centralbl.* 53(13/14): 468-478, 499-513. 3 fig. 1931.—Samples of humus and mineral soil under beech and spruce in 12 localities were analyzed by the electro-ultrafiltration method (as used by Köttgen and Diehl) to determine the total content of bases and of CaO, K_2O, and P_2O_5, and their rate of solution. The various soils differed greatly in these respects, but in general there was a fairly close correlation between the base content of the mineral soil and of the overlying humus. The humus contained a larger quantity of soluble bases, particularly CaO, than the mineral soil. No relationship could be established between the productivity of the soils and their content of plant foods.—*W. N. Sparhawk.*

1940. CLEPPER, HENRY E. The deer problem in the forests of Pennsylvania. *Pennsylvania Dept. Forests & Waters Bull.* 50: 5-45. Map, 17 fig. 1931.—During the last 40 years deer, which had become scarce in Pennsylvania, have increased to some 800,000 head, or about 3 times the optimum carrying capacity of the forests. In many localities they have destroyed the undergrowth, including mountain laurel and rhododendron, effectively prevented natural forest reproduction, and even destroyed extensive plantations of various hardwood and conifer species. The birch-beech-maple type appears to furnish the most food per acre and to suffer the least damage. The overpopulation of deer has led to a deterioration in the size and vigor of the deer and has also, by destroying their food and cover, greatly reduced the small-game population. Suggested remedies include reduction in size of the herd, shooting of does so as to bring them into better balance with the bucks, and more even distribution of the deer throughout the forested portions of the State.—*W. N. Sparhawk.*

1941. FABRICIUS, L. Forstliche Versuche. X. Die Samenkeimung von Sorbus aucuparia L. *Forstwiss. Centralbl.* 53(12): 413-418. 1931.—Seeds of mountain ash are widely distributed by birds. Naturally, they germinate very slowly. Attempts to hasten germination by soaking in various solutions, including some similar to those in birds' digestive tracts, were all failures. Other tests showed that either dry or fresh seed exposed to frost over winter germinated fairly well in the spring, provided it was kept in the dark. Although of no commercial importance, this tree has some silvicultural value and also affords food for certain mammals and birds.—*W. N. Sparhawk.*

1942. FABRICIUS, L. Forstliche Versuche. XI. Pflanzenauslese im Saatbeet. *Forstwiss. Centralbl.* 53(13): 449-457. 5 fig. 1931.—In 1922, 2000 of the largest (average weight 9.31 gm.) and 2000 of the smallest (average weight 1.98 gm.) 2-yr.-old pines in a nursery bed were transplanted in test plots, and in the spring of 1925 those surviving were planted in the field. At the end of 1927 the average height of the large (A) trees was 106 cm. and of the small (B) trees 79 cm., although the growth of the A trees was relatively more retarded for 2-3 yrs. after planting, because of unavoidable injuries to their larger root systems. However, 13.3% of the B trees were taller than the average A trees, and 13.3% of the A's were shorter than the average B's. At the end of 1930, the average heights of A's and B's were 217 and 185 cm., respectively. The tallest 40% of the B's grew as fast from 1927 to 1930 as the tallest 40% of the A's, but the other 60% of the B's fell farther behind the corresponding A's. This indicates that about 40% of the smaller plants are smaller because of accidental external conditions and will do as well as the larger plants after planting out. The small size of the remaining 60% is due in part to inherited characteristics. Except for the extremely small and weak seedlings (usually about 10% of the total number), it is not advisable to discard the smaller plants, since the chances are at least even that they will make as good trees as the large ones. Tests on a smaller scale with 1- and 2-yr. spruce seedlings indicated that in transplanting 1-yr. spruce only the very smallest should be thrown out, but a somewhat larger proportion with 2-yr. seedlings. Results with larch indicate that a large part of the smaller plants should be discarded, although it may not be possible to select the right ones until planting out, when they are 4-5 yrs. old.—*W. N. Sparhawk.*

1943. FISCHER, KARL R. Wie gehen Hähersaaten vor sich, und welche forstliche Bedeutung kommt ihnen zu? *Deutsche Forstzeitg.* 46(21): 519-522. 1931.—Jays are largely responsible for spreading acorns and beechnuts at considerable distances from the parent trees. This may be of considerable importance in the introduction of oak and beech into conifer forests.—*W. N. Sparhawk.*

1944. FRAHNE, CURT. Gedanken zur Technik und Wirtschaftlichkeit der Kiefernverjüngung im Privatwalde. [Methods and economic practicability of reproducing pine in private forests.] *Deutsche Forstzeitg.* 46(30): 731-734. 1931.

1945. GEIGER, RUDOLF, und HANS AMANN. Forstmeteorologische Messungen in einem Eichenbestand. *Forstwiss. Centralbl.* 53(10): 341-351. 5 fig. 1931.—Measurements are given of the average wind velocity and the periods without wind, below, in and above the crowns of oak forest, both pure and underplanted with beech.—*W. N. Sparhawk.*

1946. HOHENADL, W. Alte und neue Verfahren von Bestandsberechnungen. *Forstwiss. Centralbl.* 53(11/12): 381-392, 434-446. 2 fig. 1931.—The old methods of computing volumes and values of stands by the use of volume tables and form factors or by use of sample stems of average basal area are not sufficiently accurate for scientific purposes. Both lead to onesided errors that cannot be corrected by statistical methods unless a large number of sample trees are measured. A new method is explained, which uses only 2 sample trees chosen by statistical methods (average diam. of all trees in the stand, ± the standard deviation).—*W. N. Sparhawk.*

1947. HOLLSTEIN, W. Bodentypus und Waldtypus auf Küstendünen. *Forstwiss. Centralbl.* 53(8): 286-301. 2 fig. 1931.—The coastal dunes near Danzig, which have been in process of formation for 8,000 to 10,000 yrs., exhibit a variety of soil types, depending on age, and a corresponding variety of soil flora. Both soil flora and forest composition are influenced by the presence or absence of an A_1 soil horizon of decomposed humus.—*W. N. Sparhawk.*

1948. KOSSENAKIS, GEORG. Skizze des griechischen Waldes. *Forstwiss. Centralbl.* 53(1): 31-39. 1931.—Because of the mountainous character of the country, all of the forest should be considered protection forest. There are 5 forest zones: (1) Zone of evergreen oaks and laurel, characterized also by a large number of chaparral species. The most valuable tree is *Pinus halepensis*. Forest fires do much damage in this zone. (2) Chestnut zone, containing also numerous other species of hardwoods and several conifers; (3) beech zone, associated with various hardwoods and with *Abies cephalonica* and *Pinus laricio* towards its upper limits; (4) fir zone, consisting of *A. cephalonica* and other conifers; and (5) alpine zone, with stunted shrubby species.—*W. N. Sparhawk.*

1949. LANG, RICHARD. Echte und unechte Krümelung und Gare. *Forstwiss. Centralbl.* 53(9/11): 309-324, 351-367, 393-403. 1931.—Lang points out the differences between Krümelung, which is the aggregation of fine clay particles into grains the size of fine sand, resulting from physical and chemical action of K, Na, Mg, and especially Ca salts; mechanical loosening of the soil by cultivation and by the roots of vegetation, which produces large pores that do not last over several yrs.; and mellowness (Gare), which results from the action of living organisms in the soil, chiefly bacteria, fungi, earthworms, etc., and also from the decomposition of leaf litter and the protective effect of legumes such as lupine. This develops a more porous soil than mere Krümelung, and thereby favors the growth of trees. At least for the less exacting species, such as pines, the porosity of the soil, because of its relation to water capacity and water, air, and CO_2 circulation, is more important than the supply of assimilable N. The beneficial effect of lupine

under pine and spruce is due more to its preventing the soil from drying than to its accumulation of N.—*W. N. Sparhawk.*

1950. LÜHDORF, ARNIM. Die Bedeutung des Handels mit aussereuropäischen Harthölzern (unter besonderer Berücksichtigung der Stellung Hamburgs). 87p. Published by the author: Giessen, 1931.—This is a general review of the hardwood resources and commerce of Asia, Australia, Africa and America, with special emphasis on the tropical hardwoods. Hamburg is still the most important market for foreign hardwoods in continental Europe, although it has a smaller share of the trade than before the war. Germany will always need to import hardwoods, and will have to get them mostly from the tropics.—*W. N. Sparhawk.*

1951. MIRA, FRANCISCO. Las dunas de Guardamar. [The dunes of Guardamar.] *España Forest.* 14(158/159): 81-83; (160): 113-115; (161/162): 146-147. 1929; 15 (165): 12-14. Illus. 1930.—These dunes, covering 846 ha. near the mouth of Rio Segura in Alicante province, Spain, have been advancing 4 meters a year along a 16-km. front, thus ruining about 6 ha. of fertile land annually. Their movement has been checked by use of brush and other barriers, sowing of beach grass and other cover crops, and planting of *Pinus pinea, P. halepensis,* and *P. maritima,* and on an experimental scale *Casuarina, Juniperus* spp., eucalypts, etc. All of these are grown in nurseries among the dunes. Firebreaks 15 m. wide are covered with the succulent *Mesembryanthemum crassifolium.*—*W. N. Sparhawk.*

1952. MOROSOW, G. F. Die Lehre vom Walde. [Translated from the Russian by Selma and Hans Ruoff and Buchholz.] xxxii+375p. Portrait. 63 fig. J. Neumann: Neudamm, 1928, Pr. 21 m.—This work deals with the biology and silvical characteristics of forest trees, of forest stands, and of forest types. Bibliography (7 pp.) of Russian and German literature.—*W. N. Sparhawk.*

1953. PERRY, GEORGE SARGENT. Forestry in Sweden and adjacent lands from the viewpoint of an American forester. 276p. Map. 15 fig. Pub. by Author: Pennsylvania State Forest School, Mount Alto, Pennsylvania, 1929.—This book describes the historical, legal, and economic aspects of the development of Swedish forestry, and emphasizes particularly the methods and policies of silviculture and forest management. Chapters are devoted to description of the forest regions and tree species, natural regeneration, artificial regeneration, thinnings and improvement cuttings, land drainage, afforestation of heath and dune lands, forest regulation and working plans, and forest administration.—*W. N. Sparhawk.*

1954. PIANI, GIOVANNI. Sull'acclimatazione di alcune specie forestali esotiche in Cirenaica. [Acclimatization of exotic trees in Cyrenaica.] 19p. 8 pl. Ist. Agric. Coloniale Ital.: Firenze, 1930.—For forest planting in Cirenaica the better native spp. should generally be used, especially *Pinus halepensis, Cupressus sempervirens* var. *horizontalis, Quercus ilex, Tamarix articulata, Ceratonia siliqua,* and *Olea europea.* In some places, especially on the plateau, exotic species may be preferred for ornament and shade, windbreaks and roadside planting. Many spp. have been tried out, though for only a few yrs. in most instances. Among the more successful are several eucalypts (*E. gomphocephala* and *E. rostrata* are best), acacias (*Albizzia* and *Acacia* spp.), *Casuarina* spp., *Parkinsonia aculeata, Melia azedarach, Cupressus pyramidalis,* and *C. macrocarpa* (or *C. lambertiana*), and as secondary species *Eleagnus* spp. and *Phytolacca dioica.* Most of these grow faster than the native trees. Several others still under observation will probably do well. A large number (listed) have failed so far, but some might do better under different conditions.—*W. N. Sparhawk.*

1955. QUEVEDO, MIGUEL A. de. La estación forestal del puerto de Vera Cruz y sus enseñanzas. [The forest station of the port of Vera Cruz.] *Mexico Forest.* 7(12): 247-254. 1929; 8(4): 51-66; (9): 215-223; (10): 227-239. Illus. 1930.—Control of dunes in connection with development of the port is described. Fixation of the sand was undertaken in 1908 under the direction of French experts and was completed in 1913, using chiefly *Arundo donax, Ipomoea pes-caprae* and *Acacia cornigera.* The plantations were neglected during the revolutions and the World War and were destroyed by grazing. Work has since been resumed. In 1908 there were very few trees in Vera Cruz, but so many have been planted that it will soon be one of the best wooded cities of Mexico. *Casuarina cunninghamiana, C. stricta, Tamarix plumosa,* and *Acacia lebbek* have done best; eucalypts and pines did not thrive.—*W. N. Sparhawk.*

1956. ROHMEDER, E. Anbaufläche und Gefährdungen der Strobe im bayerischen Staatswald. *Forstwiss. Centralbl.* 53(9): 325-339. 2 maps. 1931.—In 1926 *Pinus strobus* occupied 1934 ha. or 0.23% of the State forest area in Bavaria. Stands over 60 yrs. old comprised 1.6% of the total; and 31-60 yrs., 21.7%. The pine suffers from many enemies. Deer are especially destructive to young saplings, on which they rub their antlers. Blister rust had attacked 1677 ha. in 1926; the stand on 620 ha. was severely damaged. Even more destructive is the fungus *Agaricus melleus,* which had severely damaged the stand on 1121 ha. out of the 1794 ha. on which it was found. No means of combating this fungus is known, but there are several ways to control blister rust. White pine is relatively free from snow breakage at low altitudes, but is badly damaged above 600-750 m. Scale insects, weevils, mice, woodpeckers, and drought cause more or less damage locally.—*W. N. Sparhawk.*

1957. SCHMIDT, WERNER. Unsere Kenntnis vom Forstsaatgut. 256p. 54 fig. Der Deutsche Forstwirt: Berlin, 1930.—This is a comprehensive review of present knowledge regarding determination of quality of seed, seed collection and storage, seed testing and control.—*W. N. Sparhawk.*

1958. SCHWARZ, HANS. Die für den Anbau in Mitteleuropa bedeutungsvolleren Hickoryarten. *Forstwiss. Centralbl.* 53(13): 461-467. 1931.—The following hickories should do well on suitable sites in central Europe: *Carya alba, C. glabra, C. laciniosa, C. ovata,* and *C. cordiformis.* They should be grown in mixture with other hardwoods (oak, ash, beech, etc.) or possibly in pure coppice stands on a 40-60 yr. rotation. Thinning should commence at about 30 yrs. and be repeated at frequent intervals.—*W. N. Sparhawk.*

1959. STEWART, GEORGE W. Big trees of the giant forest, Sequoia National Park in the Sierra Nevada of California, their life story from the blossom onward. 104p. Illus. A. M. Robertson: San Francisco, 1930.—The vitality of these trees and their ability to recover from severe injury are especially noteworthy and account for their great age. Their only really serious enemy is fire.—*W. N. Sparhawk.*

1960. VOIGT. Erziehung von Qualitätskiefern mit niedrigen Kulturkosten. *Deutsche Forstzeitg.* 46(17): 417-419. 1931.—A burn was successfully restocked by broadcasting a mixture of pine, spruce and larch seed (11 kgm. per ha.) and then driving a band of sheep over the area for several days when the ground was slightly damp. The sheep ate the competing vegetation and trampled the seed into the ground.—*W. N. Sparhawk.*

1961. WITTICH. Ueber das Wachstum von Vollumbruchkulturen auf physiologisch gesunden Böden. *Deutsche Forstzeitg.* 46(20): 491-494. 3 fig. 1931.—Pine planted on fully cultivated sandy diluvial soil grew much more rapidly for 10-12 yrs. than that planted by the usual furrow method, but as soon as the stand closed it lost its advantage. The rapid early growth was due to the absence of competition of grass and weeds rather than to any improvement in quality of the soil. Cultivation of physiologically unhealthy soil might improve it so the effect on tree growth would be more lasting.—*W. N. Sparhawk.*

1962. **ANACHIN, J. K. Über einige neue Chlamydomonas-Arten.** *Arch. Protistenk.* 73(1): 131-136. 4 fig. 1931.—*Chlamydomonas* **oblonga*** (p. 131); *C.* **insignis*** (p. 133); *C.* **skujae** (p. 134); *C.* **vulgaris*** (p. 135); *C.* **brevicauda*** (p. 136). All are from vicinity of Kharkow. Comparative notes are given for *C. mucosa* (Korschikoff) Pascher. —*L. E. Noland.*

1963. **BACHRACH, EUDOXIE, et DENISE PILLET. Etude des cendres des diatomées sans carapace. [Ash of diatoms without frustule.]** *Bull. Histol. Appl. Phys. et Path.* 8(2): 33-37. 2 fig. 1931.—Diatoms experimentally deprived of frustule live and reproduce with a very changed form for years. Microincineration shows a mass of calcium in and some granules arranged about the nucleus. A calcium band outlines the cell and at both poles small masses indicate the position of the valves.—*J. G. Sinclair.*

1964. **CAPT, LUCILE. The morphology and life history of Antithamnion.** *Publ. Puget Sound Biol. Sta.* 7: 369-389. 37 fig. 1930.—Working with *A. pacificum*, *A. occidentale* and *A. defectum* the author secured quite a close series in the development of the cystocarp. The tetrasporangia are formed in groups of 2 or 3 as in *A. uncinatum*. *A. defectum* may be distinguished from *A. occidentale* by the manner in which the gland cells are formed. The branching is quite variable and leads to doubt of the value of *A. uncinatum* S. & G. and *A. pygmaceum* S. & G.—*T. C. Frye.*

1965. **CHOLNOKY, B. A Pennatae csoport kovamoszatainak ivaros szaporodâsa. [Sexual propagation of the Pennatae of Diatomeae.]** [In Hungarian, with German summary.] *Bot. Közlemények* 27(5/6): 81-102. 1930.—A comprehensive discussion of the results of recent investigations.—*C. Schermann.*

1966. **DU RIETZ, G. EINAR. Three species of marine algae new for the Swedish part of the Baltic.** *Bot. Notiser* 1930(5): 360-367. 1930.—The southeast corner of Södertörn, south of Stockholm, with free exposure to one of the deepest basins of the Baltic, has been little studied in respect to the algal flora. As a preliminary report of investigations in this region in 1929-1930 the author notes *Desmotrichum balticum* Kütz., a species known from Finland and the western coast of Sweden and probably common in the Swedish part of the Baltic, but hitherto overlooked. The plurilocular sporangia show transitions between the intercalary and typically lateral types (represented by *D. balticum* Reinke and *D. scopulorum* Reinke respectively), but the immersed broadly conical type was most common. The varying forms in the Baltic (except Reinke's original *D. scopulorum*) are maintained as *D. balticum*, but the specific value even of *D. scopulorum* is questioned. *Leathesia difformis* (L.) Aresch. appeared in a small form (always less than 1 cm. diam.) near Nynäshamn, previously found on the Swedish coast only west of Öresund. It is probably restricted to this area and is associated with the unusual maritime lichens, *Lecania aipospila* (Wahlenb.) Th. Fr. and *Caloplaca thallincola* (Wedd.) Dr. To what extent these associations are due to hydrographical conditions must be decided by further study. *Scytosiphon lomentarius* (Lyngb.) J. Ag. is abundant in several localities in the uppermost *Fucus-Pylaiella* belt on strongly exposed shores. It has probably been overlooked due to the fact that fruiting occurs only in the spring. The specimens were slender and may be referred to f. *fistulosa* Reinke (=f. *cylindrica* Setchell & Gardner). Articulate forms were also found.—*H. K. Svenson.*

1967. **FRÉMY, PIERRE. Les Myxophycées de Madagascar.** *Ann. Cryptogamie Exotique* 3(4): 200-230. 9 col. pl. 1930.—Contains biological notes and a systematic list of species of which 14 are new to Madagascar, 2 spp. and 1 var. new to Equatorial Africa, 13 new to Africa, and *Entophysalis* **perrieri*** (p. 207). Key to spp. of *Entophysalis* is given.

1968. **FRYE, T. C. Splitting of the leaf of Nereocystis.** *Publ. Puget Sound Biol. Sta.* 7: 413-416. 5 fig. 1930.—The writer believes that the nearest relative of *Nereocystis* is *Pelagophycus*, and finds some reason for such a belief in the first few splittings of the original blade of *Nereocystis*.—*T. C. Frye.*

1969. **FRYE, T. C. Union of gametes in Scytosiphon.** *Publ. Puget Sound Biol. Sta.* 7: 416. 1930.—A report of the finding of union of gametes as stated by Kuckuck. —*T. C. Frye.*

1970. **GEITLER, LOTHAR. Ein grünes Filarplasmodium und andere neue Protisten.** *Arch. Protistenk.* 69(3): 615-636. 1 pl., 15 fig. 1930.—The following new genera and species are described from a marine culture from Canary Islands: **CHLORARACHNION,** with *C.* reptans* nov. gen., n. sp. (p. 616) a green filarplasmodium; **SARCINOCHRYSIS** with *S.* **marina*** nov. gen., n. sp. (p. 627) of Chrysophyceae; **PLATYCHRYSIS,** with *P.* **pigra*** nov. gen., n. sp. (Isochrysidaceae) (p. 631) a Chrysomonad; **RHODOSORUS,** with *R.* **marinus*** nov. gen., n. sp. (p. 633) a Red Alga.—*G. M. Robertson.*

1971. **GEITLER, LOTHAR. Rhodostichus n. gen.** *Arch. Protistenk.* 73(2): 305-310. 4 fig. 1931.—**RHODOSTICHUS expansus*** Geitler & Pascher (p. 305, 310) was found in brooks in Carinthia in July 1930. Though similar to purple bacteria the author concludes that it is a blue green alga. It has purple red color, cells 0.6×3 μ in parallel rows 50 μ long, tightly packed pyramid-wise, each cell and filament encapsulated in jelly. Reproduction is by transverse division only. Preliminary tests indicate the pigment to be phycoerythrin. —*L. E. Noland.*

1972. **GOEBEL, K. Die Deutung der Characeen-Antheridien. Ein Versuch.** *Flora* 24(4): 491-498. 3 fig. 1930.—Sections of groups of gametangia of *Chara* in various stages of development showed that the entire group of oogonia and antheridia are developed from a structure comparable to a leaf. Oogonia are differentiations of single leaflets, and the so-called "antheridia" are derived each from 8 fused leaflets. Antheridial filaments are the ultimate branches of these leaflets. Neither the "antheridium" nor the antheridial filaments can be homologised with the antheridium of the moss, but the antheridial filament can readily be compared with series of unicellular antheridia of the algae.—*F. Drouet.*

1973. **GRAN, H. H., and E. C. ANGST. Plankton diatoms of Puget Sound.** *Publ. Puget Sound Biol. Sta.* 7: 417-516. 95 fig. 1931.—Descriptions of the species of diatoms found in the general region in the plankton of the ocean. All the species and varieties are illustrated, and most of the illustrations are original. There are keys to and descriptions of the genera and species. Thirty-two genera are reported, and 95 species and varieties, including *Thalassiosira* **aestivalis** Gran* (p. 436), *T.* **pacifica** (p. 437), *Coscinodiscus* **angstii** Gran* (p. 443) and var. **granulomarginata*** (p. 444), *C. centralis* var. **pacifica*** (p. 446), *C.* **wailesii*** (p. 448), *Chaetoceros* **approximatus*** (p. 476), *C.* **crucifer** Gran* (p. 484), *Tropidoneis antarctica* var. **polyplasta*** (p. 501), and *Nitzschia closterium* var. **recta*** (p. 503).—*T. C. Frye.*

1974. **GROSS, ILSE. Beiträge zur Entwicklungsgeschichte der Protophyten. VII. Entwicklungsgeschichte, Phasenwechsel und Sexualität bei der Gattung Ulothrix.** *Arch. Protistenk.* 73(2): 206-234. 20 fig. 1931.—*Ulothrix zonata* and *U. oscillarina* were cultivated under artificial light on Mainx' Volvox agar at 8-10° C. In *U. zonata* higher temp. induced fragmentation of the filaments, brought about by the growth of long processes from the ends of occasional cells in the filaments. Leaving the filaments too long on a plate without renewal of nutrients induced the growth of long branching hypha-

like processes from certain cells, and even causing branching of the filaments in some cases; freezing, drying or flooding with fresh nutrient solution induced zoospore formation. Cell-division, zoospore formation and copulation are described in some detail. The reduction division occurs when the zygote germinates. Gametes from the same filament will not copulate with each other; *U. zonata* is accordingly dioecious. Three types of filaments exist: those producing zoospores only; those producing gametes only; and those producing both. Since each of these may be either ♂ or ♀, there are in reality 6 different kinds of filaments in the species.—*L. E. Noland.*

1975. **GROVES, JAMES. On the antheridium of Chara zeylanica Willd.** *Jour. Bot.* 69(1820): 97-98. 1 fig. 1931.—In all specimens examined from various parts of the world, antheridia with 4 lozenge-shaped shields were found.—*A. L. Grant.*

1976. **HAGEMANN, E. Beitrag zur geographischen Verbreitung der Algen in der Umgebung von Hannover.** *Jahresber. Naturhist. Ges. Hannover*, 1924/25-1928/29. 75: 40-80. Map. 1930.—An extensive list of Myxophyceae, Flagellatae, Heterokontae, Dinoflagellatae, Bacillariophyta, and Chlorophyceae, and a few Rhodophyceae and Charophyta, with local habitats.

1977. **HUSTED, LADLEY. Cell wall of Vaucheria geminata.** *Bot. Gaz.* 91(2): 219. 1931.—The "inner layer" of the empty cell wall (the protoplast having flowed out through a cut end) gave no reaction with the cellulose reagents (iodine KI and 70% H_2SO_4), but the end at the cut gave a faint cellulose test. The author suggests that the cell wall is of 3 layers: outer, of pectic compounds; middle, of cellulose; and innermost, extremely thin, of "pectose substances or of cellulose heavily impregnated with pectose."

1978. **KÖRNER, O. Über Anheftungsstellen von Algen auf den Schalen von Wasserschnecken. [Attachment of algae on the shells of water snails.]** *Ber. Senckenberg. Naturf. Ges.* [*Natur u. Mus.*] 61(2): 70-71. 1 fig. 1931.—*Enteromorpha* on the apex of *Limnaea stagnalis; Cladophora* on the umbo of *Planorbis* and on the apex of *Physa acuta.*

1979. **KUCKUCK, PAUL. Fragmente einer Monographie der Phaeosporeen. Edited, after the death of the author, by WILHELM NIENBURG.** *Wiss. Meeresuntersuch. Komm. Untersuch. Deutsch. Meere in Kiel u. Biol. Anst. Helgoland. Abt. Helgoland* 17(4): iv & 93p. 155 fig. 1929.—This paper is a collection of figures and notes assembled by Kuckuck in anticipation of a monograph of the Phaeosporales, organized for publication after his death by WILHELM NIENBURG. The primary division is made into **HAPLOSTICHALES** and **POLYSTICHALES**, in the latter group the primary cell row becoming subdivided by longitudinal cell walls. Fourteen families are offered in the first sub-order: *Ectocarpaceae, *Choristocarpaceae, Cutleriaceae, *Elachistaceae, *Corynophlaeaceae, *Myrionemaceae, *Mesogloeaceae, *Myriogloeaceae, *Myriocladiaceae, *Acrotrichaceae, *Spermatochnaceae, *Desmarestiaceae, *Sporochnaceae and *Splachnidiaceae, while in the Polystichales 12 families are included, but studies of representatives were not available for this paper: Stictyosiphonaceae, Chnoosporaceae, Asperococcaceae, Litosiphonaceae, Scytosiphonaceae, Punctariaceae, Sorantheraceae, Dictyosiphonaceae, Tilopteridaceae, Sphacelariaceae, Laminariaceae, Notheiaceae. The families marked with asterisks are described in the introductory section in some detail. The second part of the work is the detailed presentation of notes and drawings left by Kuckuck. The Ectocarpaceae are omitted. *Choristocarpus* of the Choristocarpaceae is described with propagulae and unilocular sporangia and zoospores, which were germinated in culture to plantlets which developed reproductive organs. *Discosporangium* Falk. is redescribed without original data. *Cutleria* Grev. is extensively discussed in its relation to peculiarities of life history, and original results of cultures presented. *Zanardinia* Nardo is described. **PHILIPPIA** (p. 19) (Elachistaceae) is described in detail based on *P.* **australis*** (*Elachista australis* J. Ag.) (p. 19). Details of structure and reproduction are given for 5 species of *Elachista*, including *E.* **neglecta*** (24), from the Adriatic. The structure of *Halothrix, Giraudia* and *Symphoricoccus* incl. *S.* **stellaris** (*Elachista stellaris* Aresch.) (p. 34) is described in detail and illustrated, and a few notes given on *Leptonema.* In the Corynophlaeaceae *Myriactis* is described in detail in several species, including *M.* **stellulata*** (*Elachista stellulata* Griff.) (p. 35), and *M.* **arabica*** (*Phacophila arabica* Kg.) (p. 39), *M.* **cystophorae*** (*Corynophlaea cystophorae* J. Ag.) (p. 40); *Corynophlaea* is described in structure and reproduction in 2 sp., incl. *C.* **crispa*** (*Leathesia crispa* Harv.) (p. 42); *Leathesia* and *Microcoryne* are described and illustrated. In the Mesogloeaceae *Eudesme* is described in 3 species, *Castagnea* is kept distinct and 8 species described, incl. *C.* **filum*** (*Mesogloea filum* Harv.) (p. 50), *C.* **vermicularis*** (*Bactrophora vermicularis* J. Ag.) (p. 51), *C.* **crassa** (*Mesogloea crassa* Sur.) (p. 52), and *C.* **posidoniae** (*Liebmannia posidoniae* Menegh.) (p. 52). *Mesogloea* incl. *M.* **reticulata** (*Liebmannia r.* B.) (p. 56) is described on the basis of 3 species (*Cladosiphon* in 2 species) as to structure and reproduction. *Chordaria* is described upon 3 species, including *C.* **chordaria*** (*Cladosiphon chordaria* Harv.) (p. 60) and *C.* **andersonii** (*Mesogloea andersonii* Farl.) (p. 61). **MYRIOGLOEACEAE** (p. 62) is offered as a new family based on **MYRIOGLOEA** Kck. (p. 63), with *Myriogloea* **sciurus** (*Myriocladia s.* Harv.) (p. 63), *Myriogloea* **chorda** (*Myriocladia c.* J. Ag.) (p. 63), and *Chordaria capensis* Kuetz. and *Mesogloea andersonii* Farlow provisionally referred to this genus though the actual transfer is not made. **MYRIOCLADIACEAE** (p. 63) is offered, based on the genus *Myriocladia,* of which the structure of 3 species is described, including *M. ekmani* (Aresch.) Kyl. **ACROTRICHACEAE** (p. 65) is offered based on *Acrothrix.* In the Spermatochnaceae *Spermatochnus* and *Stilophora* receive brief mention. The structure and reproduction of *Nemacystus* **decipiens** (*Cladosiphon d.* Suring.) (p. 68) is given at some length, and **STILOPSIS** (p. 70) n. gen., is offered based on *S.* **lejolisii*** (*Stilophora lejolisii* Thuret) (p. 70) but not defined by description. In Sporochnaceae, *Nereia* is described at length in morphogenesis and reproduction. In Splachnidiaceae *Splachnidium* is described at length. Of families Stictyosiphonaceae to Sorantheraceae incl., only a collection of illustrations was left, but these are reproduced. In Dictyosiphonaceae *Coilodesme* is described in detail in 3 species. Of the remaining families only illustrations of structure are given.—*Wm. Randolph Taylor.*

1980. **LUCAS, A. H. S. The marine algae hitherto recorded from north-east Australia.** *Rept. Great Barrier Reef Committee* 3: 47-57. 1931.—This list of Queensland algae is based upon both old and new records, and includes about 180 spp., with locality data.

1981. **MIGULA, W. Über einige japanische Characeen.** *Hedwigia* 70(3/4): 211-215. 1 fig. 1930.—An annotated list of species, with descriptions, including: *Nitella polyglochin* **f. japonica*** (p. 213), *N.* **dimorpha*** (p. 213), both Shihoku.

1982. **MOORE, CAROLINE S., and LAURA B. MOORE. Some desmids of the San Juan Islands.** *Publ. Puget Sound Biol. Sta.* 7: 289-336. 232 fig. 1930.—During the summer of 1929, 153 species belonging to 20 genera were found. These are figured, and keys are given for convenience in determining them.—*T. C. Frye.*

1983. **PASCHER, A. Beiträge zur allgemeinen Zellehre. I. Doppelzellige Flagellaten und Parallelentwicklungen zwischen Flagellaten und Algenschwärmern.** *Arch. Protistenk.* 68(2): 261-304. 21 fig. 1929.—First of a series dealing with multiplicity of cell forms. **DIDYMOCHRYSIS** based on *D.* **paradoxa*** (p. 262, 303), a Chrysomonad from fresh-water of Bohemia, resembles two *Ochromonas* cells joined laterally, with 2 pairs of flagella, 2 vacuolar systems, 2 chromatophores, and 2 anterior end zones, but a single nucleus. Other doubled forms are discussed, with theories of origin. A close parallelism of structure exists between certain of these

flagellates and certain algal swarm-spores, suggesting their close relationship.—*G. M. Robertson.*

1984. PASCHER, A. Eine neue braune Fadenalge des Süsswassers (Chrysophycee). *Arch. Protistenk.* 73(1): 60-72. 1 pl., 9 fig. 1931.—*Apistonema* **pyrenigerum*** (p. 71), a new filamentous form of Chrysophyceae, from Franzensbad, Bohemia, was found in a bed of *Cylindrospermum* growing near a spring-fed waterfall and moistened by the spray. The alga forms crooked filaments growing out from a basal mass of cells. Filament formation is marked in some groups, nearly absent in others. Two yellowish-brown chromatophores, provided with a pyrenoid, are present in each cell. Leucosin spherules or granules are present. Stages in the formation of swarm spores were observed, but the spores themselves were not seen. Stoppered cysts, characteristic of Chrysophyceae, were seen. The species is compared with *Apistonema commutatum* Pascher 1925 and a diagnosis is given of the genus and the two species.—*L. E. Noland.*

1985. SETCHELL, WILLIAM ALBERT. Hong Kong seaweeds, I. *Hong Kong Naturalist* 2(1): 39-60. 9 fig. 1931.—Directions for collecting and preserving are followed by general notes on various local spp.

1986. SHANNON, E. L., and L. C. ALTMANN. Growth in Codium mucronatum. *Publ. Puget Sound Biol. Sta.* 7: 391-392. 2 fig. 1930.—On the whole most of the growth takes place in the upper region. Growth farther down is unequal, some parts elongating much more than others.—*T. C. Frye.*

1987. SKVORTZOW, B. W. Notes on Ceylon diatoms. I. *Ceylon Jour. Sci. Sect. A, Bot., Ann. Roy. Bot. Gard. Peradeniya* 11(3): 251-260. 3 pl. 1930.—An annotated list of 99 spp., dimensions being given of each and brief descriptive notes of many. *Cerataulus thermalis* v. *sinensis* f. **ceylonica*** (p. 252); *Eunotia formica* v. **ceylonica*** (p. 253); *E.* **ceylonica*** (p. 253); *E. c.* var. **bigibba*** (p. 253); *E. frickei* v. **ceylonica*** (p. 253); *E.* **alstonii*** (p. 253); *Neidium affine* v. *genuina* f. **ceylonica*** (p. 254); *N. kozlowi* v. **ceylonica*** (p. 254); *Navicula pelliculosa* v. **ceylonica*** (p. 254); *N. digito-radiata* f. **ceylonica*** (p. 255); *N.* **ceylonica*** (p. 255); *N. perrotettii* f. **ceylonica*** (p. 255); *Stauroneis phoenicenteron* v. **ceylonica*** (p. 256); *Pinnularia divergens* v. *genuina* f. **ceylonica*** (p. 256); *P. subcapitata* v. **ceylonica*** (p. 256); *P. microstauron α eu-microstauron* v. *capitata* f. **ceylonica*** (p. 256); *P. m. β brebissonii* vars. **ceylonica*** and **recta*** (p. 256); *P. cardinaliculus* v. **ceylonica*** (p. 257); *Frustulia vulgaris* v. *asiatica* f. **ceylonica*** (p. 257); *F.* **ceylonica*** (p. 257); *Cymbella ventricosa* v. *laevis* f. **maxima*** (p. 258); *C. aequalis* v. *florentina* f. **ceylonica*** (p. 258); *Amphora turgida* v. **ceylonica*** (p. 258); *Surirella* **alstonii*** (p. 258); *S.* **ceylonica*** (p. 259).

1988. SKVORTZOW, B. W. Diatoms from Dalai-Nor Lake, eastern Mongolia. *Philippine Jour. Sci.* 41(1): 31-37. 2 pl. 1930.—Measurements are given for 61 forms, or spp., of which 25 forms are illustrated. *Scoliopleura* **pavlovi*** (p. 34); *Amphora ovalis* v. *pediculus* f. **mongolica*** (p. 34); *Surirella ovata* v. *ovata* fs. **mongolica*** and **curta*** (p. 36). Types in author's coll.

1989. SKVORTZOW, B. W. Alpine diatoms from Fukien Province, South China. *Philippine Jour. Sci.* 41 (1): 39-49. 3 pl. 1930.—Data from a collection made at Kuliang, Fukien, at 2400 ft. altitude. Measurements are given of 89 forms, or species, and illustrations of 31 forms. *Eunotia mayor* v. **asiatica*** (p. 40), Foochow and Hanka Lake, Primorsk Province, S.S.S.R.; *E. clever* v. **sinica*** (p. 40); *Achnanthes* **fukiensis*** (p. 41), *A. inflata* v. **sinica*** (p. 41); *Neidium kozlowi* v. **ceylonica*** (p. 41), Foochow and Ceylon; *Diploneis finnica* f. **sinica*** (p. 42); *Navicula* **fukiensis*** (p. 42), *N. lambda* v. **recta*** (p. 42), *N.* **chinensis*** (p. 42); *Pinnularia mesolepta* v. *angusta* f. **sinica*** (p. 43), *P. montana* v. **sinica*** (p. 42), *P.* **chinensis*** (p. 43); *Frustulia vulgaris* v. **constricta*** (p. 44); *Gomphonema puiggarianum* v. **sinica*** (p. 44), *G. sphaerophorum* v. **asiatica*** (p. 45); *Cymbella signata* v. **chinensis*** (p. 46); *Epithemia hyndmannii* v. **chinensis*** (p. 46); *Surirella* **fukiensis*** (p. 47), *S. saxonica* v. **sinica*** (p. 47). Types in author's coll.

1990. STOCKMANS, F. Contribution à l'étude de Gloeotaenium loitlesbergerianum Hansg. *Bull. Soc. Roy. Bot. Belgique* 62(2): 101-104. 4 fig. 1930.—This species of the Protococcaceae forms 2- and 4-celled colonies divided and capped by black bands which the author believes are not caused by gelatinization of the next to the outer layer of the wall, but by the presence of calcium carbonate in that portion of the wall, as indicated by microchemical tests.—*D. Doubt.*

1991. TANDY, G. Sundry observations on Caulerpa. *Proc. Linn. Soc. London No. 142.* 35: 1929/30(1931).—Abstract.

1992. VLK, WLADIMIR. Über die Struktur der Heterokontengeisseln. *Beih. Bot. Centralbl. 1 Abt.* 48 (1/2): 214-220. 15 fig. 1931.—Stained preparations (Löffler's method, as modified by Körner and Fischer) of *Botrydiopsis arhiza* and *Heterococcus* sp. show that the longer flagellum is a typical bilaterally ciliate "Flimmergeissel" and the shorter is a non-ciliated, simple, "Peitschengeissel," usually prolonged into a very slender terminal portion as in the Chrysophyceae. This indicates that the affinities of the Heterocontae are with the Chrysophyceae rather than with the Chlorophyceae.

1993. WANG, CHU-CHIA. Notes on some sub-aerial Myxophyceae of Nanking. *Nation. Central Univ. Sci. Repts.* [*Nanking*] *Ser. B.* 1(1): 59-64. 1 pl. 1930.—Annotated list of 17 forms.

1994. WANG, CHU-CHIA. The genera of freshwater algae in Nanking and Soochow. *Peking Soc. Nat. Hist. Bull.* 5(3): 27-32. 1931.—A preliminary list of genera found in China: 55 genera of Isokontae, 2 Heterokontae, 2 Chrysophyceae, 20 Bacillariales, 1 Cryptophyceae, 3 Dinophyceae, 4 Euglenineae, 1 Rhodophyceae, 31 Myxophyceae, and 2 Charales.

FUNGI

1995. BROCQ-ROUSSEU. Sur le développement du cryptocoque de la lymphangite épizootique. *Bull. Acad. Vét. France* 3(3): 150-153. 1930.—Previous experimental work is discussed, the author concluding from his own microscopical work that *Cryptococcus farciminosus* is not reproduced by budding. He points out that earlier descriptions are due to an illusion caused by adhesion of 2 elements of unequal thickness, kept in place by fixation, and massive staining not permitting clear vision of details. In his numerous observations, the author has never seen a single budding *Cryptococcus;* in those that appear to be such, there is no continuity of the enveloping membranes of parent and daughter cells. The free forms of Henry were observed from mere points to fully developed cryptococci, thus presenting the full development of the parasite. The author believes the *Cryptococcus* to be a flattened form which, in the preparations, is never seen from the poles. 2 methods of cryptogenesis are presented as possible: (1) reproduction such as that of *Plasmopara viticola,* which emits motile zoospores which lose their mobility and develop a membrane, or (2) reproduction by means of spores as in *Mycoderma immitis.*

1996. **CLEMENTS, F. C., and C. L. SHEAR.** The Genera of Fungi. i-iv, +496p., 58 pl. The H. W. Wilson Co.: New York, 1931. Pr. $8.00.—This is a revised and much enlarged illustrated edition of Clement's The Genera of Fungi. The book introduction (19 pages) discusses the various criteria used and principles of classification and nomenclature. This is followed by dichotomous keys to the classes, orders, families and genera of the fungi described previous to 1929 so far as they could be located. Myxomycetes and bacteria have been omitted. Following the keys is a list of types and synonyms in which each genus either treated as valid or as a synonym is assigned a type species, the attempt being made to select a type species which is fairly well known and representative of the genus as at present generally applied. Citation of the place of publication and of location in Saccardo's Sylloge Fungorum or other taxonomic work is given. A bibliography covering 18 pages gives most of the important taxonomic works on the fungi, especially the more recent. This is followed by a glossary of 30 pages. The following new genera are proposed by Clements, their type species being the species mentioned. Endomycetaceae: **OLEINIS,** *O.* lateralis (v. Tiegh.) Clem. (p. 245). Gymnoascaceae: **MYRILLIUM,** *M.* myriosporus (Rostr.) Clem. (p. 246). Eurotiaceae: **CAROTHECIS,** *C.* palearum (Richon) Clem. (p. 247). Hypocreaceae: **PROLISEA,** *P.* exiguella (Nyl.) Clem. (p. 282); **PRONECTRIA,** *P.* lichenicola (Ces.) Clem. (p. 282); **PERICOCCIS,** *P.* leptogicola (C. & M.) Clem. (p. 283). Lophiostomaceae: **BYSSOLOPHIS,** *B.* byssiseda (Flag. & Chen.) Clem. (p. 286). Verrucariaceae: **LICHENYLLIUM** [also indicated as in Collemaceae], *L.* lojkanum (Hue) Clem. (p. 287). Microthyriaceae: **MICROTHYRIS,** *M.* maculans (Zopf) Clem. (p. 302); **TRYBLIS,** *T.* arnoldi (Rehm) Clem. (p. 312). Collemaceae: **COLLEMIS,** *C.* rupestris (L.) Clem. (p. 316). Phomaceae: **PHOMYCES,** *P.* meliolicola (Speg.) Clem. (p. 359); **DARLUCIS,** *D.* longiseta (Henn.) Clem. (p. 364); **DIPLODINIS,** *D.* rostrupi (Vestg.) Clem. (p. 364). The following new names are proposed by Clements: Endomycetaceae: **ENDYLIUM** (*Magnusiomyces* Zand.) (p. 245). Saccharomycetaceae: **ISOMYCES** (*Debaryomyces* Kloeck.) (p. 245); **THELIS** (*Hanseniospora* Zikes) (p. 246); **ZONOSPORIS** (*Schwanniomyces* Kloeck.) (p. 246). Eurotiaceae: **PHAEIDIUM** (*Laaseomyces* Ruhl) (p. 248). Perisporiaceae: **DICHAETIS** (*Wentiomyces* Koord.) (p. 250). Capnodiaceae: **CHAETOBOTRYS** (*Kusanobotrys* Henn.) (p. 253); **CHAETYLLIS** (*Raciborskiomyces* Siem.) (p. 253); **DYSRHYNCHIS** (*Henningsomyces* Sacc.) (p. 253); **CHAETOMERIS** (*Treubiomyces* Hoehn.) (p. 254). Sphaeriaceae: **CERILLUM** (*Colletomanginia* Har. & Pat.) (p. 262). Dothideaceae: **DIDOTHIS** (*Uleodothis* T. & S.) (p. 291); **DOTHOPHAEIS** (*Englerodothis* T. & S.) (p. 291). Tuberculariaceae: **CHAETOSIRA** (*Wiesneriomyces* Koord.) (p. 403). Tuberculariaceae: **CYLOMYCES** (*Listeromyces* Penz. and Sacc.) (p. 404).—*C. L. Shear.*

1997. **DIETEL, P. Unterklasse: Hemibasidii (Ustilaginales und Uredinales).** In: **A. ENGLER und K. PRANTL. Die natürlichen Pflanzenfamilien nebst ihren Gattungen und wichtigeren Arten insbesondere den Nutzflanzen.** 2nd ed., edited by **A. ENGLER.** Bd. 6, Abt.: **Eumycetes (Fungi), Klasse: Basidiomycetes,** by **P. CLAUSSEN.** vii+98p. 80 fig. Wilhelm Engelmann: Leipzig, 1928.—The work follows the plan of the 1st edition, including discussions of all genera recognized as valid by the authors, with illustrations of many of the spp. The following new combinations of names of rusts are found: *Bubakia* **stratosa** (Cke.) (p. 48), *B.* **glochidii** (Syd.) (p. 48), *B.* **brideliae** (Koord.) (p. 48), *Cerotelium* **malvicolum** (Speg.) (p. 57), *C.* **butleri** (Syd.) (p. 57), *Trachyspora* **wurthii** (Ed. Fisch.) (p. 57), *Spirechina* **cundinamarcensis** (Mayor) (p. 60), *S.* **variabilis** (Mayor) (p. 60), *S.* **chinensis** Diet. (p. 60), *Prospodium* **von gunteni** (Mayor) (=*Puccinia*) (p. 65), *Nyssopsora* **cedrelae** (Hori) (p. 70), *Haploravenelia* **arizonica** (Ell. & Tracy) (p. 72), *H.* **minima** (Cke.) (p. 72). *H.* **pygmaea** (Lagerh. & Diet.) (p. 72), *H.* **ornata** (Syd.) (p. 72), *H.* **appendiculata** (Lagerh. & Diet.) (p. 72), *H.* **natalensis** (Syd. & Evans) (p. 72), and *Eriosporangium* **aecidiiforme** (Thum.) (p. 79).—*E. K. Cash.*

1998. **DODGE, CARROLL W.** The higher Plectascales. *Ann. Mycologici* 27(3/4): 145-184. 2 pl., 2 fig. 1929.—A taxonomic treatment of the 2 families, Trichocomaceae and the Elaphomycetaceae, which constitute the so-called higher Plectascales. The Elaphomycetaceae include the genera *Mesophellia* (5 spp.) and *Elaphomyces* (24 spp.). *Elaphomyces* **verrucosus** (p. 171); *E. asperulus* v. **rugosus** (*E. rugosus* Fries) (p. 178). **MESOPHELLIEAE** (p. 152) is a new tribe. Keys to the spp. are presented together with a complete description of each sp. and lists of material examined.—*J. A. Stevenson.*

1999. **DOIDGE, E. M., and H. SYDOW.** The South African species of the Meliolineae. *Bothalia* 2(2): 424-472. 1928.—Distribution of Meliolineae in So. Africa corresponds to that of the indigenous timber forests. The geographical range of the species is coincident with that of the host plants. The family Meliolineae is revised with the genus *Appendiculella* reunited with *Irene*, and *Irenopsis* with *Meliola*. A key to the genera is followed by a description of each. *Irene* and *Meliola* have keys to the spp. with descriptions of 13 new spp. and 1 new combination. The descriptive formulae are those used by Beeli and revised by Stevens. *Irene* **nuxiae** Syd. (p. 433; 463), on *Nuxia floribunda* Benth. and *N. tomentosa* Sond., N. Transvaal; *Meliola* **scolopiae** Doidge (p. 437; 467), on *Scolopia zeyheri* Warb, Transvaal; *M.* **brachyodonta** Syd. (p. 442; 464), on *Rhus tomentosa*, Transvaal; *M.* **allophyllii** Doidge (p. 443; 463), on *Allophyllus erosus* Radkl., Cape Province; *M.* **behniae** Syd. (p. 444; 464), on *Behnia reticulata* F. Dedrichs, N. Transvaal; *M.* **azimae** Doidge (p. 450; 464), on *Azima tetracantha*, Cape Province; *M.* **indigoferae** Syd. (p. 451; 466), on *Indigofera natalensis* and *Baphia racemosa*, Natal and Durban; *M.* **buxicola** Doidge (p. 452; 465), on *Buxus macowani* Olio, East London; *M.* **cnestidis** Doidge (p. 453; 465), on *Cnestis natalensis*, Cape Province and Natal; *M.* **doidgeae** Syd. (p. 457; 465), on *Sapindus oblongifolius* Sond., Transvaal; *M.* **dactylipoda** Syd. (p. 460; 463), on *Cryptocarya woodii* Engl. and *C. liebertiana*, Duncairn and Rhodesia; *M.* **goniomae** Doidge (*Amazonia g.* Doidge) (p. 461), on *Gonioma kamassi* E. Mey., Transvaal; *M.* **osyridis** Doidge (p. 462; 466), on *Osyris compressa* A. DC. and *Rhoiocarpus capensis* A. DC.; *M.* **littoralis** Syd. (p. 462; 466), on *Burchellia capensis, Gardenia rothmannia, G. globosa, Grumilea capensis, G. cymosa, Keetia transvaalensis, Pavetta bowkeri, Plectronia ciliata, P. spinosa* and *P.* spp. Transvaal. Latin description of the new spp. is followed by a host index by families, a host index by genera and an alphabetical index of genera and spp. Types are in the National Herbarium.—*L. Angst.*

2000. **DOWDING, E. SILVER.** The sexuality of the normal, giant, and dwarf spores of Pleurage anserina (Ces.) Kuntze. *Ann. Bot.* [*London*] 45(177): 1-14. 1 pl. 10 fig. 1931.—*P. anserina* is one of the Pyrenomycetes which normally has 4 spores in each ascus. In addition to normal spores, the asci occasionally produce giant spores or dwarf spores. Usually a giant spore replaces 2 normal spores, but sometimes 2 giant spores occur in the same ascus and replace 3 normal spores. The dwarf spores occur in the asci only in pairs, and each pair replaces a single normal spore. The spores germinate freely and the mycelium grows vigorously on sterilized horse-dung. A mycelium derived from a single normal spore fruits readily. Normal spores are binucleate and bisexual. A mycelium derived from a single giant spore fruits readily. Giant spores are bisexual. When a giant spore replaces 2 normal spores, it probably contains 4 nuclei. A mycelium derived from a single dwarf spore remains sterile. Mating experiments have shown that the mycelia derived from individual dwarf spores fall into 2 groups which may be called (+) and (−). When 2 (+) mycelia or 2 (−) mycelia are paired, no perithecia are produced; but when a (+) mycelium and a (−)

mycelium are paired, abundant perithecia are developed in a band where the 2 mycelia have come into contact. A dwarf spore is uninucleate and unisexual. When 2 monosporous mycelia, each derived from a member of a pair of dwarf spores, are paired, they fruit readily when they come into contact with one another (one exception to this rule observed). Usually, in each pair of dwarf spores one spore is of 1 sex, (+), and the other is of the opposite sex, (−).—*Author's summary.*

2001. **FAULL, J. H. The morphology, biology, and phylogeny of the Pucciniastreae.** *Proc. Internat. Congress Plant Sci., Ithaca, New York, 1926.* 2: 1735-1745. 1929.—Cultural and morphological studies were made by the author and several of his students on 24 spp. of the Pucciniastreae, distributed among the 8 known genera of this sub-family. Complete life cycles were worked out for 13 of them, of which the following were made for the first time: *Milesina marginalis* Faull and Watson, *M. Kriegeriana* Magn., *M. polypodophila* (Bell) Faull, and *Uredinopsis Atkinsonii* Magn. Several hitherto unreported stages are recorded: Stages O, I of *Pucciniastrum epilobii* (Pers.) Otth. on *Abies balsamea;* O, I of *Hyalopsora aspidiotus* (Peck) Magn. on *A. balsamea;* O, I of *Milesina kriegeriana* Magn. on *A. balsamea;* II, III of *M. kriegeriana* on *Aspidium spinulosum* in America; O, I of *M. marginalis* Faull and Watson on *Abies balsamea;* III of *M. marginalis* on *Aspidium marginale;* O, I, II, III of *M. polypodophila* (Bell) Faull., on *Abies balsamea* and *Polypodium vulgare;* O, I, II, III of *Uredinopsis atkinsonii* Magn. on *Abies balsamea* and *Asplenium felix-femina.* The spermogonia are morphologically distinctive for the genera and to some extent for individual spp. The time periods between inoculation and emergence of the peridermia are a means of distinguishing between certain closely allied spp.—for example, 15-20 days for *Pucciniastrum abieti-chamaenerii* and 23-32 days for *P. epilobii.* All uredinia possess a peridium. The uredospores bud off singly from a basal cell and are not catenulate. The teliospores of all spp. are produced in relation to the epidermis. In *Uredinopsis* they form a loose crust under the epidermis and are not scattered throughout the mesophyll. The results of 69 sets of culture experiments are presented, a large number of which are new. Phylogenetically the Pucciniastreae are regarded as primitive rusts, with the white-spored forms near the base of the evolutionary complex, and such genera as *Calyptospora* and *Melampsoridium* among the more recent.—*J. H. Faull.*

2002. **GILBERT, E. J. La mycologie sur le terrain: méthodes, buts, résultats.** 183p., Librairie E. Le Francois: Paris, 1928.—A plea for the application of ecology to the study of the higher fungi. Fungus habitats are analyzed with reference to the various factors affecting them. Edaphic factors regarded as important are the physical and chemical nature of the soil, the effect of the amount of humus present and its source, and the yearly and seasonal supply of moisture and its relation to evaporation. Climatic factors considered are heat, wind, rain, seasons, light and local climates with their variations. While these are all treated much as in the ecology of the higher plants, special reference is made throughout to the fungus flora. Major topographic influences, such as latitude and altitude, are regarded as of comparatively subordinate importance so far as the fungi are concerned, their greatest influence being an indirect one due to their marked effect on the phanerogamic vegetation. In proof of this is cited the marked similarity often noted between the fungus floras of regions widely separated geographically. Biotic factors influence not only parasites and such pseudosaprophytes as wood rotting forms and mycorrhizal fungi, but saprophytes also. Changes due to succession of higher plants in a given area are reflected in the succession of fungi. Lists of fungi characteristic of various ecological formations, e.g., of coniferous and of various types of deciduous forests, are given. The ecological amplitude is defined as the range of all variables within which active life is possible for any fungus species. The more factors concerned, the narrower the limits will be. On basis of preceding considerations a tentative ecological classification of fungi is presented, as follows: I. Saprophytes: A. humicoles (1. humicoles proper, 2. fimicoles), B. terrestres (1. hypogaei, 2. epigaei), C. epixyles; II. Pseudoparasites: 1. wound parasites, 2. mycorrhizal fungi, 3. facultative root parasites; III. Parasites: 1. obligate root parasites, 2. true parasites. The location where a fungus is growing (station) is, then, not a mere geographic locality but a unified habitat and must be clearly defined as such in field notes, which should give full details as to regularity and time of appearance, abundance and areal restriction as well as the details of habit and mycelial characters. The species itself must be an abstraction centering about a norm, the specific type, but permitting considerable variation within limits difficult to define. Failure to realize this has caused many ecological variations to be described incorrectly as species.—*G. W. Martin.*

2003. **HORNE, A. S., and S. N. DAS GUPTA. Studies in the genera Cytosporina, Phomopsis, and Diaporthe. 1. On the occurrence of an "ever-saltating" strain in Diaporthe.** *Ann. Bot.* [*London*] 43(171): 417-435. 7 fig. 1929.—*D. perniciosa* isolated from apples gave rise to an "ever-saltating" strain. The saltation was cyclic. Temp. influenced saltation only indirectly, as it influenced growth rate. The influence of nutritive conditions on saltation "seemed to be correlated not with the nature of the constituents themselves, but with the altered acidity of the medium."—*J. A. Small.*

2005. **ITO, SEIYA. On some new ascigerous stages of the species of Helminthosporium parasitic on cereals.** *Proc. Imp. Acad.* [*Tokyo*] 6(8): 352-355. 1930.—*Ophiobolus* **setariae** (Saw.) Ito et Kuribayashi (*Helminthosporium s.* Saw.) (p. 352); *Pyrenophora* **graminea** Rabh.) Ito et Kurib. (*H. gramineum* Rabh.) (p. 353); *P.* **japonica** Ito et Kurib. (p. 353), on *Hordeum sativum* Jess. (common and naked barley); *P.* **avenae** (Eidam) Ito et Kurib. (*H. avenae* Eid.) (p. 354). All the perfect stages above were obtained in culture, not in the field. Analytical keys are given separating these and the other ascigerous stages of *Helminthosporium* earlier described by Ito and by Drechsler. In agreement with Nishikado (1928), who divided *Helminthosporium* into the 2 subgenera *Fuso-Helminthosporium* and *Cylindro-Helminthosporium,* based on the morphology, and the mode of germination of the conidia, the author recognizes distinctions between the corresponding perfect stages,

and proposes the genus **DRECHSLERA** for the spp. referred by Nishikado to his subgen. *Cylindro-Helminthosporium*, thus replacing the name, *Cylindro-Helminthosporium*, deemed improper and too long. *Drechslera* **arundinis** (*H. a.* Lev.), *D.* **catenaria** (*H. catenarium* Drechs.), *D.* **gigantea** (*H. giganteum* Heald and Wolf), *D.* **tritici-vulgaris** (*H. t.* Nish.). The conidial stages of *Pyrenophora graminea, P. teres, P. japonica, P. avenae, P. bromi,* and *P. tritici-repentis,* are also referred to *Drechslera.* (All p. 355).

2006. KALLENBACH, FRANZ. Die Röhrlinge (Boletaceae). In: *Die Pilze Mitteleuropas* 1(10): 61-68. 3 pl. (2 col.) 1930.—*Boletus porphyrosporus** Fr. and *Boletinus cavipes** (ex Opat.) Kalchbr. are treated; synonymy, diagnoses, detailed description, ecology, distribution, and literature are given.

2007. KARLING, J. S. Studies in the Chytridiales IV. A further study of Diplophlyctis intestina (Schenk) Schroeter. *Amer. Jour. Bot.* 17(8): 770-778. 6 pl. 1930.—The zoospores of *D. intestina* germinate shortly after coming to rest by the formation of a fine penetration tube which, after passing through host cell wall, differentiates very soon into a rhizoidal and globular portion. The latter part develops into the zoosporangium. The apophysis develops somewhat subsequently between the incipient zoosporangium and the point of origin of the rhizoids. Zoospores may germinate readily in situ. They may thus form zoosporangia and resting spores inside of the old sporangium. The typical zoosporangium has 1 neck, but under certain conditions as many as 8 may develop.—*J. S. Karling.*

2008. LOUNSBURY, JAMES A. Investigations on the nature of Protoachlya paradoxa Coker. *Trans. Wisconsin Acad. Sci. Arts & Lett.* 25: 215-225. 2 fig. 1930.—In the interest of testing the generic characters of *Protoachlya paradoxa,* a large number of clones of this fungus were developed under many different conditions. No treatment which permitted typical zoospore formation and discharge showed any influence on the disposition of the zoospores after their escape. Sex organ formation, hitherto reported not to yield to the usual stimuli for oogonial and antheridial development, was obtained by growing the clones well out of contact with the air. Some observations on anaerobic tolerance are reported.—*J. A. Lounsbury.*

2012. NISIKADO, YOSIKAZU. Studies on the Helminthosporium diseases of Gramineae in Japan. *Ber. Ohara. Inst. Landw. Forsch. Japan* 4(1): 111-126. 9 pl. 1929; Original publication, in Japanese, in: *"Tokubetu-Hokoku" Ohara Inst. Agric. Res.,* pp. 1-14, pp. 1-384. Dec., 1928.—This paper includes investigations of 24 spp. of *Helminthosporium* parasitic on 8 spp. of cereals and 18 spp. of wild grasses. Seven types of symptoms are used in classification: leaf stripe, leaf or eye spot, net blotch, foot rot, sooty heads, and black knots. Identification of spp. is based on inoculation tests and host range. *Helminthosporium* is divided into 2 subgenera, **EU-HELMINTHOSPORIUM** (p. 123) and **CYLINDRO-HELMINTHOSPORIUM** (p. 125). A key to the spp. is given. *Pyrenophora* (or *Pleospora*) and *Ophiobolus* (or *Ophiochaeta*) are known as the ascigerous stages of *Helminthosporium.* The author adds to the known list *Ophiobolus kusanoi* Nisikado on *Eragrostis major.* The ascigerous stage in all known spp. of *Eu-Helminthosporium* falls in genus *Ophiobolus; Cylindro-Helminthosporium* has perfect stages of the *Pyrenophora* type. Temp. limitations of conidial germination and growth and pH concentration ranges are used in distinguishing spp. The *Helminthosporium* spp. attacking cereals include *H. oryzae* Breda de Haan causing sesame leaf spot of rice, *H. gramineum* Rab. causing stripe disease of barley, *H. teres* Sacc. causing net blotch of barley, *H. sativum* P. K. & B. causing spot blotch of barley, and foot rot of wheat, *H. tritici-vulgaris* Nisikado causing yellow spot of wheat, *H. avenae* Eidam causing leaf blight of oats, *H. maydis* Nisikado and Miyake causing leaf spot of maize, *H. setariae* Sawada causing leaf spot of millet, *H.* **panici-miliacei*** (p. 120) causing leaf blight of millet, and *H.* **yamadai*** (p. 120) causing leaf spot of millet. *Helminthosporium* spp. attacking grasses include *H. tritici-repentis* Diedicke on *Agropyrum semicostatum, H. arundinis* Lev. on *Arundo donax, H. catenarium* Drechs. on *Beckmannia erucaeformis, H.* **brizae*** (p. 121) on *Briza minor, H.* **coicis*** (p. 121) on *Coix lacryma jobi, H. nodulosum* (B. et C.) 2015. SASS, JOHN E. The cytological basis for homothallism and heterothallism in the Agaricaceae. *Amer. Jour. Bot.* 16(9): 663-701. 4 pl., 6 fig. 1929.—The common 4-spored forms of *Coprinus ephemerus* and *Galera tenera* are diploid and heterothallic. Karyogamy occurs in the basidium; in *C. ephemerus* mating reactions of monosporous mycelia indicate 2 sex classes. In these 2 spp. and in *Naucoria semiorbicularis, Hygrophorus borealis* var. *subborealis, Collybia cirrhata* and *Stropharia umbonatescens,* there occur forms with 2-spored basidia. The following forms are described: *Coprinus ephemerus* f. **bisporus** (p. 669), *Galera tenera* f. **bispora** (p. 682), *Naucoria semiorbicularis* f. **bispora** (p. 680). These are diploid and normally homothallic. Karyogamy and 2 nuclear divisions occur in the basidia and each spore may receive 2 nuclei. Occasional spores produce mycelia with permanently uninucleate cells. These primary mycelia react as haplonts, producing clamp-bearing mycelia, which in the case of *C. ephemerus* f. *bisporus* produce fruit bodies in culture. Mating reactions of the aberrant haplonts suggest the possibility of many "sex classes," of which only a few combinations react. The aberrant haplonts are the result of occasional spores receiving but 1 nucleus.—*J. E. Sass.*

2016. SEAVER, FRED JAY. The North American cup-fungi. (Operculates.) 284p. 46 pl. (2 col.). 15 fig. Publ. by author: New York, 1928.—The present work is a monographic revision of the "section" Operculates (comprising Pezizaceae and Elvellaceae) of the Pezizales. An introductory chapter presents the general features of the group: its phylogeny, morphology, life history, ecology, etc., considerable emphasis being laid on the manner of dehiscence of the ascus, the correlation of the operculate and inoperculate character with their morphological characters, and the position of the ascostome. The author points out that the genera with eccentric ascostome generally have large, fusoid, usually striate spores, and are typically tropical. Numerous keys are provided, leading from the order Pezizales down to the species. Each family, tribe, genus, and species is described. For each species, synonymy, type locality, and distribution is given, and illustrations, if any exist, are cited. Pezizaceae; *Sphaerospora* perplexa (p. 45), New York; *S.* monilifera (*Peziza m.* Berk. & Curt) (p. 47); *Sphaerosoma* hesperium* (*Ruhlandiella hesperia* Setchell) (p. 51); *Boudiera* echinulata* (*Sphaerosoma echinulatum* Seaver) (p. 52); *Lamprospora* macrantha (*L. crec'hqueraultii* var. *m.* Boud.) 2017. SOLHEIM, WILHELM GERHARD. Morphological studies of the genus Cercospora. *Illinois Biol. Monogr.* 12(1): 1-84. 4 pl.. 1929.—The author proposes to do away with color as a primary taxonomic character in the classification of the Hyphomycetes. The families Moniliaceae and Dematiaceae are therefore united, and *Cercosporella* and *Cercosporina* added to *Cercospora. Didymaria* is emended so as to include all forms having clavate conidia born on conidiophores of the Cercospora type, as represented in the type species. A group of characters has been selected which is tentatively proposed as a basis for classifying the genus *Cercospora.* Included are *C.* **carotae** (*C. apii* Fres. var. *carotae* Pass.) (p. 43), *C.* **pastinacina** (*Cercosporella pastinacae* Karst.) (p. 45), *Cercospora* **lobeliaecola** (*Cercospora effusa* (B. & C.) Ell., in part) (p. 64), *Didymaria* **effusa,** (*Cladosporium effusum* B. & C.) (p. 65). A host index for *Cercospora* and *Didymaria* spp. is appended.—*W. G. Solheim.*

2018. SPRING, DOROTHY. A comparison of seven strains of organisms causing human blastomycosis. *Jour. Infect. Dis.* 44(3): 169-185. 5 fig. 1929.—Six strains were similar in their morphology in test-tube and hanging drop, but the 7th approached *Scopulariopsis* and was far less pathogenic for animals. The mouse and rat were the most susceptible; generalization rarely occurred except in mice. Crystal violet, brilliant green and gentian violet had strongest inhibiting power in culture in the order named; concentrations of 1:10,000 were frequently necessary to inhibit absolutely. Four commercial brands of gentian violet had equal powers as inhibiting agents. Intra-testicular inoculation of pus has no advantage diagnostically over culture in test-tubes. Six strains were comparatively resistant to 42°C, contrasting with the majority of dermatophytic fungi, which are generally susceptible.—*F. D. Weidman.*

2019. STEVENS, F. L. Parasitic fungi of British Guiana, Trinidad and Costa Rica. *Ann. Mycologici.* 28 (5/6): 364-371. 1 fig. 1930.—An annotated list of 3 Phycomycetes, 2 Basidiomycetes, 12 Ascomycetes, and 21 Fungi Imperfecti. Ascomycetes: *Schizothyrium bambusellum* var. **magnum** (p. 364), British Guiana, on *Bambusa;* **ANTENNELLOPSIS** Mendoza (p. 365), similar to *Antennella* and *Antennellina,* type *A.* **mangiferae** Mendoza (p. 365), British Guiana, on *Mangifera indica;* **SCORIADOPSIS** Mendoza (p. 365), closely associated with a *Meliola,* and resembling *Scorias,* based on *S.* **miconiae** (p. 365), Br. Guiana, on *Miconia* sp.; **PARASCORIAS** Mendoza (p. 366), resembling *Scorias,* type *P.* **byrsonimae** Mendoza (p. 366), Br. Guiana, on *Byrsonima* sp.; **DORATOSPORA** Mendoza (p. 366), near *Parodiopsis milioloides* (Wint.) Arn., type *D.* **guianensis** Mendoza (p. 366), Br. Guiana, on *Alchornea cordata; Guignardia* **ingae** (p. 367), Costa Rica, on *Inga* sp.; *Physalospora* **quadraspora*** Stevens and Solheim (p. 367), Costa Rica, on *Commelina* sp. Fungi Imperfecti: *Phyllosticta pithecolobii* var. **machaerii** Stevens and Solheim (p. 368), Trinidad, on *Machaerium* sp.; *Harknessia* **mauritiae** (p. 369), Br. Guiana, on *Mauritia;* **BECCOPYCNIDIUM** (p. 369), near *Sphaerographium* and *Cornularia,* type *B.* **palmicolum** (p. 369), Br. Guiana, on Palmae; *Colletotrichum* **toluiferae** Stevens and Solheim (p. 370), Trinidad, on *Toluifera* sp.; *C.* **catenulatum** (p. 370), Br. Guiana, on *Agave angustifolia marginata; Tuberculariа* **nigra** (p. 371), Br. Guiana, on *Eupatorium* sp.

2020. SYDOW, H. Novae fungorum species. XX. *Ann. Mycologici* 28(5/6): 432-447. 1930.—**SORATAEA** (p. 432), Uredinales, probably related to *Blastospora* and perhaps to *Maravalia,* based on *S.* **amiciae** (p. 432), II and III, on *Amicia lobbiana* Benth, Bolivia; *Uncinula* **peruviana** (p. 433), on *Tecoma grandiceps,* Peru; **XENOSTIGME** (p. 434-435), Ascomycetes [apparently incertae sedis] based on *X.* **trichophila** (p. 434), on *Luehea divaricata* Mart., Paraguay; **PACHYSACCA** (p. 435) [Dothideales ?] resembling *Oligostroma,* based on *P.* **eucalypti** (p. 435), on *Eucalyptus rostrata* Schlecht., So. Australia; *Phomachora* **eucalypti** (p. 437), the imperfect stage of *Pachysacca eucalypti* (p. 437); *Dasyscypha* **trichophila** (p. 438), on *Olearia moschata* Hook. f., New Zealand; **POLYDISCINA** (p. 439), Discomycetes, [incertae sedis ?], based on *P.* **boliviana** (p. 439), on Combretaceae, probably *Terminalia* or *Buchenavia,* Bolivia; *Phlyctaeniella* **cryptica** (p. 441), parasitic in the perithecia of an undetermined Ascomycete on *Eucalyptus obliqua* L'Herit., So. Australia; *Oothecium* **consimile** (p. 443), on *Trema guineensis,* Sierra Leone; *Colletotrichum* **atriplicinum** (p. 444), on *Atriplex patulus,* Germany; *Cercospora* **polymera** (p. 445), on *Cremastus (Bignonia) sceptrum,* Brazil; and *Cercospora* **protensa** (p. 446), on *Amorphophallus campanulatus,* Philippine Islands.

2021. VALKANOV, ALEXANDER. Protistenstudien. 5. Hyphochytrium hydrodictii, ein neuer Algenpilz. *Arch. Protistenkunde* 67(1): 122-127. 11 fig. 1929.—*Hyphochytrium* **hydrodictii***, parasitic only in young cells of *Hydrodictyon reticulatum* near Sofia. Development of sporangium precedes that of mycelia. Method of sporulation was not observed, but is considered to be via a terminal split.—*G. M. Robertson.*

2022. VERWOERD, LEN, and B. J. DIPPENAAR. Descriptions of some new species of South African fungi and of species not previously recorded from South Africa. *So. African Jour. Sci. 27:* 326-330. 1930.—*Puccinia phyllocladiae* Cke., I and III, on *Asparagus sarmentosa; Cercospora* **oliniae** (p. 326), on *Olinia cymosa; Septoria* **knowltoniae** (p. 327), Gordon Bay (Cape Province), on *Knowltonia vesicatoria; Cladosporium* **baccae** (p. 327), on ripe grapes, causing a berry rot; *Diplodia* **monsteraе** (p. 327), on *Monstera deliciosa; Pestalotia* **watsoniae** (p. 327), on *Watsonia rosea* var. *alba; Coccochora* **lebeckiae** (p. 328), on *Lebeckia candolleana,* this being first record of *C.* from So. Africa; *Puccinia polycampta* Sydow, I, II, III, on *Anthericum hispidum,* I being described for the first time; *Pleospora dianthi* de Not., on *Dianthus caryophyllinus,* new for So. Africa, and considered to be the ascigerous stage of *Septoria dianthi,* Desm.; *Mycosphaerella pinodes* (Berk. and Blox.) Stone, on *Pisum sativum,* associated with *Ascochyta,* believed to be the first record of *M. p.* from South Africa. Types are apparently in the herb. of the senior author, and n. spp. from Stellenbosch, Cape Province, unless otherwise stated.

2023. WESTON, WILLIAM H., Jr. Observations on Loramyces, an undescribed aquatic Ascomycete. *Mycologia* [*New York*] 21(2): 55-76. 2 pl. 1929.—A previously undescribed perithecial ascomycete found growing on softened culms of *Juncus militaris* Bigelow submerged from a few inches to 3 ft. in fresh water ponds on Nashawena and Naushan Islands, Massachusetts, is described.

The morphology, reproduction and peculiarities in structure, discharge, distribution, attachment and germination of the spores in their conformity to the aquatic form of life are considered. The fungus is distinctive and is established as a new genus **LORAMYCES** (p. 72) (Sphaeriaceae) and species *L. juncicola* (p. 72).—*E. M. Mrak.*

2024. **WILENCZYK, A. Formation des asques dans les cultures de Trichophyton.** [**Ascus production in Trichophyton cultures.**] *Compt. Rend. Soc. Biol.* 98(1): 70. 1 fig. 1928.—Asci contained 4 rose-colored spores.

MYXOMYCETES

2025. **HOWARD, FRANK L. The life history of Physarum polycephalum.** *Amer. Jour. Bot.* 18(2): 116-133. 8 pl., 1 fig. 1931.—At germination the nucleus of the spore divides once mitotically. Each daughter cell, after a quiescent period following emergence from the spore case, puts out an anterior flagellum and becomes first an amoeboid swarmcell and then changes shortly to a comma-shaped rotating one. Motile swarmcells function as isogametes which fuse posteriorly in pairs to form zygotes. It is believed that after nuclear fusion and division of the fusion nucleus the plasmodial stage is initiated, although a complete series of steps is lacking. The macroscopic plasmodium is mycophagous. It may be slowly dried and the resulting sclerotium reactivated by placing it under moist aerobic conditions. The plasmodium is transformed into sporangia only at night, the process requiring about 12 hrs. for completion. The change of the open plasmodium to a continuous verrucose layer, subsequent segmentation of this layer and formation of knobs, followed by vertical pillars and a successively dichotomously lobing sporangial head, are followed in detail. Capillitium formation is by secretion and not by protoplasmic disintegration and it is completed before mitotic division. The capillitium is at first badhamoid and then becomes differentiated into lime-filled nodes and limeless internodes. Nuclei of 2 types may be distinguished: larger, lightly stained ones which undergo mitotic division, and smaller, densely stained ones which disintegrate. Cytokinesis occurs concurrently with the mitotic nuclear division preceding spore formation. A single nuclear division, requiring about 30 min. for completion, takes place. Following final cleavage of the protoplasm into uniformly hexagonal, uninucleate masses, a continuous intersporal membrane is formed in the furrows. This membrane splits to form the spore walls. After splitting, the walls pull apart and the spores become spherical. During this pulling apart, irregularities become visible on the adjoining surfaces which develop into the minute spinules on the mature spore wall.—*F. A. Gilbert.*

LICHENES

2026. **ANDERS, JOS. Erklärungen zu den Icones von F. Arnold.** *Beih. Bot. Centralbl. Abt. 2.* 45(3): 541-562. 1929.—In connection with his extensive lichen exsiccati, Arnold issued (in 1859-1899, under the title "Icones") photographs of critical spp. and forms of *Cladonia.* The nomenclature used in labeling many of these illustrations is scarcely possible to understand without the aid of his "Lichenologische Fragmente," publications now very difficult to obtain. The author here presents new explanations for the "Icones" Nos. 1263-1356, 1412-1463, 1484-1496, 1636-1643, and 1674-1684, giving the synonymy according to modern *Cladonia* studies. Finally, the spp. and forms are arranged in order so as to reveal the systematic relationships more clearly.—*B. B. Higgins.*

2027. **CHOISY, M. La morphologie du genre Cladonia, Lichen discomycite.** *Bull. Soc. Mycol. France* 45: 184-188. 1929.—A response to Prof. Moreau, opposing the conception of podetia as soredial structures and maintaining Wainio's idea of regarding them as stipes.—*M. Choisy* (*transl. by F. A. Wolf*).

2028. **DU RIETZ, G. EINAR. The discovery of an Arctic element in the lichen-flora of New Zealand and its plant-geographical consequences.** *Rept. Australasian Assoc. Advanc. Sci.* 19: 628-635. 1928 (1929).—During the author's visit to New Zealand in 1926-27, a great number of lichens identical with or at least very nearly related to Arctic spp. were found in the high mountains. Some of these (e.g., *Alectoria nigricans*) are found nowhere else in the Southern Hemisphere; others (e.g., *Cornicularia aculeata*), are found also in the Magellanic region; and in some (e.g., *Cetraria islandica*) this Magellanic distribution area is connected with the Boreal one by a series of localities along the Andes. On the other hand, lichens are known which have a distribution-area connecting New Zealand with the Magellanic region by a series of localities in the Antarctic (e.g., *Usnea antarctica*). Thus it appears very probable that the road along the Andes and across the Antarctic may have been used in the tertiary period by the Arctic lichens now found in both So. America and in New Zealand, but not in the mountains of the Malayan region.—*G. E. Du Rietz.*

2029. **MOREAU. Les lichens. Morphologie, Biologie, Systématique. Vol. III. Encyclopédie Biologique.** [**Lichens. Morphology, Biology and Taxonomy. Vol. III.**] 148p. 2 pl., 65 fig. Paul Lechevalier: Paris, 1929. Pr. 30 fr.

Gard.; *Amblystegium juratzkanum* v. **giganteum** (*A. serpens* var. *g.* Grout) (p. 69); *A. varium* v. **parvulum** (*A. serpens radicale p.* Aust.) (p. 70); *Leskea* **montanae** (*Amblystegium m.* Bryhn) (p. 75); *Campylium polygamum* v. **minus** (*Hypnum p.* var. *m.* Schimp.) (p. 83); *C. p.* var. **longinerve** (*H. p. l.* R. & C.) (p. 84); *Hygrohypnum palustre* v. **ehlei** (*Amblystegium e.* Arnell) (p. 88); *H.* **norvegicum** (*Limnobium n.* Br. & Sch.) (p. 92); *H.* **novae-caesareae** (*Hypnum n.-c.* Aust.) (p. 94); *Calliergon giganteum* v. **cyclophyllotum** (*Hypnum c.* Holzinger) (p. 97); *C. sarmentosum* v. **beringianum** (*Hypnum s.* var. *b.* Card. & Thér.) (p. 98); *Calliergidium pseudostramineum* v. **plesistramineum** (*Hypnum plesistramineum* Ren.) (p. 101); *Calliergonella* **schreberi** (*Hypnum s.* Willd.) (p. 103); *Drepanocladus revolvens* v. **miquelonensis** (*Hypnum scorpioides miquelonense* Ren.) (p. 107); *Hypnum sinuolatum* Kindb. and *H. subsecundum* Kindb., synonyms of *Campylium chrysophyllum* (Brid.) Bryhn; *H. decursivulum* C. M. & Kindb., syn. of *Campylium radicale* (P. B.) Grout; *H. krausei* C. Muell., syn. of *Hygrohypnum alpestre* (Sw., Hedw.) Loeske; *Calliergon subgiganteum* Kindb., a syn. for *C. richardsoni* (Mitt.) Kindb.; *Hypnum hyperboreum* Bryhn is merely a starved alpine form of *Calliergon sarmentosum* (Walenb.) Kindb. Attention is called to the development of a long excurrent costa in aquatic forms of *Hygroamblystegium, Cratoneuron* and *Drepanocladus* as parallel developments due to a similar habitat. Attention is further called to the fact that this development is more frequent in habitats where lime is abundant. —*A. J. Grout.*

2037. HERZOG, TH. Hepaticae Philippinenses a cl. C. J. Baker lectae. *Ann. Bryologici* **4**: 79-94. 4 fig. 1931.—An annotated list: *Hymenophytum malaccense; Plagiochila* **radians** (p. 80); the probable invalidity of the section *Cucullatae* of *Plagiochila* is commented on; *Lepidozia* **biloba*** (p. 83); *Blepharostoma setigerum,* hitherto known only from Java; *Psiloclada clandestina,* new for the Philippines; *Trichocolea* **fragillima** (p. 84); *Archilejeunea serricalyx,* new for Philippines; *Ptychanthus* **bidentatus** ♀ (p. 85); *Thysananthus* **furcatus*** ♀ (p. 87); *T.* **aculeatus*** (p. 89); *Caudalejeunea* **bakeri*** (p. 90); *Drepanolejeunea riddleana,* new for Philippines; *D. dactylophora* v. **submuricata** (p. 92); *D. bakeri* Herzog, diagnosis emended on discovery of a fertile plant; *Leptolejeunea spathulifolia* St., emended; *Leptocolea karstenii* v. **cristulata** (p. 94).

2038. LUISIER, A. Les mousses de l'Archipel de Madère et en général des îles Atlantiques. *Brotéria, Sér. Bot.* **24**(1): 18-47; (2); 66-96; (3): 119-140; 4 fig. [Contd. from 23(3): 145. 1927. *Cf. Biol. Absts.* 4(3): 9516. 1930. To be contd.] 1930.—Continues the annotated list of species and secondary forms, including genera from *Campylopus* to *Orthotrichum* inclusive. New are *Campylopus* **dixoni*** (p. 20), *Fissidens* **barretoi** Dix. & Luis. (p. 42), *Grimmia* **winteri** (*Schistidium canariense* Winter) (p. 127), *G. trichophylla* ssp. **azorica** (*G. a.* Ren. & Card.) (p. 129). *Campylopus polytrichoides* v. **flavescens** f. **epilosa** (p. 25) also appears to be new.—*A. LeRoy Andrews.*

2039. MENGE, FRIEDRICH. Die Entwicklung der Keimpflanzen von Marchantia polymorpha L. und Plagiochasma rupestre (Forster) Stephani. *Flora* **24**(4): 423-478. 5 pl., 7 fig. 1930.—I. *Marchantia polymorpha.* Spores are easily germinated on agar with nutrient salts. The speed of development is largely dependent on the age of the spore, temp., light intensity, concentration of nutrient salts. The growth processes of individual examples were followed. The short protonema gives rise to a cell-plate which after a 2-angled apical cell cuts off 5 to 7 segments which may continue to divide. The apical sinus moves along in the region of the apical cell or its segments, and the thallus may become many-layered before the apical notch is formed. After 3 or 4 weeks the thallus forks. Tissue differentiation even after 30 days is very slight; formation of air chambers occurs later. II. *Plagiochasma rupestre.* The spores germinate easily on agar and on a silica-jelly base with nutrient salts, in about 11 days after sowing. The few-celled germ-tube develops toward the light. By quadrant divisions the apical cell forms a germ disc which lies perpendicular to the direction of the germ-tube and of the light rays. In one of the quadrants a 2-angled apical cell is formed, which cuts off a maximum of 3 or 4 segments alternately to the right and left which divide further. The germling from the germ-disc stage on is a cell-body. Perpendicular observations from above afford in many cases no adequate view of the developmental courses, so that this method of observation has had limited success. The apical cell cuts off one or more segments above and below. These secondary apical cells appear to become formed at a stage in which the primary apical cell is longitudinally divided. Already in the very young thallus the air chambers appear in the form of intercellular clefts which appear in part regularly along the oldest walls and which very soon, because they are always flat, escape attention. They do not attain the height of differentiation of the air chambers of the mature thallus.—*J. W. Gillespie.*

2040. PEARSON, W. H. Notes on a collection of Hepaticae from Jamaica. *Ann. Bryologici* **4**: 95-112. 2 pl. 1931.—Material collected by F. O. Bower in 1909, at an alt. of 4000-5000 ft., was studied. Among the 26 spp. listed are: *Jubula piligera* v. **jamaicensis*** (p. 96), the 1st record for *Jubula* from the West Indies; *Trachylejeunea* **jamaicensis*** (p. 98); *Ceratolejeunea* **mollis*** (p. 99); *Taxilejeunea* **langiana*** (p. 102); *Radula* **jamaicensis*** (p. 103); *Cephaloziella* **secundifolia*** (p. 106); *Cephalozia* **densa*** (p. 108); *Plagiochila* **cinchoniensis*** (p. 110); *Aplozia* **boweri*** (p. 111). Lengthy notes are given on *Platylejeunea* **vincentina*** (Gottsche) Spr., *Trichocolea tomentosa* (Sw.), and *Lophocolea coadunata** (Sw.).

2041. STEERE, WILLIAM CAMPBELL. Notes on the mosses of southern Michigan. *Bryologist* **34**(1): 1-5. 1931.—The list contains 18 spp. not before recorded for the state.—*A. M. Taylor.*

2042. THOMPSON, A. New Vice-County records for North Country mosses. *Jour. Bot.* [*London*] **69**(822): 162-164. 1931.—24 species and varieties are recorded.—*A. L. Grant.*

Mens. 12): 209-216. 1928. —An annotated list of 18 forms including *Hymenophyllum* **humbertii** (p. 209), *Hemitelia* **humbertiana** (p. 210), *Asplenium pachysorum* f. **simplex** (p. 211), *Blechnum* **ivohibense** (p. 211), *Doryopteris* **latiloba** (p. 213), *Polypodium myosuroides* Sw. (p. 214), notes, *P.* **excaudatum** (*P. decorum* var. *e.* Bonaparte) (p. 215), *P.* **humbertii** (p. 215), *Aneimia* **madagascariensis** (p. 216).

2045. **CLARK, JOSEPHINE F. Ferns of the Red River country, Maine.** *Rhodora* 32(379): 133-136. 1930.—List of species collected, including *Botrychium lanceolatum* (Gmel.) Ångstroem and *Woodsia alpina* (Bolton) S. F. Gray, both new to Maine.—*S. F. Blake.*

2046. **COPELAND, E. B. Pteridophytes collected for the Arnold Arboretum on Vanikoro, Santa Cruz Islands, by S. F. Kajewski.** *Jour. Arnold Arboretum* 12(1): 46-49. 1931.—Thirty-two numbers of Pteridophytes were collected on Vanikoro Island, including: *Cyathea* **veitchii** (*Alsophila v.* Baker) (p. 46), *Oleandra* **angusta** (p. 47), *Lindsaya* **kajewskii** (p. 47), *Lycopodium* **kajewskii** and *L.* **vanikorense** (p. 48).—*A. Rehder.*

2047. **FERNALD, M. L. Some varieties of the amphigean species of Osmunda.** *Rhodora* 32(376): 71-76. 1930. (*Contrib. Gray Herb.* 87(5)).—*Osmunda cinnamomea* vars. **typica** (p. 75) (eastern N. Amer.) and **asiatica** (p. 75) (Amur. (type) to Japan). *O. regalis* is represented in eastern N. Amer. by var. *spectabilis* (Willd.) Gray; *O. claytoniana* in the Himalayas by var. *vestita* (Wall.) Milde. The Brazilian record of *O. claytoniana* is expunged. The form of *O. cinnamomea* in tropical and subtropical eastern Amer. is var. *imbricata* (Kunze) Milde.—*S. F. Blake.*

2048. **JACKSON, R. T. An exceptionally large Onoclea sensibilis.** *Rhodora* 32(383): 225-226. 1930.—Records a sterile frond 51¼ inches long, the blade being 19½ in. long. In a note, the editors record a frond 65¾ in. long.—*S. F. Blake.*

2049. **[MEIER, K. I.] МЕЙЕР, К. И. Развитие спорангия в Psilotum triquetrum Sw. [Development of the sporangium in P. triquetrum.]** [French résumé.] *Bull. Soc. Nat. Moscou, Sect. Biol.* (Бюллетень Московского Общества Испытателей Природы, Отд. Биол.) 37(1/2): 52-64. 16 fig. 1928.

2050. **PICKETT, F. L. Notes on xerophytic ferns.** *Amer. Fern Jour.* 21(2): 49-57. 1931.—A summary of the author's work on the life histories of xerophytic ferns. The prothallia are extremely resistant to drought; 5% of one culture were alive after 5 years of complete desiccation in the laboratory. If the cells in any portion of a prothallium survive, they will grow and produce one or more new prothallia when given favorable conditions. Available evidence indicates that laboratory experiments give an accurate idea of what happens in nature. Spore dispersal in *Cheilanthes gracillima* is described.—*C. A. Weatherby.*

2051. **RUIZ de AZUA, J. Equisetos de la provincia de Alava.** *Bol. R. Soc. Españ. Hist. Nat.* 31(3): 201-210. 10 fig. 1931.—Descriptive list of 23 forms of *Equisetum,* with especial notes on the anatomical characters of *E. arvense* var. *pseudo-silvaticum* and *E. pratense.*—*C. A. Weatherby.*

2052. **SYLVÉN, N. Dryopteris robertiana (Hoffm.) C. Chr. funnen i Västergötland. [D. robertiana in Västergötland, Sweden.]** *Bot. Notiser* 1930(5): 409. 1930.—Specimens found by the author at Kinnekulle in 1911 are the only record for this part of Sweden.—*H. K. Svenson.*

GENERAL

2053. **SCHELLENBERG, G. Beiträge zu einem phylogenetischen System der Blütenpflanzen.** *Beibl. Vierteljahrschr. Naturforsch. Ges. Zürich* 73(15): 358-381. 1928. —A theoretical paper. It is suggested that tristichous foliation might be looked upon as primitive, as it is easily derived from the foliation resulting from growth with a trigonous initial cell. As ancestral characters are strongly retained in the fertile region, flowers with trimerous cycles should be considered primitive, i.e., the Ranales (incl. Piperales) and the Monocotyledones. Spiral arrangement of floral organs would be a progressive development due to torsions in the initial region; but this would have been soon abandoned as it does not lead to zygomorphy and adaption to restricted orders of insects. Entomogamy is thought primitive, at least in angiosperms, as anemogany needs special adaption of the stigma, the tip of the megasporophyll, and as such adaptions must be progressive. Monochlamydeae cannot be primitive, as suggested in the systems of Engler and of Wettstein, because they are anemogamous, because their ovary is syncarpous, because they show a great variety of reductions in the ovary (e.g., sterile locules, few or but 1 ovule, often fewer ovules than carpels), and because in many forms the ovary is inferior. The Coniferales cannot be the ancestors of angiosperms, for when the evolution of the latter began, the former were already an ancient group and because it is very unlikely that "giant forms" like conifers should be able to give rise to a quite novel group. Bennettitales also cannot be the ancestors, for their ovary has become "syncarpous" by the bracts whilst the megasporophylls are highly reduced, and in angiosperms the very megasporophylls build up the ovary. Caytoniales roll up their megasporophylls from the tip, angiosperms from the midrib. Evidently the ancestors of angiosperms are not known; they were very likely small herbaceous plants hardly preserved as fossils. From such points of view monocotyledons with their primitive venation, axes without secondary growth, and tristichous foliation throughout can be looked upon as the first angiosperms (and among them the Alismataceae), from which the Ranales would derive as the most primitive group of dicotyledons.—*G. Schellenberg.*

ANGIOSPERMAE (MIXED)

2054. **CHIOVENDA, E. La collezione botanica di S. A. R. il Duca degli Abruzzi alla sorgente dell'Uebi Scebeli. [The botanical collection made by the Duke of the Abruzzi at the source of the Webi Shebeli, Abyssinia.]** *Nuovo Giorn. Bot. Ital.* 36(3): 360-371. 1929.—The trees, grasses and Leguminosae typical of the region are listed, with notes. The presence of the following shows extended distribution: *Delphinium ruspolii, Polygala mat-*

teiana, Cienfuegosia ellenbeckii, Pistacia lentiscus var. **falcatula** (nomen nudum), *Indigofera garckeana, Rubus scioanus, Pimpinella volkensii, Anthriscus keniensis, Vernonia antinoriana, Galinsoga parviflora, Artemisia afra, Berkheya spekeana, Sideroxylon oxyacantha, Sweertia centianifolia, Ipomoea chrysosperma, Micromeria ellenbeckii, Otostegia modesta, Euphorbia glochidiata, Barbeya oleoides* and *Lagarosiphon steudneri*. The following are new to science: *Crotalaria* **hypargyrea** (p. 363); *Trifolium* **basileianum**, *Terminalia* **basilei**, *Combretum* **sublancifolium**, *Cucumis* **lævigatus**, *Pimpinella* **arussorum**, (all on p. 364); *Peucedanum* **mattirolii**, *Vernonia* **heterocarpa**, *Artemisia afra* v. **arussorum**, *Lobelia* **scebelii**, (all on p. 365); *Jasminum* **basilei**, *Sweertia* **mattirolii**, *S.* **tischeri**, **SABAUDIELLA** (Hildebrandtieae), with *S.* **aloysii** as type, (all on p. 366); *Ipomoea obscura* v. **aurea**, *Discopodium penninervium* v. **magnifolia**, *Thunbergia paulitschkeana* v. **lanceolata**, *Barleria* **subinermis**, *B.* **tischeriana**, *B.* **pannosa**, (all on p. 367); *Justicia* **leucoclada**, *Premna* **neurophylla**, *Coleus* **microtrichus**, (all p. 368); *Salvia* **macrorrhiza**, *Lasiocorys stachydiformis* vars. **argentata** and **scioana**, *L. abyssinica* v. **brachycalyx**, *Tinnaea* **somalensis** Gürke, (all on p. 369); *Euphorbia* **impressa**, *Barbeya oleoides* v. **arussorum**, *Kniphofia* **aloysii-sabaudii**, *Chlorophytum* **ducis-aprutii**, (all p. 370); *Commelina* **phaeochaeta**, *Latipes senegalensis* v. **tuberculatus**, *Sporobolus* **pseudobiflora**, *Ioannegria* **brizoides**, (all on p. 371).

2055. **MAKINO, TOMITARÔ. A contribution to the knowledge of the flora of Japan.** (Continuation and to be contd.) *Jour. Popov (p. 27), to include *A. nobilis* and other spp.; *A. pamiralaicus* Lipsky, emended description; *A.* **pseudonobilis** M. Popov (p. 30); *A. rubromarginatus* v. **oeroilanicus** (*A. o.* M. Pop.) (p. 31); *A. r.* var. *o.* f. **confertus** (*A. o.* var. *c.* M. Pop.) (p. 31); *A. severtzovii* v. **orbiculatus** M. Popov (p. 32); *Astragalus,* sect. **ALBERTOREGELIA** M. Popov (p. 35), to include *A. tschimganicus* and *A. albertoregelia; A. variegatus* v. *typicus* M. Popov (p. 38); *A. v.* var. **koksuensis** M. Popov (p. 38); *A.* **xipholobus** M. Popov (p. 39); *A. zeravschanicus* Lipsky (=*A. marguzaricus* Lipsky); *A.* **babatagi** M. Popov (p. 41); *A.* **densus** M. Popov (p. 42) (not formally described); *A. bucharicus* Rgl., emended description; *A. commixtus* v. **abbreviatus** M. Popov (p. 44); *A. stenocystis* Bge. and *A. aschuturi* B. Fedtsch. are removed from the synonymy of *A. cyrtobasis* Bge.; *A. excedens* M. Pop. & M. Kult., emended description; *A. filicaulis* ssp. **rytilobus** M. Popov (*A. r.* Bge.) (p. 48); *A. leiosemius* M. Popov (*A. lasiosemius* var. *leiosemius* Lipsky) (p. 50); *A. managildensis* B. Fedtsch., emended description; *A. megalomerus* v. **typicus** M. Popov (p. 52); *A. m.* var. **simplicifolius** M. Popov (p. 52); *A.* **xanthomeloides** Eug. Kor. & M. Popov (p. 57); *Amaranthus blitoides,* recorded as new to Asia; *Zygophyllum* **dielsianum** M. Popov (p. 75); *Viola* **alaica** Vvedensky n. sp. (=*V. turkestanica* var. *rupestris* Komar.) (p. 79); *Morina kokanica* Rgl., emended description; *Spergularia diandra* v. **leiosperma** M. Popov (*Lepigonum salsugineum* var. *leiospermum* Bge.) (p. 95); *Silene noctiflora* v. **dolichopetala** M. Popov (*Melandryum noctiflorum* var. *dolichopetalum* Zapal.) (p. 98); *S. ovalifolia* M. Popov (*Melandryum ovalifolium* Rgl. & Schmalh.) (p. 99), emended description; *S. trajectorum* v. **typica** M. Popov (p. 100); *S. t.* var. **schischkinii** M. Popov (p. 99); *S. t.* var. **pseudotenuis** M. Popov (*S. p.* Schisch.) (p. 100); *Pyrethrum* **santoanum** H. Krasch., M. Pop., & Vved. (*Chrysanthemum* **santoanum** K., P. & V.) (p. 102); *Cousinia* **glauciifolia** M. Kultiassov (p. 103); *C.* **pseudaffinis** (p. 105) with vars. typica (p. 105) and **bucharica** (p. 105), all by M. Kult.; *C.* **rosea** M. Kult. (p. 105); *C.* **syrdarjensis** M. Kult. (p. 106); *Jurinea* **grumosa** M. Iljin (p. 107); *Jurinea lasiopoda* f. **integrifolia** Iljin (p. 108); *Centaurea* **lasiopoda** M. Popov & M. Kultiassov (p. 110); *C.* **vvedenskyi** M. Popov (p. 111); *Astragalus* **neo-lipskyanus** M. Popov (*A. lipskyanus* M. Popov, not Freyn) (p. 113). All forms are from Turkestan. Keys are given to certain groups of spp.

MONOCOTYLEDONES

2062. BECHERER, A. Zur Nomenklatur zweier Gramineen. *Rep. Spec. Nov. Reg. Veg.* 26(7/15): 231-232. 1929.—The name *Oplismenus undulatifolius* (Ard.) was first adequately published by Roemer and Schultes (1817) and not in 1812 by Palisot de Beauvois (nomen nudum). But *Hierochloe odorata* (L.) Pal. was validly published by Palisot in 1812.

2063. FLAKSBERGER, C. Eutriticum verschiedener Länder in Herbarien und Kollektionen von Deutschland, Österreich, Frankreich, Dänemark und Schweden. *Rep. Spec. Nov. Reg. Veg.* 27(734/740; paper 14): 167-178. 1929; (741/750; paper 24): 241-253. 1930.—Notes are given on the collections from various regions of the earth, Abyssinia, Egypt, Libyan Desert, etc., covering all the continents. For each region there are notes on the chief collectors, species represented, and especially on variations within the species. The following are new: *Triticum thaoudar* vars. **reuteri** and **balansae** (without locality), and from Asia Minor vars. **bornmülleri, haussknechtii,** and presumably **fuscum** Zhuk. (all p. 174); *T. aegilopoides* f. **breviata** (p. 242), Greece; *T. a.* var. **pseudo-boeoticum** (p. 243), Serbia; *T.* **monococcum** v. **hohensteinii** (p. 249), Germany. Of the 5000 specimens of wheat examined, approximately 3700 are without data as to natural origin. Field specimens seem in general to have been collected with a view to peculiar forms; those planted in gardens have as a rule little data on geographic origin, since they have been raised from a purely systematic viewpoint. In Körnicke's Handbuch many vars. of wheat are based on color of the spike. Here great confusion occurs, since it is almost impossible to identify colors which fade in age, and which moreover appear differently to various observers. Some of the described color varieties themselves have varying color forms, and a biochemical analysis of the pigments would seem to be the only method for clear-cut differentiation. Additional new varieties based on garden material are: *T. polonicum* vars. **heidelbergi** (p. 252) and **gracile** (p. 252); *T. dicoccum* v. **subliguliforme** (p. 252) (coll. Schulz); *T. turgidum* v. **sublinnaeanum** and v. **false-jodurum** (p. 252).—*H. K. Svenson.*

2064. GUILLAUMIN, A. Les "Phalaenopsis" hybrids issus de "P. amabilis." *Arch. Mus. Hist. Nat.* [*Paris*] 4: 33-36. 2 col. pl. 1929.—Enumeration of hybrids with consideration to combined characteristics of parents from a genetical viewpoint.—*A. Guillaumin* (*transl.*).

2065. SMITH, C. A. Scilla lanceaefolia of the flora Capensis. *Kew Bull. Misc. Inform.* 1930(6): 241-252. 1930.—Introductory remarks showing confused state of synonymy arising from transferring *Lachenalia lanceaefolia* Jacq. to *Drimia lanceaefolia* by Gawler. *Scilla* **guttata** (*S. lanceaefolia* Baker) (p. 243); *S.* **doratophylla** (*S. lanceolata* Baker non Viviani) (p. 245); *S.* **ovalifolia** (*Drimia o.* Schrad.) (p. 245); *S.* **cicatricosa** (*S. lanceaefolia* Wood non Baker) (p. 246); *S. livida* Baker (=*Lachenalia lanceaefolia* Red.); *S. maculata* Schrank, with full original description; *S.* **inquinata** (p. 248), Transvaal; *S.* **climacocarpha** (p. 249), Orange Free State; *S.* **apertiflora** (*Drimia a.* Baker =*S. lorata* Baker) (p. 250); *S. ensifolia* (Ecklon) Britten (=*S. ludwigii* Baker). Several new identifications are given for specimens previously referred to *"S. lanceaefolia"* in literature. —*C. A. Smith.*

2066. STOUT, A. B. [Notes on Hemerocallis species.] *Addisonia* 14(2): 17-32. 8 col. pl. 1929.—Contains botanical descriptions and discussions of horticultural uses with colored plates of 8 daylilies: *Hemerocallis flava* L., *H. minor* Mill., *H. thunbergii* Baker, *H. fulva* clon **maculata** (*H. f.* var. *maculata* Baroni) (p. 23), *H. aurantiaca* Baker, *H. dumortierii* Morren, *H. middendorffii* Traut. & Mey., and *H.* **multiflora** (p. 31), China.—*A. B. Stout.*

2067. STRANSKI, Iv. T. Triticum monococcum and T. dicoccum in Bulgaria. [In Bulgarian with German translation.] *Bull. Soc. Bot. Bulgarie* 3: 171-276. 1929.—This is a study of the distribution, varieties, quality of seed, and culture of *T. monococcum* and *T. dicoccum.* Of the wild-growing *T. monococcum* the author describes the following varieties of the subspecies *aegilopoides: boeoticum* Boiss., *zuccariori* Flaksb., **bulgaricum** (p. 202; 255). Of the cultivated *T. monococcum* in Bulgaria are known varieties: *hornemanni* Clem., *laetissimum* Körn., *flavescens* Körn., *eredvianum* Zhuk. (with a new form **punctata** (p. 210; 260), *tauricum* Drosd., *symphaeropolitanum* Drosd. (with new forms **parallelicum** and **patulum** Stranski (both p. 218; 261)), *vulgare* Körn., *atriaristatum* Flaksb., *nigricultum* Flaksb., and **sofianum** (p. 208; 258) (with forms **densiuscula** and **laxiuscula** (both p. 209; 259)). There are fewer forms of *T. dicoccum* Schrank in Bulgaria, namely: var. *farrum* Bayle-Barelle (forma *volgense* Flaksb. and forma *tatarica* Stol.) and *rufum* Schübler (forma *maturatum* Flaksb.). —*I. Kovachevsky.*

2068. SUMMERHAYES, V. S., and C. E. HUBBARD. A supplement to the grasses of the Fiji Islands. *Kew Bull. Misc. Inform.* 1930(6): 252-265. 1930.—Enu-

merates 63 grasses collected by J. D. Tothill in Fiji, including: *Ischaemum* **vitiense** (p. 264); *Eriochloa* **procera** (*E. ramosa* O. Ktze.) (p. 256); *Paspalum orbiculare* v. **cartilagineum** (*P. c.* Presl) (p. 257); and *Setaria* **pallidifusca** (*S. glauca* Summerh. & Hubb. not Beauv.) (p. 259).—*A. D. Cotton.*

2069. SVENSON, H. K. Monographic studies in the genus Eleocharis. *Rhodora* 31(367): 121-135; (368): 152-163; (369): 167-191; (370): 199-219; (371) 224-242. 4 pl. 1929.—(*Contrib. Gray Herb. 86.*) A brief review of the classification of *Eleocharis* is followed by a conspectus of the 11 series recognized, only the first 5 of which are included in this paper. The species of each series are treated separately, with keys, descriptions, synonymy, citation of exsiccatae, critical notes, lists of doubtful species, and discussion of geographical distribution. Altogether 56 species are fully treated, and about half as many more mentioned among the doubtful species. The achenes of nearly all the species are illustrated and there are habit drawings of many. *Eleocharis equisetoides* (Ell.) Torr., ranging from Massachusetts to Florida and Texas, is separated from *E. interstincta* (Vahl) R. & S. of Texas, the West Indies, and southward. The name *E. parvula* (R. & S.) Link is adopted for *Scirpus nanus* Spreng. The following are new: *E.* **philippinensis*** (p. 155), Luzon; *E.* **plicarhachis*** (*Scirpus p.* Griseb.) (p. 158); *E. pauciflora* v. **suksdorfiana** (*E. s.* Beauv.) (p. 174), var. **bernardina** (*Scirpus bernardinus* Munz & Johnston) (p. 174); *E.* **leptos*** (*Isolepis leptos* Steud.) (p. 176), var. **coloradoensis** (*Scirpus coloradoensis* Britton) (p. 176), var. **johnstonii** (p. 177), California; *E.* **boliviana*** Palla (p. 179), Bolivia; *E. acicularis* (L.) R. & S. var. **typica** (p. 184), f. **inundata** (p. 186), "the common submersed form", f. **fluitans** (*E. acicularis* b. *fluitans* Doell) (p. 186), f. **rigidula** (*Scirpus acicularis* var. *rigidula* Reichb.) (p. 187), f. **triangularis** (*Heleocharis triangularis* Reinsch) (p. 187), var. **submersa** (*Scirpus acicularis β submersa* Hj. Nilss.) (p. 188), var. **longiseta** (p. 189), eastern Asia, var. **occidentalis** (p. 190), western United States and northern Mexico, var. **gracilescens** (p. 191), Tennessee, Oklahoma, California; ***E. lindheimeri** (*E. acicularis* var. *lindheimeri* C. B. Clarke) (p. 199); *E.* **brachycarpa*** (p. 200) Mexico; *E.* **bella*** (*E. acicularis* var. *bella* Piper) (p. 201); *E.* **reverchonii*** (p. 203) western Texas; *E.* **nervata*** (p. 204) Mexico; *E.* **stenocarpa*** (p. 205) Colombia, Venezuela; *E. engelmanni* forma **detonsa** (*E. e.* var. *detonsa* Gray) (p. 208), var. **monticola** (*E. monticola* Fernald) (p. 209), var. *monticola* forma **leviseta** (*E. monticola* var. *leviseta* Fernald) (p. 210); *E. obtusa* var. **peasei** (p. 217) Quebec to New Hampshire; var. **ellipsoidalis** Fernald (p. 218) Massachusetts to Virginia; *E.* **galapagensis** (p. 233) Chatham I., Galapagos, *E.* **alveolata** (p. 241) Cuba, Brazil.—*S. F. Blake.*

DICOTYLEDONES

2070. BECKER, W. Euphrasia tatarica Fischer var. coquoziana var. nov. *Rep. Spec. Nov. Reg. Veg.* 24(4/13): 203-204. 1927.—This variety (p. 203) is described from Switzerland. The partially glabrous form is termed f. **glabrescens**, the wholly glabrous form is described as f. **glabra** (p. 204), Italy.

2071. BLAKE, S. F. A. A new Polygala from Colombia and Bolivia. *Proc. Biol. Soc. Washington* 43: 5-6. 1930.—*Polygala* **macerrima** (p. 5), type from Colombia.

2072. DAHLSTEDT, H. Über einige orientalische Taraxacum-Arten. *Acta Horti Bergiani* 9: 1-56. 15 fig. 1 col. pl. 1929.—Most of the following new species were grown in the botanical garden at Upsala, from seeds collected by G. Samuelsson in Greece. Extensive herbarium material from Sweden, Germany and Austria was also examined. In the group *Scariosa* Hand.-Mazzetti emend. Dahlst.: *T.* **apollinis*** (p. 4), *T.* **graecum*** (p. 6), *T.* **delphicum*** (p. 9), *T.* **hellenicum*** (p. 11), *T.* **aleppicum*** (p. 14), Greece and Asia Minor; *T.* **scolopendrinum*** (p. 19), and *T.* **sintenisii*** (p. 21), Mesopotamia. The group *Erythrocarpa* Hand.-Mazzetti emend. Dahlst. is divided into: *Euerythrocarpa* Dahlst., containing *T. calocephalum** Hand.-Maz. emend. Dahlst. and *T.* **poliochlorum*** (p. 26); and *Erythrosperma* Dahlst., containing *T.* **parnassicum*** (p. 29) and *T.* **gracilens*** (p. 30). Of uncertain position is *T.* **lobulatum*** Bornm. & Dahlst. (p. 32), Persia and Turkestan. Unless otherwise stated, the locality is Greece. The text figures contain illustrations of leaves; the colored plate has 53 fig. showing involucres, single flowers, and achenes.

2073. DINTER, K. Index der aus Deutsch-Südwestafrika bis zum Jahre 1917 bekannt gewordenen Pflanzenarten. *Rep. Spec. Nov. Reg. Veg.* 23(18/25): 363-371. 1927. 24(14/21): 302-304; (22/25): 366-368. 1928. 25(4/6): 49-51; (14/22): 209-210. 1928.—Entries 2384-2708, including: *Stachys* **karasmontana** (p. 365) [nomen nudum]; *Stapelia* **ausana** Dtr. & Brgr. (p. 365); *Striga* **chloroleuca** Dtr. [nomen subnudum] (p. 367); *Talinum* **crispatulum** (p. 369); 24(14/21): *Tripteris* **integrifolia** (p. 303); *Tryphostemma* **harmsianum** (p. 304); 24 (22/25): *Utricularia* **monophylla** (p. 367); *Vangueria* **lateritia** (p. 367). 25(4/6) covers entries 2638-2677; 25 (14/22) covers entries 2678-2708. Where not otherwise indicated, the above names would appear to be published by a brief German comment.

2074. FRIES, ROB. E. Zwei neue Anonaceen. *Rep. Spec. Nov. Reg. Veg.* 24(14/21): 246-248. 1928.—*Uvaria* **caroti-afzelii** [sic] (p. 246), Madagascar; *U.* **buchtienii** (p. 247), Bolivia.

2075. HANDEL-MAZZETTI, H. A revision of the Chinese species of Lysimachia, with a new system of the whole genus. *Notes Roy. Bot. Gard. Edinburgh* 16 (77): 51-122. 1928.—A reevaluation of the whole genus on the primary basis of floral structure leading to the consideration of the genus as the most primitive of the Primulaceae. A key to the 83 Chinese species is followed by a systematic enumeration of all (147) the species with critical notes particularly of those in China. The species are grouped in 5 subgenera: *Idiophyton* (1 sp.), *Eulysimachia* (including *Steironema*) (90 spp.), *Palladia* (46 spp.), *Naumburgia* (1 sp.), and *Lysimachiopsis* (9 spp.). The following appear: *L.* **solanoides** (p. 70); *L.* **grandiflora** (*L. ramosa* var. *g.* Franch.) (p. 71); *L.* **pseudotrichopoda** (p. 71); *L.* **cordifolia** (p. 76); *L.* **stellarioides** (p. 78); *L.* **membranacea** (*Steironema membranaceum* Greene) (p. 80); *L.* **greeneana** (*Steironema pumilum* Greene not Lys.) (p. 80); *L.* **validula** (*Steironema validulum* Greene) (p. 80); *L.* **longipedicellata** (*Steironema longipedicellatum* Lun.) (p. 80); *L.* **lunellii** (*Steironema l.* Greene) (p. 80); *L.* **verticillata** (*Steironema verticillatum* Greene) (p. 80); *L.* **graminea** (*Steironema gramineum* Greene) (p. 80); *L.* **tengyuehensis** (p. 82); *L.* **phyllocephala** (p. 83); *L.* **fistulosa** (p. 84); *L. deltoidea* v. **brunelloides** (*L. b.* Pax et Hffm.) (p. 88); *L.* **gymnocephala** (p. 95); *L.* **patungensis** (p. 97); *L.* **crista-galli** Pamp. (p. 98); *L.* **robusta** (p. 116); *L.* **tsarongensis** (p. 117). The paper ends with 3 excluded species belonging to other genera.—*F. C. Gates.*

2076. HICKEL, R., et A. CAMUS. Fagacées. In: **H. LECOMTE et F. GAGNEPAIN.** *Flore Gén. Indo-Chine* 5(9): 937-1028. 7 pl. 1929.—Three genera are recognized: *Quercus* (38 spp.), *Pasania* (72 spp.) and *Castanopsis* (47 spp.). Keys to genera and species are given. The following appear: *Quercus* **camusae** Trelease (*Q. geminata* Hick. and Camus, not Small) (p. 957), *Q.* **dilacerata** (p. 960), *Q. lindleyana* v. **longipetiolata** (p. 972), *Pasania* **bassacensis*** (p. 984), *P.* **fordiana** (*Quercus f.* Hemsl.) (p. 1003), *P. fissa* v. **tunkinensis** (*Quercus tunkinensis* Drake) (p. 1005), *Castanopsis clarkei* v. **pseudindica** (*C. p.* Hick. and Camus) (p. 1019) and *C. ceratacantha* v. **semiserrata** (*C. s.* Hick. and Camus) (p. 1020).—*E. D. Merrill.*

2077. MATHIAS, MILDRED E. Studies in the Umbelliferae. II. *Ann. Missouri Bot. Gard.* 16(4): 393-398. 1 pl. 1929.—**NEOPARRYA** (p. 393) with *N.* **lithophila*** (p. 393), New Mexico; *Eryngium* **wolffii** (p. 395), Mexico; *Pimpinella saxifraga* ssp. *nigra* (Mill.) Gaud., introduced into Washington and new to N. Amer.—*M. E. Mathias.*

2078. MELCHIOR, H. Die Gentianen des Colle d'Olen

(Monte Rosa-Gebiet) [Italy]. *Rep. Spec. Nov. Reg. Veg.* 24(14/21): 309-316. 1 fig. 1928.—The topography and character of the underlying rocks are briefly described. The previously known species of the region are: *Gentiana tenella* Rottb., *G. bavarica* v. *subacaulis* Schleich., *G. brachyphylla* Vill., *G. verna* vars. *vulgaris* L. and *elongata* Haenke, and *G. ramosa* Hegtschw. Three additional species (*G. kochiana* Perr. & Song., *G. terglouensis* Hacq. var. *schleicheri* Vacc., known previously only from a few stations in the Wallis Alps, Switzerland, and *G. nivalis*) are reported, also the hybrid* *G. bavarica* var. *subacaulis* × *brachyphylla*, previously not described. Geographic distribution and synonymy and a bibliography are included.

2079. **MUNZ, PHILIP A., and C. LEO HITCHCOCK. A study of the genus Clarkia, with special reference to its relationship to Godetia.** *Bull. Torrey Bot. Club* 56 (4): 181-197. 1929.—*Godetia* is maintained as a genus distinct from, and more primitive than, *Clarkia*. A table shows the characters of *Godetia* and the 3 subgenera of *Clarkia: Phaeostoma* Spach (lowered from generic rank), *Euclarkia*, and the most highly developed member, *Eucharidium*. Seven species of *Clarkia* are keyed and described, synonymy discussed, and specimens cited. *Clarkia rhomboidea* f. **virgata** (*C. v.* Greene) is proposed. —*N. C. Fassett.*

2080. **[PITTIER, H.] Contribuciones para la flora de Venezuela. Geraniales.** *Trab. Mus. Comerc. Venezuela* No. 7. 293-356. 1930.—Keys are given to families, and to Venezuelan genera and spp. The systematic list includes references to original publication, citation of type localities, and other distributional records. Local names are given in some cases. Oxalidaceae: *Oxalis rhombifolia* v. **pubescens** (p. 310); *O.* **avilensis** (p. 310); *O.* **meridensis** (p. 311); *O.* **glandulosa** (*O. pubescens* var. *g.* Knuth) (p. 311); *O.* **jahnii** (p. 312); *O.* **nodulosa** (p. 313). All new forms are from Venezuela.

2081. **POELLNITZ, KARL von. Zur Kenntnis der Gattung Anacampseros L. III.** *Rep. Spec. Nov. Reg. Veg.* 28(751/755, paper 5): 27-32. 1930.—Material studied was primarily from the Albany Mus., Bolus Herb., and National Herb. of Pretoria. There is specimen citation for 15 known species. *A.* **bremekampii** (p. 29), Cape of Good Hope; *A.* **alta** (p. 30), and *A.* **herreana** (p. 30), Namaqualand; *A.* **avasmontana** (p. 31). A key to the 17 species of subgenus *Avonia* is provided.—*H. K. Svenson.*

2082. **RECHINGER, K. H. fil. Beiträge zur Kenntnis von Rumex Sekt. Lapathum.** *Rep. Spec. Nov. Reg. Veg.* 26(7/15): 177. 1929.—*R.* **aquitanicus** (p. 177), Pyrenees, France.

2083. **ST. JOHN, HAROLD. Calluna vulgaris, a recent adventive on Sable Island, Nova Scotia.** *Jour. Bot.* 67(11): 306-307. 1929.—*Calluna vulgaris,* mistakenly reported to have been collected on Sable Island in 1899, proves rather to be a recent introduction on the island.

2084. **SANDWITH, N. Y. Contributions to the flora of tropical America: I. New and less-known species of Schlegelia.** *Kew Bull. Misc. Inform.* 1930(5): 210-215. 1930.—*Schlegelia* **ramizii** (p. 211), which had been published without a description as *Citharexylum ramizii* Glaziou; *S.* **darienensis** (p. 212), Colombia; *S.* **scandens** (*Citharexylum s.* Briquet et Spruce) (p. 214). An emended description is given of *S. spruceana* K. Schum. —*N. Y. Sandwith.*

2085. **SCHWANTES, G. Zur Systematik der Mesembrianthemen.** *Zeitschr. Sukkulentenk.* 2(10): 173-176; (11): 177-189. 1926.—The author divides the genus *Mesembryanthemum* into the following new genera: **STOMATIUM,** with subg. **EU-STOMATIUM** (p. 175) and **CHASMATOPHYLLUM** (p. 176), and the following: *S.* **agninum** (*M. a.* Haw.), *S.* **mustellinum** (*M. m.* S. D.), *S.* **suaveolens** (*M. suaveolens* ms. Schwantes sp. nov.), *S.* **ermininum** (*M. e.* Haw.), *S.* **musculinum** (*M. m.* Haw.) (p. 176); **FAUCARIA** (p. 176), with *F.* **tigrina** (*M. tigrinum* Haw.), *F.* **tuberculosa** (*M. tuberculosum* Rolfe), *F.* **felina** (*M. felinum* Hill), *F.* **lupina** (*M. lupinum* Haw.), *F.* **bosscheana** (*M. bosscheanum* Berger) (all p. 177); **ALOINOPSIS** (p. 177), with *A.* **aloides** (*M. a.* Haw.), *A.* **vittata** (*M. vittatum* N. E. Br.), *A.* **cibdela** (*M. cibdelum* N. B. Br.), *A.* **albinota** (*M. albinotum* Haw.), *A.* **albipuncta** (*M. albipunctum* Haw.), *A.* **transvaalensis** (*M. transvaalense* Rolfe), *A.* **rubrolineata** (*M. rubrolineatum* N. E. Br.), *A.* **rosulata** (*M. rosulatum* Kensit) (all p. 178); **TITANOPSIS,** with *T.* **calcarea** (*M. calcareum* Marl.) and *T.* **schwantesii** (*M. s.* Dtr.), (p. 178); **DIPLOSOMA,** with *D.* **retroversum** (*M. r.* Kensit) (p. 179); **BERGERANTHUS** (p. 179), subg. **EU-BERGERANTHUS** (p. 180) with *B.* **scapigerus** (*M. scapigerum* Haw.), *B.* **multiceps** (*M. m.* Haw.), *B.* **vespertinus** (*M. vespertinum* Berger), *B.* **ignavus** (*M. ignavum* ms. n. sp.), *B.* **rehneltianus** (*M. rehneltianum* Berger), subgenus **HEREROA,** with *B.* **puttkamerianus** (*M. puttkamerianum* Dtr. et Brgr.), *B.* **derenbergianus** (*M. derenbergianum* Dtr.), *B.* **montis-moltkei** (*M. m.* Dtr.), *B.* **granulatus** (*M. granulatum* N. E. Br.), *B.* **carinans** (*M. c.* Haw.), subg. **RHOMBOPHYLLUM** with *B.* **rhomboideus** (*M. rhomboideum* S.-D.), subg. **CARRUANTHUS** with *B.* **caninus** (*M. caninum* Haw.), *B.* **cookii** (*M. c.* L. Bolus), *B.* **albidus** (*M. albidum* L.) (all p. 180); **MITROPHYLLUM** (p. 181), sug. **EU-MITROPHYLLUM** with *M.* **mitratum** (*Mesembrianthemum m.* Marloth), *M.* **proximum** (*Mes. p.* N. E. Br.), *M.* **dissitum** (*Mes. d.* N. E. Br.), *M.* **cognatum** (*Mes. c.* N. E. Br.), subg. **MONILARIA** with *M.* **moniliforme** (*Mes. m.* Thunb.), *M.* **pisiforme** (*Mes. p.* Haw.), *M.* **clivorum** (*Mes. c.* N. E. Ktze.), *E.* **mucronifera** (*M.* mucroniferum Haw.), *E.* **clausa** (*M. clausum* Dtr.), *E.* **sedoides** (*M. s.* Dtr. et Brgr.), (all p. 189).

2086. **SCHWANTES, G. Neue Mesembriaceen VI.** *Monatsschr. Deutschen Kakteen-Ges.* 2(3/4): 64-69. 2 fig. 1930.—*Ruschia* **meyerae*** (p. 64), *R.* **nobilis** (p. 65), *R.* **nelii** (p. 66) [no locality given], *R.* **robusta** (p. 66), *R.* **amoena*** (p. 66); all from Namaland except as stated. A classified list of subgenera (with their sections) of *Ruschia* is given.

2087. **SKOTTSBERG, C. On some arborescent species of Lobelia from tropical Asia.** *Acta Horti Gothoburgen-*

sis 4: 1-26. 4 pl., 7 fig. 1929.—Six species of *Lobelia*, *L.* **leschenaultiana*** (*Rapuntium leschenaultianum* Presl). (p. 4), *L. nicotianaefolia** Heyne, *L. n.* var. **macrostemon*** (p. 13), *L.* **philippinensis*** (p. 13), *L. trichandra** Wight, *L.* **doniana*** (p. 19), and *L. pyramidalis** Wallich, all of southeastern Asia except *L. philippinensis*, are described and their relationships discussed in detail. The Hawaiian Lobeliaceae are considered to show closer relationship to the southeastern Asiatic forms than to the American ones. A bibliography is given.—*Roxana S. Ferris.*

2088. [SOSNOVSKIĬ, D. I.] СОСНОВСКИЙ, Д. И. Критический обзор рода **Psephellus.** [Critical review of the genus Psephellus. (Abstract.)] Дневник Всесоюзного Съезда Ботаников, Ленинград, 1928 [*Proc. All-Russ. Congr. Botanists, Leningrad, 1928*] 1928: 128. 1928.—Report of study on the genus *Psephellus.*

2089. **STANDLEY, PAUL C. A new Brosimum from Panama, with notes on the generic names Brosimum and Ferola.** *Tropical Woods* 17: 8-11. 1929.—*Brosimum* **caloxylon** (p. 11). There are two distinct groups of *Brosimum* spp.: those with whitish or yellowish wood and those with red wood. Although the name *Ferolia* Aubl. was given to the genus 13 years ahead of *Brosimum* Swartz, both can be kept if the 2 groups prove to be distinct genera.—*W. N. Sparhawk.*

2090. **STEARN, W. T. Plants new or noteworthy. Vinca major var. oxyloba.** *Gard. Chron.* [*London*] 88 (2295): 516. 1930.—New variety from cultivation in England.

2091. **STEENIS, C. G. G. J. van. Malayan Bignoniaceae, their taxonomy, origin and geographical distribution.** *Rec. Trav. Bot. Néerl.* 24(4): 787-1049. 16 fig., 2 maps. 1927.—The taxonomical part of this paper opens with a key for the genera and the subgenera of this family, followed by a practical key for the genera of Malaya, the Philippines, New Guinea, Australia and New Caledonia, wild as well as cultivated. Emended Latin diagnoses are given of some genera and subgenera; the others are described in English. A key of the species is added to each genus, and all species have been described with indications on their geographical distribution. Latin diagnoses are given of the following species and varieties: *Nyctocalos brunfelsiaeflorus** Teysm. & Binnend., emended description; *N. cuspidatum* v. **oblongum** (p. 815), Philippines; *Arrabidaea* **magnifica** Sprague, mss. (p. 830), Colombia; *Pandorea* **baileyana*** (*Tecoma b.* Maiden & Baker), (p. 849); *P.* **poincillantha*** (*Bignonia p.* Zipp.), with var. **fragrans** (p. 858), New Guinea; *Tecomanthe* **amboinensis*** (*Tecoma a.* Blume), (p. 890); *T.* **ternatensis*** (p. 893), Ternate; *T.* **hillii*** (*Tecoma h.* F.v.M.), (p. 894); *T. venusta** ssp. **parviflora** (p. 897), New Guinea; *Deplanchea* **novocaledonica*** (p. 914), New Caledonia; *D. tetraphylla* var. **novoguineensis** (p. 917), New Guinea; *D.* **sessilifolia*** Viellard (p. 918), New Caledonia; *D.* **glabra*** (*Diplanthera g.* v. Sts.); *D.* **hirsuta*** (*Diplanthera h.* Bailey); *D.* **bancana*** (*Diplanthera b.* Scheffer), with var. **glabra*** (p. 923), Malay Peninsula and Sumatra; *D.* **tubulosa*** (p. 926), New Guinea; *Dolichandrone* subgen. **CORIACEAE** (p. 931) and **MEMBRANACEAE** (p. 936); *Stereospermum suaveolens* f. **verticillata** (p. 950), Java; *Radermachera* **sorsogonensis** Elmer mss. (p. 973), Philippines; *R. fenicis* var. **acuminata** (p. 980), Philippines and Celebes; *R.* **punctata** Elmer mss. (p. 982), Philippines; *R.* **fragrans** (*R. elmeri* var. *f.* Elmer) (p. 996); *Haplophragma* **macroloba** (*Spathodea m.* Miq.). The author emphasizes the fact that the Australian spp. of *Dolichandrone* (subg. *Coriaceae*) are separated from the other species (subg. *Membranaceae*). A scheme of the phylogenetic relations within the genus *Tecomanthe* H. Bn. is made, based upon the structure of the ovary, together with the habitus and the geographical distribution. There are striking indications that within *Tecomanthe* parallelly developed montane and alpine species can be distinguished. The affinities with the Neo-tropical Bignoniaceae make it probable that the Malayan Bignoniaceae have originated from Neo-tropical ones and have been part of a Tertiary flora. An hypothesis is made about the routes along which these tropical genera have migrated. The Bignoniaceae point to the same genetic-phytogeographical relations as do many other families. The author is opposed to Willis' age and area-theory, especially because one is generally unable to distinguish at first sight the difference between a progressive and a relic-endemic. The geographical distribution of the Malayan Bignoniaceae may be explained by Weber's line, though some of them existed in Malaya before this line represented a real barrier for biological distribution. On a number of maps is shown the geographical distribution of *Nyctocalos* T. et B., *Oroxylum indicum* (L.) Vent., *Pandorea* (Endl.) Spach, *Tecomanthe* H. Bn., *Neosepicea viticoides* Diels, *Hausmannia jucunda* F.v.M., *Deplanchea* Vieill., *Dolichandrone* (Fenzl) Seem., *Radermachera* Zoll., and *Haplophragma* P. Dop., and a scheme of phylogenetic relations of Bignoniaceae in recent and earlier times.—*M. J. Sirks.*

2092. **TISCHER, A. Corpuscularia perdiantha Tisch. spec. nov.** *Monatsschr. Deutschen Kakteen-Ges.* 2(1): 20-21. 1 fig. 1930.—*C.* **perdiantha*** (p. 20), Namaqualand.

2093. **TOLMATCHEW, A. Papaver nudicaule L. und einige verwandte asiatische Papaver-Formen.** *Svensk Bot. Tidskr.* 24(1): 33-43. 4 fig. 1930.—The author gives an emended description of *P. nudicaule* ssp. *commune** Turcz., which he regards as the type of *P. nudicaule* L.; *P. rubro-aurantiacum* ssp. **typicum*** (*P. nudicaule* ssp. *rubro-aurantiacum* var. *t.* Fedde) (p. 38), ssp. **setosum** (p. 39), Transbaikalia, while ssp. *langeanum* Lundström from Greenland is considered a distinct species; *P.* **tenellum*** (Korshinsky in sched.) A. Tolm. (p. 40), Siberia; *P. nivale,** redescribed.

Veg.* 26(1/6): 1-20. 2 pl. 1929.—The following spp. are added: *Heterotoma* **endlichii*** (p. 1) and *Lobelia* **schmitzii*** (p. 2), Mexico; *L.* **hosseusii*** (p. 2), Siam; *L.* **paradoxa*** (p. 2), Philippines; *L.* **thorelii*** (p. 3), Indo-China; *L.* **bollii*** (p. 3), Texas; *L. puberula* v. **mineolana** (p. 4), Texas; *Rhizocephalum* **gracile*** (p. 4), Peru; *Clermontia* **rockiana** (p. 4), Hawaii; *Centropogon* **longipetiolatus** (p. 5), Peru; *C.* **rimbachii*** (p. 5), Ecuador; *C.* **roraimanus*** (p. 6), Brazil; *C.* **scabellus*** (p. 6), Colombia; *C.* **psilandrus** (p. 7), and *C. subandinus* v. **ventricosus*** (p. 8), Ecuador; *C.* **tessmannii*** (p. 8), Peru; *C.* **rex*** (p. 8), *C.* **cinnabarinus*** (p. 9), *C.* **ozotrichus*** (p. 10) and *C.* **polytrichus** (p. 11), Colombia; *C.* **weddellii*** (p. 11) and *Siphocampylus* **nobilis*** (p. 12), Peru; *S.* **bogotensis** (p. 12), Colombia; *S.* **puberulus*** (p. 13), Bolivia; *S.* **ravidus*** (p. 13), *S.* **schultzeanus*** (p. 14), *S.* **hypsophilus*** (p. 14), *S.* **megalanthus** v. **orthosepalus** (p. 15), and *S.* **lecomtei** (p. 15), Colombia; *S. imbricatus* v. **casarettoi** (p. 16), Brazil; *S.* **krauseanus*** (p. 16) and *S.* **albus*** (p. 17), Peru; *S.* **trianae*** (p. 17), Colombia; *S. retrorsus* (Willd.) Vatke, redescribed, with vars. **asper** (*S. a.* Benth.), (p. 18), **semiasper** (p. 19), Colombia, and **eximius** (*S. e.* Planch), (p. 19).

FLORISTICS AND PLANT DISTRIBUTION

2095. **ARWIDSSON, TH. Floran inom Sonfjällets national park.** *K. Svenska Vetenskapsakad. Skrifter i Naturskyddsärenden* No. 12. 1-37. 1 map. 1930.—This Swedish national park is situated in the province Härjedalenl. It has an area of 27 myriare, an altitudinal variation of about 900 meters. The flora of vascular plants comprises (including 22 Pteridophyta and 3 Gymnospermae), 250 spp. in 51 families.—*T. Arwidsson.*

2096. **BIASIONI, L. Nuove osservazioni sulle piante avventizie di Trento e dintorni. [Observations on the adventitious plants of Trento, Italy, and vicinity.]** *Studi Trentini Sci. Nat.* 10(3): 218-226. 1929.—An annotated list of about 137 forms, with habitat records. Rubiaceae: *Asperula arvensis* f. **simplex** (p. 221). Compositae: *Anthemis arvensis* v. **subunicephala** (p. 221). Labiatae: *Galeopsis ladanum* v. **brevipila** (p. 224). Euphorbiaceae: *Mercurialis annua* f. **pygmaea** (p. 225).

2097. **CLELAND, J. B., and J. M. BLACK. Plants of the Encounter Bay district.** *S. Australian Nat.* 10(3): 37-40. 1929.—An annotated supplementary list compris-

ing Filicales (1), Lycopodiaceae (1), and many spermatophytes of various families.

2098. CLELAND, J. BURTON. Notes on the botany of central Australia. Parts 1 & II. *S. Australian Nat.* 11(1): 1-4. 1 pl. 1929; (2): 21-23. 1 pl. 1930.—This is a report on an expedition to the McDonnell Ranges and vicinity in August, 1929. Three botanical areas are treated: the plains and broad valley; the foothills, mountains, and gorges; the watercourses and their pools. There are notes on numerous species met with in each area.

2099. CRATTY, R. I. Iowa plant notes, II. *Proc. Iowa Acad. Sci.* 33: 125-128. 1926[1927].—Reports 47 species of angiosperms and pteridophytes as new to or rare in Iowa—*H. S. Conard.*

2100. CZERNIAKOWSKA-REINECKE, E. Letzte Neuheiten über die Flora Turkmenistans und Nordpersiens. *Rep. Spec. Nov. Reg. Veg.* 27(741/750; paper 28): 262-287. 1930.—A summary of the latest discoveries in the mountainous region of northern Persia, chiefly in the Kopet-dagh and Chorassan Mts. Notes are given on collections other than that of the author, especially the large one of E. Tscherniakowska now at Leningrad. There are extensive notes on 73 spp. (19 new to the region) in 56 genera, together with an itinerary from 1916 to 1927, and bibliography of the author's work on the region. *Merendera* **jolantae** (p. 264), North Turcoman; *Gagea capillifolia* Vved. (in "Flora von Turkmenistan"); *Corydalis* **chionophila** (p. 268), *Moriera* **gracilis** (p. 269), *M.* **transhyrcana** (p. 270), *Stellera* **turcomanica** (p. 273), and *Acantholimon* **blandum** (p. 275), Turcoman; *A.* **raddeanum** (p. 276), Persia; *Paracaryum* **gracile** (p. 277), *Lagochilus* **balchanicus** (p. 278), *Salvia* **semilanata** (p. 278), and *Veronica* **khorassanica** (p. 280), Turcoman; *Pterocephalus* **khorassanicus** (p. 281), Persia; *Centaurea* **iljini** (p. 285), Turcoman; *Taraxacum serotinum* v. **chorassanum** Dahlstedt (p. 286), Persia.—*H. K. Svenson.*

2101. DIELS, LUDWIG, und G. SAMUELSSON. Larix Miller. *Die Pflanzenareale* 2(7): 59-75. 9 maps. G. Fischer: Jena, 1930.—Distribution of the following is discussed, and indicated on maps: the species of *Larix* (by C. H. OSTENFELD and C. SYRACH-LARSEN), maps 62-64; of *Hedera* (by L. LÄMMERMAYR), maps 65-68; of *Cornus* § *Arctocrania* (by C. REGEL), map 69; and of the European Gesneraceae (by A HAYEK), map 70.

2102. DRUCE, G. CLARIDGE. The flora of West Ross [Scotland]. With introductory sketches of the topography and climate and also biographical notices of those who have contributed to the flora since 1778. *Bot. Soc. & Exchange Club British Isles* [*Supplement*] 8(5): v-112. 1 pl. 1929.—The plants reported are classified as to habitat. The annotated list comprises 809 spp.

2103. GARDNER, CHARLES A. Enumeratio plantarum Australiae occidentalis. A systematic census of the plants occurring in Western Australia. *Jour. Dept. Agric. W. Australia* 7(1): p. i-v+1-34. 1930.—This 1st installment lists the plants by scientific names from Pteridophyta, to Dicotyledoneae Proteaceae; 3 other parts are to follow. Each specific name is followed by the authority with reference. Synonyms are included.

2104. GRÖNTVED, JOHS. Die Flora der Insel Runö. *Svensk Bot. Tidskr.* 23(4): 399-460. 2 maps. 8 fig. 1929. —This Esthonian island, comprising 11 square kilometers in the midst of the Riga Gulf, has an insular climate although influenced by the near Russian continent. The eastern half has a fine pine wood (*Pinus silvestris*) on old dunes, the western half being low, partly cultivated, partly hay-meadows and grazing-grounds. A complete list of species is given with notes concerning localities, occurrence, etc.; there are 470 spp. of phanerogams and 9 of vascular cryptogams. Some interesting species, e.g., *Ophioglossum vulgatum, Calla palustris, Sorbus suecica* and *Crambe maritima* are discussed.—*J. Gröntved.*

2105. HANDEL-MAZZETTI, HEINRICH. Bearbeitung der von E. Zugmayer in Tibet gesammelten Phanerogamen. *Österreich. Bot. Zeitschr.* 79(1): 30-39. 1930.—An annotated list of Spermatophyta, including *Aster* **glandulosus** (*A. flaccidus* var. *g.* Keissl.) (p. 35).

2106. JOHNSTON, IVAN M. I. Papers on the flora of northern Chile: 1. The coastal flora of the departments of Chañaral and Taltal; 2. The flora of the nitrate coast; 3. Undescribed species from the Cordilleras of Atacama. II. Some undescribed species from Peru. *Contrib. Gray Herb. Harvard Univ.* No. 85. 1-180. 2 pl. (1 map.) 1929.—(I.I.) The coasts of Chañaral and Taltal are characterized by the large number of endemic spp. and the sharp contrast of mesophytic and xerophytic associations. The rainfall averages 11 mm. per year, but in the belt of altitude between 300 and 800 m. on the slopes facing the ocean, and in the valleys extending inland from the ocean, the low rainfall is compensated by a moist ocean fog which gives these areas high humidity and a moist soil. The fog belt has a luxuriant spring vegetation, of which *Cereus spinibarbis, C. coquimbanus,* and *Euphorbia lactiflua,* xerophytes able to persist through the fogless summer, are characteristic. In the moist season these plants are frequently covered with fruticose and foliose lichens, and may support the epiphyte, *Tillandsia geissei.* Below the fog belt there is a xerophytic flora, with narrow and usually thickened foliage. Above the fog belt there is usually an arid scrub composed largely of *Echinocactus,* then a zone of hardy deep-rooted xerophytes extending to about 1000 m. altitude, above which no plants survive. The area is a southern extension of the Loma zone, which is well developed in Peru. Most of the plants are southern in affinity, although some are closely related to Mediterranean or to Californian species. Of the 394 spp. and varieties, 145 are endemic, 4 endemic genera (*Werdermannia,* Cruciferae; *Domeykoa,* Umbelliferae; *Gypothamnium* and *Oxyphyllum,* Compositae) are recorded. Based on the author's collections and on those of Philippi and others, an annotated and descriptive list of the spp. and varieties is given. Polypodiaceae: *Asplenium fragile* v. **lomense*** Weatherby (p. 13); *Polypodium* (Sect. *Goniophlebium*) **espinosae*** Weatherby (p. 15), with a key to distinguish it from related species. Dioscoreaceae: *Dioscorea* **cylindrostachya** (p. 25). Iridaceae: *Tigridia* **philippiana** (p. 26). Orchidaceae: *Bipinnula* **taltalensis** (p. 27); *B.* **fimbriata** (*Chloraea f.* Poepp). Chenopodiaceae: *Atriplex* **taltalensis** (p. 30); *A.* **clivicola** (p. 31) with var. **lopholepis** (p. 31). Amarantaceae: *Alternanthera* **junciflora** (*Telanthera j.* Remy) (p. 32). Aizoaceae: *Tetragonia* **tenella** (p. 34). Portulacaceae: *Calandrinia* **sitiens** (p. 35); *C.* **cephalophora** (p. 35); *C.* **taltalensis** (p. 37); *C.* **lamprosperma** (p. 37); *Portulaca* **philippii** (p. 39). Caryophyllaceae: *Spergularia* **arbuscula** (*Paronychia a.* Gray) (p. 40); *S.* **stenocarpa** (*Arenaria s.* Ph.) (p. 41); *S.* **cremnophila** (p. 41). Cruciferae: *Menonvillea parviflora* v. **aptera** (*M. a.* Ph.) (p. 44); *Werdermannia* **anethifolia** (*Nasturtium anethifolium* Ph.) (p. 45). Leguminosae: *Astragalus* **vasticola** (*Phaca atacamensis* Ph.) Solanaceae: *Schizanthus* fallax (p. 160); *Salpiglossis* brachysiphon (p. 161).—(I, 3.) The following are undescribed species from the Cordilleras of Atacama: *Ephedra* (§ *Pseudobaccatae*) wraithiana (p. 164); *Cardamine* (?) cremnophila (p. 165); *Hexaptera* macrocarpa (p. 166); *Astragalus* valerianensis (p. 166); *Cristaria* glomerulata (p. 167); *Euphrasia* adenonota (p. 168) (Trifidae); *Senecio* pelolepis (p. 169); *S.* tinctolobus (p. 170); *Polyachyrus* rigidus (p. 171); *Pachylaena* rosea (p. 171).—(II.) The following are from Peru: *Linum* parvum (p. 172); *Eremocharis* confinis (p. 173); *E.* triradiata (*Asteriscium t.* Wolff) (p. 174); *E.* dissecta (p. 174); *E.* longiramea (*Asteriscium longirameum* Wolff) (p. 174); *Nolana* plicata (p. 174); *Bargemontia* platyphylla (p. 175); *B.* gracillima (p. 176); *B.* confinis (p. 176); *Cacabus* flavus (p. 177); *Salpiglossis* albiflora (p. 178); *S.* acutiloba (*S. linearis* Johnston not Hook.) (p. 179); *Polyachyrus* mollendoensis (p. 179).

2107. KARPOWICZ, KAROL. Przyczynek do znajomości flory powiatu Nowogródzkiego. [Flora of the district of Nowogródek, Poland.] *Planta Polonica* (*Contrib. Flore Pologne*) 1: 1-102. Map, 4 pl. 1930.—Following an historical résumé of studies of the region, description of topography, etc., the author presents 3 lists: (1) 804 spp. of angiosperms, gymnosperms, and pteridophytes in the district and in the neighboring communes of Minsk, Wilno, and Grodno; (2) a list of 63 angiosperms cultivated in the district; (3) a list of 93 decorative angiosperms and gymnosperms of the district.

2108. LIU, J. C. A list of plant names included in the Cowdry Chihli Flora not recorded in the Index Florae Sinensis and its two supplements. *Jour. North China Branch Roy. Asiatic Soc.* 60: 120-126. 1929.—An alphabetic list of angiosperms from Chihli, China.

2109. LIU, J. C. Important bibliography on the taxonomy of Chinese plants. *Peking Soc. Nat. Hist. Bull.* 4(3): 17-32. 1930.—The principal papers containing descriptions of Chinese plants are cited alphabetically: by author, if books; by title, if periodicals.

2110. MAHONY, KENNETH L. Preliminary reports on the flora of Wisconsin. III. Lobeliaceae, Campanulaceae, Cucurbitaceae. *Trans. Wisconsin Acad. Sci. Arts & Lett.* 24: 357-361. 14 maps. 1929.—Statements of distribution, with a map for each species.

2111. PALMER, ERNEST J. The spontaneous flora of the Arnold Arboretum [Massachusetts]. *Jour. Arnold Arboretum* 11(2): 63-119. 1 pl. 1930.—A systematic list of the Pteridophyta and Spermatophyta observed in the grounds of the Arnold Arboretum preceded by a general description of the Arboretum and of its geological features and an account of the distribution of the spontaneous vegetation of the cultivated area and of the various spots which have remained more or less in their natural condition. The plate represents an aeroplane view of the Arboretum. —*A. Rehder.*

2112. PAMPANINI, RENATO. La flora del Caracorùm. [The Karakoram Range, Kashmir.] *Sped. Italiana de Filippi, Ser.* 2. 10: 3-285. 23 maps, 6 pl., 3 fig. 1930.—A detailed account is given of prior botanical exploration and collection. Maps and discussion give the itinerary of each collector, and lists of the plants added by each to the flora are given. G. Dainelli and O. Marinelli, botanists of the Filippi expedition (1914), collected 165 specimens (fungi (4), Gnetaceae (1)) falling in 92 species (here enumerated). Diagnosis of the 13 spp. and varieties which proved to be new, are re-printed. A detailed journal of collections, showing the site of collections, the altitude and the spp. found at each site, is given. Altitudes varied from 4750 to 5420 meters. The plants found are listed according to the altitude at which collected. A comprehensive annotated list of the plants known from the region (including those reported by earlier collectors as well as those found by Dainelli & Marinelli) is given, and includes: Eumycetes (5), Lichenes (2), Musci (3), Pteridophyta (5), Equisetaceae (2), Gymnospermae (9), Angiospermae (756). A table shows the number of genera, spp., subspp., varieties and forms in each family. The distribution of the spp. in the region is treated in great detail. Tables show the distribution of the 109 Tibetan and 87 Pamiric spp. in the region. The altitudinal relationship of the spp. in eastern and western Karakoram is treated. The range of altitude occupied by the various spp. is indicated in a table. The 39 Arctic spp., the 37 southern spp., the 112 Eurasian, the 16 Occidental, the 11 Oriental, the 58 Mediterranean, the 95 Central Asian, comprising the Karakoram flora, are tabulated as to distribution within the region. Endemism is rare in the region. The plants are again listed, the upper altitudinal limit of each being given. The bibliography lists 121 papers on the botany of Karakoram. New for Karakoram were: *Astragalus arnoldii** Hemsl. et Pears, *Atropis distans* v. *convoluta* f. *glaberrima* (Hack.) Pamp., *Braya tibetica* Hook. f. et Thoms., *Crepis gracilipes* Hook. f., *Danthonia cachemiriana* Jaub. et Spach., *Festuca valesiaca* Schleich., *Pleurogyne thomsonii* C. B. Clarke, *Poa pratensis* v. *alpigena* Blytt, *Ranunculus similis* Hemsl., *Saussurea aster** Hemsl., *S. thoroldii** Hemsl., *Astragalus zacharensis, Gagea perspica* and *Oxytropis malloryana.* The following combinations are given: *Atropis distans* v. *convoluta* f. glaberrima (*A. convoluta* var. *g.* Hackel ap. Keissler (p. 77); *A.* thomsonii (*Glyceria t.* Stapf, ap. Hooker) (p. 77); *Polygonum alatum* v. *nepalense* f. scabridum (*P. n.* var. *s.* Meissn.) (p. 98), *Clematis orientalis* v. tenuifolia (*C. t.* Royle) (p. 110); *Draba cachemirica* v. pulvinaris (*D. alpina* var. *p.* Henrard) (p. 123); *Waldheimia* vestita (*Allardia v.* Hook. f. et Thoms.) (p. 208); *Ligularia arnicoides* v. frigida (*Senecio a.* var. frigidus (Schultz-Bip.) (Hook. f.) (p. 215); *Cirsium arvense* v. negletum (*Cnicus arvensis* v. *neglecta* (Fisch.) Klatt) (p. 221); *Chrysanthemum* pamiricum (*Pyrethrum p.* O. Fedtsch.) (p. 205).

2113. PRAEGER, R. LLOYD. Phanerogamia and Cryptogamia vascularia. Supplement to "Irish Topographical Botany," 1906-1928. *Proc. Roy. Irish Acad.* 39B(1): 57-78. 1929.—Using the standard for species and

subspecies adopted in "Irish Topographical Botany," and extending it to recent additions to the flora, we find the number of new plants (native or naturalized) added to the flora of Ireland in 1913-28 to be 30. This excludes a number of segregates in such genera as *Rosa, Leontodon, Thymus,* etc. Among these 30 species are *Mentha requienii* Benth. and *Spiranthes stricta** Nelson (colored plate), previously considered as *S. romanzoffiana,* which now disappears from the Irish flora. *Arctostaphylos alpina, Erica stricta,* and *Selaginella kraussiana* are doubtful members. The report contains extensions of range, refindings and confirmation of 8 species, addition of 6 hybrids, withdrawal of 7 species, and new records arranged under county divisions, with references to publications.

2114. **SKOTTSBERG, C. Notes on some recent collections made in the Islands of Juan Fernandez.** *Acta Horti Gothoburgensis* 4: 155-171. 2 pl., 3 fig. 1929.—The four collections made by Bürger, Tenz, Bock and Looser, respectively, reported upon, supplement an earlier paper by the author on the flora of Juan Fernandez. Among the ferns and angiosperms noted is **YUNQUEA** (Compositae) (p. 163), type *Y.* **tenzii*** (p. 163), related to *Centaurodendron,* another endemic. These, with all the native flora, are in danger of extermination before sufficient data concerning them have been gathered.—*Roxana S. Ferris.*

2115. **STANDLEY, PAUL C. A second supplement of the flora of the Barro Colorado Island, Panama.** *Jour. Arnold Arboretum* 11(2): 119-129. 1930.—An enumeration of 63 species recently observed, including: *Odontocarya* **truncata** (p. 121), *Protium* **salvozae** (p. 122), *Saurauia* **zetekiana** (p. 124), *Eugenia* **banghamii** (p. 125), *E.* **melanosticta** (p. 126), *Markea* **panamensis** (p. 127), and *Petastoma* **breviflorum** (p. 128).—*A. Rehder.*

2116. **ANONYMOUS. Report on a second tour of the Botanical Section in the Province of Surat [Siam].** *The Record (The Jour. of the Bd. Commercial Development) [Bangkok]* 32: 316-321. 1 pl. 1929.—Itinerary, with notes on the flora.

MORPHOLOGY AND ANATOMY OF VASCULAR PLANTS

ARTHUR J. EAMES, *Editor*

(See also in B. A. 5(8/9): 19262, 19296, 19356, 19360, 19364, 21075, 21097, 21176, 21232, 21347; 5(10): 22696, 22702, 22709, 22830, 22883, 22900, 24296, 24304, 24547, 24566, 24792, 24884, 24919, 24973, 25041, 25196, 25274, 25332, 25361, 25369, 25375; 5(11): 26566, 26647, 26664, 26676, 26682, 26684, 26685, 26687, 26692, 26792, 26803, 26868, 26934, 26935, 27007, 27008, 27141, 27166, 27167, 27450, 29011, 29025, 29064, 29092; and in this issue 920, 2162)

2117. **ALMEIDA, J. F. R. d'. On the shoot morphology of Limnanthemum.** *Jour. Indian Bot. Soc.* 7(1): 1-11. 6 fig. 1928.—There are 2 Indian spp. *L. cristatum* Griseb. has a short rhizome, bearing leaves without branches in their axils, and with blades floating on the surface of the water. There is a gradual transition from these complete leaves to membranous scales, which bear long branches (stolons) in their axils. At the end of the stolon is a terminal inflorescence (corymb with a very short axis) and a floating leaf with a short petiole. In the axil of this leaf an "abbreviated stem" develops, bearing scale leaves with new stolons in their axils, and a few adventitious roots. *L. indicum* Thwaites is believed to bear long-petioled leaves while young, and the abbreviated stems formed at the end of the stolons bear one or more small floating leaves. Pieces of *L. cristatum* leaves can produce new plants. Repeated branching of *Limnanthemum* by means of stolons is an effective means of vegetative reproduction, of covering the water with leaf mosaics, and of checking the growth of competitors. The *Limnanthemum* habit is regarded as intermediate between the *Nymphaea* type, which is rooted in the mud, and the floating type, which has roots hanging freely in the water.—*W. Dudgeon.*

2118. **AVERY, GEORGE S. Jr. Comparative anatomy and morphology of embryos and seedlings of maize, oats, and wheat.** *Bot. Gaz.* 89(1): 1-39. 68 fig. 1930.—The scutellum in maize, oats, and wheat is the cotyledon. The "ventral scale" of the cotyledon, when present, may be interpreted as its ligule. The epiblast, when present, cannot be considered a rudimentary cotyledon; it probably has little morphological significance. These interpretations hold also for other grasses examined, including barley, rye, and rice. The coleoptile is homologous with a foliage leaf, and is the 2nd leaf of the plant, the leaf distal to it being the 3rd leaf of the plant. In maize and oat seedlings, the elongated structure between the cotyledon and the coleoptile is the first internode of the axis. The term "mesocotyl" as applied to this structure is meaningless, it being in no sense the middle portion of the cotyledon. In wheat, the corresponding structure, although not elongated, is likewise the 1st internode of the axis. This holds true for other Gramineae that develop similarly to maize, such as oats and rice, and those that develop like wheat, such as barley and rye. The principal elongating structure in the young wheat axis is the 2nd internode. It is always sheathed by the coleoptile. There is no hypocotyledonary region of "transition" in the grasses. The transition is confined to stem structure. It starts and takes place largely in the vascular plate at the 1st node, and in the 1st internode. The transition continues in the 2nd internode and to some degree even in the 3rd and 4th internodes. The 3 morphological types of grass seedlings distinguished by Van Tieghem are fundamentally 1 type, appearing differently upon development because of the difference in location of the meristematic region in the 1st internode. These differences often show in the mature embryo, before germination begins. The similarity of vascular skeletons of so-called seedling types is pointed out.—*G. S. Avery, Jr.*

2119. **ARBER, AGNES. Studies in the Gramineae. IX. 1. The nodal plexus. 2. Amphivasal bundles.** *Ann. Bot. [London]* 44(175): 593-620. 13 fig. 1930.—The 1st part of this paper relates to the origin and history of the plexus of more or less horizontal bundles which characterizes the nodes of Grasses, and to the vascular relations of the adventitious roots and lateral buds occurring at the nodes. Neither the bud-strands nor the root-strands can be held to be responsible for the inception of the nodal plexus. Nor can Bugnon's statement that the horizontal bundles in the node are formed by an abrupt change of direction of the longitudinal leaf-traces be accepted as a generalization, though it is no doubt true in individual cases. It is concluded that the formation of the horizontal strands is due to a recrudescence of meristematic activity, affecting the ground-tissue between the bundles. The origin of the plexus may thus be such that it is open to description as cauline. But this activity of the ground tissue may coincide with activity affecting the flanks of the intrafascicular cambium region in the vertical bundles, by means of which connections are established between the new horizontal strands and the pre-existing vertical leaf-traces. This cell-division in connection with the leaf-traces may be so closely contemporaneous with the initiation of the horizontal strands that the plexus may be described as originating through branching of the leaf-traces. Incidentally, the irregular relation of the vascular supply of the bud to that of the parent axis is discussed.—In the 2nd part of the paper the amphivasal bundles of Grasses are considered in comparison with those of *Acorus,* and the conclusion is reached that they represent, as a rule, a special modification of single collateral bundles, and that the statements which have been made as to their

general origin by bundle fusions are not warranted.—*A. Arber.*

2120. BRANDT, W. Über Entstehung und Funktion der Öldrüsen bei Labiaten und Compositen. *Proc. Internat. Congress Plant Sci., Ithaca, N. Y.*, 1926 2: 1362-1368. 12 fig. 1929.—In the Compositae the gland arises by the growth of a protoderm cell beyond the adjoining cells, a longitudinal division, and the transverse division, several times, of the 2 daughter cells. The young gland at this time presents an erect flattened somewhat heart-shaped structure, consisting of 6-8 cells covered with cuticle. The cells are rich in protoplasmic content, have well formed nuclei, and distinct walls. Before the formation of oil, the cell walls become indistinct and the nuclei disorganize. With the disappearance of the cell walls, the protoplasts may form one uniform mass, or remain separate. Only after the beginning of this disorganization does oil-formation start, and the more oil is produced, the greater the disorganization. The disorganization of cells begins mostly in the upper pair, and only occasionally in the lower groups. Cutinized membranes are permeable to water, but not to oil. Cutinization, therefore, permits the entrance of elaiogenous substances into the gland, but prevents the return of the oil into the tissue of the leaf. In the Labiatae, the glands develop by the projection of a protoderm cell and its division twice transversely. The outermost cell of this 3-celled trichome swells and becomes spherical or ellipsoidal. It may remain undivided, but usually it divides into 4, 8, or 12 cells by anticlinal divisions. The little head thus formed is rich in protoplasm and its cells have well defined walls and nuclei. The cuticle which covers it enlarges, forming a fold that runs completely around the head. As soon as this fold is completed, the cells composing the head disorganize, cell walls and nuclei disappearing. Oil formation begins with cell disorganization. The fold stretches out, and the oil reservoir thus formed is much larger than the cellular head. The cutinized lamella behaves here as in the oil glands of the Compositae, and oil is prevented from flowing back into the tissues. The author finds that the oil glands have nothing to do with the function of the leaf, and concludes that the oil is an excretion.—*C. C. Plitt.*

2121. CAPARARO, ELENA. Brevi note sopra gli idioblasti oleiferi nel frutto di Melia azedarach L. [Oil bearing idioblasts in the fruit of the China tree, M. azedarach.] *Natura [Milano]* 19(4): 167-171. 1928.—In the ovary numerous yellowish masses of idioblasts are seen in the carpel mesophyll. These idioblasts present in the ovary of the unopened and opened flower become progressively elongated while maintaining their characteristic yellowish color. In the mature fruit they are long, thin and pointed, sometimes irregularly bifurcated. The cell membrane is very thin. The average number of these cells in the just opened flower is 18; just after fall of the petals, 52; 10 days later, 65, which latter number is maintained. The idioblasts are believed to arise from the relatively undifferentiated mesophyll cells. They are detectable in the earliest stages of ovarian development (before ovules are formed) by their large size. In the adult state these cells contain fats, oils, and resins. Stained with Sudan III, they are colored orange red and the outlines of probable oil-producing centers are revealed. The pulp of the fresh fruit boiled first with water and then treated with tincture of henna shows numerous dispersed oily drops having a distinct vinous color. Aqueous solution of iodine does not color them but an alcoholic solution gives them an iodine tint. The mature fruit yields a fatty oil used in soaps, paints and medicines.—*J. G. Edwards (from abst. by E. Capararo).*

2122. CASELLA, DOMENICO. I cerchi legnosi nel genere Salix. [Growth rings in Salix.] *Ann. Tecnica Agraria* 1/2(5): 513-515. 2 pl. 1929.—Observations on stems of *Salix alba, S. purpurea, S. babylonica, S. nigricans* and *S. fragilis* from various regions of southern Italy show distinct and well marked annual rings, with the elements composing them uniformly distributed in all species.—*H. D. Hill.*

2123. DAMIANI, AIMÉE. Recherches anatomiques sur les feuilles de Vonitra et le Piassava de Madagascar. *Ann. Mus. Colonial Marseille* 7(2): (1-28.) 7 fig. 1929.—Differences in structure are less marked in terminal than in basal regions. The 4 known spp. of *Vonitra* may be distinguished by the anatomical structure of their leaves. *V. thouarsiana* shows meristeles regularly oval in cross section, the sheath enclosing 5 fibrovascular strands; an absence of subepidermal sclerenchyma; polyhedral and slightly elongated parenchyma cells; a small cavity in the fibers of the sheath; meristele wider than long; meristele of the ligule with only 1 fibrovascular strand. *V. utilis* shows meristeles more regularly and closely oval at the tip and less rounded at the base, the sheath enclosing 3 fibrovascular strands (in seedlings, the meristeles of the larger veins are in contact with upper epidermis, this reversed in older plants); an absence of subepidermal sclerenchyma; polyhedral and nearly isodiametric parenchyma cells; a large cavity in the fibers of the sheath; meristele longer than wide; meristele of the ligule with at least 3 fibrovascular strands. *V. crinita* shows meristeles rather pear-shaped with larger edge against lower epidermis, the sheath enclosing 10 fibrovascular strands; lower part of meristele with group of strands exclusively woody. *V. louvoubensis* shows meristeles very long with the 2 lateral edges nearly parallel, a convex tip and angular base, the sheath enclosing at least 20 fibrovascular strands; lower part of meristele as in *V. crinita* but separated at tip of meristele by several small fibrovascular strands (in seedlings the meristeles of the larger veins are in contact with upper epidermis, this is reversed in older plants). Differences between *V. thouarsiana* and *V. utilis* are of interest because similar characteristics mark the fibers of the piassava of commerce.—*H. D. Hill.*

2124. FRANCINI, E. Fenomeni di aposporia somatica, di aposporia goniale e di embrionia avventizia in "Ochna multiflora." Nota preliminare. [Somatic apospory, gonial apospory and adventitious embryony in O. multiflora. Preliminary note.] *Atti R. Accad. Naz. Lincei Rend. Cl. Sci. Fis. Mat. e Nat.* 7(1): 92-95. 1928.—*O. multiflora* may show somatic apospory and is thus the 3rd authentic example of this phenomenon. Gonial apospory, of the type of *Antennaria alpina,* may also occur and is more frequent than somatic apospory. The history of cells differentiated from the archesporium shows conditions intermediate between those in *Hieracium aurantiacum* and those in *Artemisia nitida.* The ♀ gametophyte remains in uninucleate stage a long time, finally attaining the 8-nucleate stage. There appears to be a tendency toward polyembryony.—*H. D. Hill.*

2125. GEORGESCU, CONST. Blattstellungsstudien an Echinocactus gibbosus. *Biologia Generalis* 3(1/2): 95-104. 1 pl. 1927.—An attempt to explain the question of leaf arrangement in the Cacti. The species here studied is especially suitable because at the apex of the stem the young leaf rudiments are readily observed. The superimposed bunches of leaves grow in straight rows along the ridges of the stem. A linear series shows that the phyllotaxy varies widely. The leaves are arranged symmetrically around the straight axis, or form longer or shorter spirals, or are arranged irregularly. An analysis of individual cases demonstrates that the deviation from the normal type of the dicotyledons is due to an intercalation of new and active sectors at the growing apex. This can be seen externally. Such phenomena have been known only in teratological cases. Their relationship to external factors, especially light, is assumed, but the necessary experimental evidence is lacking.—*M. Steiner (transl. by W. Steckbeck).*

2126. GRAFE, V. Die Textilien. Chemische Technologie der Zellulose. 2 Halbband des II Bandes von Handbuch der organischen Warenkunde. 770p. 597 fig. C. E. Pöschel: Stuttgart, 1928. Pr. 47.50 M.—This volume brings together comprehensive information on materials, their source, testing, technical handling, and production, and citations of literature on these sub-

jects. It includes the following: (1) O. RICHTER. **Anatomie und Mikrochemie der Textil- und Papierfasern aus dem Pflanzenreiche.** pp. 1-136. Characters valuable in the identification of hairs from seeds and from ferns (*Gossypium, Eriodendron, Asclepias, Calotropis, Osmunda, Abotium*); of bast and wood fibers (or similar elements); and of artificial silk fibers are discussed and figured. Microscopical structure and microchemical peculiarities useful in determining ancient and modern papers (or record-keeping materials) are also described and figured.—(2) G. von LINNERT, Die pflanzlichen und tierischen Textilien. pp. 137-388. After a brief historical résumé of the earliest use of textiles by man there is given a comprehensive survey of materials used today and their composition. Their general handling and treatment in spinning and weaving is discussed and illustrated in detail. The materials treated are not only fibers from seeds, stems, leaves, and fruits, but also animal wool, hair, tendons (for cordage), and silks, as well as mineral fibers and manufactured fibers such as artificial silks, showing their distinctive cross sections (magnified), and paper yarn.—(3) BRUNO POSSANNER von EHRENTHAL. Das Papier. pp. 389-492. The important characteristics of materials used in paper making,—wood fibers (representing $\frac{3}{4}$ of the total), cereal straw, grasses, and rags,—are discussed. The technical processes of preparing and processing the materials in making different kinds of paper, sizing, coloring, and testing them for purposes of identification or for evaluation of properties are described in considerable detail. Statistics of relative production are given.—(4) A. von FIETZ. Die Hölzer und ihre Bearbeitung. pp. 493-612. Following a discussion of the cellular structure of woody tissues, there are presented the importance of wood as a material, methods of harvesting, sawing and finishing, and data on its consumption. The characteristics of sapwood and heartwood, including chemical composition, color, luster, odor, taste, cleavability, weight, hardness, density, flexibility, and elasticity, are discussed. The treatment of wood to prevent deterioration, its relative natural durability against fungi and insects, and the anatomy of woody tissues, including their microscopical investigation, are also discussed for specific elements in monocots, conifers, and hardwoods. A description of the properties and structure of over 60 commercial woods, illustrated by numerous photomicrographs, is included.—(5) J. von NUSSBAUM. Chemische Verarbeitung der Zellulose. pp. 617-689. Cellulose produced by the soda, sulphate, and sulphite processes and the views concerning physical and chemical characteristics of cellulose, cellulose hydrate, hydrocellulose, oxycellulose, cellulose esters including nitrocellulose, its derivatives and their study, as well as those of cellulose acetate and cellulose ether, are discussed.—(6) V. von GRAFE. Pflanzengummi, Pflanzenschleime, Hemizellulosen. pp. 691-731. The occurrence and characteristics of a considerable number of these compounds together with their commercial significance are discussed. An author-subject index is appended.—*E. Gerry.*

2127. GORCZYŃSKI, TADEUSZ. Badania histo-cytologiczne nad kwiatami kleistogamicznemi u Lamium amplexicaule, Oxalis acetosella i Viola odorata. (Recherches histo-cytologiques sur les fleurs cléistogames chez Lamium amplexicaule, Oxalis acetosella et Viola odorata.) [Polish, with French résumé.] *Acta Soc. Bot. Poloniae* 6(3): 248-295. 3 pl., 28 fig. 1929.—It is stated that in cleistogamous flowers mechanical tissues tend to disappear from the walls of anthers. These tissues are directly penetrated by pollen tubes. Cleistogamic flowers, especially those of *Viola*, form secretory tissues that facilitate the growth of pollen tubes toward the stigma. During pollen development there appear a certain number of anomalies that end in anther degeneration. Embryos in these plants appear as a result of fertilization of the egg (contrary to Winkler's supposition for *Viola*). Cleistogamous flowers commonly degenerate.—*F. X. Skupienski (transl. by C. Perrault).*

2128. HÄRDTL, HEINRICH. Regenerationen am Laubblatt unter dem Einfluss der Schwerkraft. *Beitr. Biol. Pflanzen* 17(2): 160-199. 15 fig. 1929.—This is a study of the anatomical and histological changes appearing in petioles and leaf blades following the resection of relative portions of each. Resection is made during the earlier stages of growth and the differences between wounded and normal organs are observed 3-4 months later. In all experiments more or less regeneration of lost parts took place, depending upon the age of the organ and its relative capacity for response to stimuli. Through the formation of new tissue, enlargement of cells already present, and thickening of cell walls, the injured petiole attains nearly the size of the normal petiole. The changes are also qualitative with respect to the development of the highest degree of firmness necessary. More extensive investigation is necessary to ascertain the cause of a definite manner of reaction to resection. It is concluded that "gravity determines throughout these experiments in specific regeneration the anatomical-morphological form of the petiole and midrib."—*P. D. Strausbaugh.*

2129. HAYATA, BUNZÔ. Ueber die systematische Anatomie der Gattung Sasa Mk. et Shib. [In Japanese.] *Bot. Mag. [Tôkyô].* 43: 23-48. 1929.—The separation of the species of *Sasa* is hardly possible unless roots, stems, leaves, flowers, and fruits are at hand. This is rarely the case, and the author has undertaken to provide a means of identification in anatomy. The structure of the leaf and root of *S. borealis, S. paniculata, S. nipponica, S. albo-marginata,* and *Shibatea kumasasa* is described and illustrated in much detail. A means of separating these species is found in leaf structure. *Shibatea* is characterized by the complete lack of siliceous cells in the upper epidermis. Both *S. paniculata* and *S. borealis* lack prickly hairs on the upper epidermis; the lower epidermis of the former has such hairs but rarely whereas in the latter it is covered by them except in stomatal regions. *S. nipponica* possesses many siliceous cells in the upper epidermis; *S. albo-marginata* has almost none. —*Courtesy Japanese Jour. Bot. (transl. by J. M. Haber).*

2130. HEIDENHAIN, MARTIN. Ein vorläufiger Bericht über die Spaltungsgesetze der Blätter. Beitrag XIV zur synthetischen Morphologie. *Zeitschr. Anat. u. Entwicklungsgesch.* 90(2): 153-177. 14 fig. 1929.—Since the parts of the plant body, like the blades of leaves, are more easily studied than similar parts of animals, the author turned from zoological to botanical material in his continued attempts to discover the processes and principles of "synthetic morphology." After many years he comes to the conclusion that the true nature of the development of such animal structures as the division of the tracheal system in lungs, etc., is more easily understood by a study of compounding and dichotomous dissection so common in leaves. Various systems of dichotomy are considered and detailed studies are given of the leaves of *Juglans regia, Nigella sativa, Delphinium ajacis, Koelreuteria paniculata, Aquilegia vulgaris, Thalictrum aquilegifolium, Fagus silvatica,* and *Adiantum scutatum.* Since the segmentation-laws of leaves are found to be in harmony with the segmentation processes of various similar animal organs, it is evident that the same principles are involved in both systems.—*J. H. Schaffner.*

2131. HENRICI, M. Structure of the cortex of grass roots in the arid regions of South Africa. *Sci. Bull. Union S. Africa Dept. Agric.* 85. 12p. 3 fig. 1929.—Studies were made at Armoedsvlake, Bechuanaland, and Ermelo. Rainfall at Armoedsvlake is about 18 in., and soil moisture 4-12%. At other stations rainfall is 30-40 in. Soil at all 3 stations is deficient in phosphorus. Two types of roots occur at Armoedsvlake: corky with abundant fine rootlets, and less branched ones with a loose removable outer cortex. Rhizomes are absent in this area. The corky root contains large vessels surrounded by hard sclerenchyma. Cortex is about $\frac{1}{5}$ the diameter of the root. Small rootlets without cork function in place of root hairs. In the 2nd type the central cylinder occupies 1/10-1/4 the diameter of the root. There is less sclerenchyma, and the young roots, at first normal in appear-

ance, develop a thick cortex. Intercellular spaces appear in the center of the cortex and rapidly increase, leaving septa connecting the central cylinder with the brown exodermal layers which bear permanent root hairs. The whole spongy development takes place in a few days. Two types with loose cortex appear. One with a cortical cambium close to the endodermis, which has the power to reform the spongy layer in rainy seasons. The other lacks the cortical cambium and does not form a second loose cortex but a close corky layer instead. The loose cortex type of structure is interpreted as, probably an adaptation for water retention, although it shows a tendency to be present more frequently in one genus than another. It is not believed to be an oxygen adaptation, at least not in most cases.—*J. E. Cribbs.*

2132. **[MAGITT, M., and E. MAGITT.]** МАГИТТ, М., и Е. МАГИТТ. Этюды по анатомии хлопчатника. II: Палисадная паренхима в листке хлопчатника. **[Studies on the anatomy of the cotton plant. II. Palisade parenchyma of the leaf.]** [German summary.] Журнал Русского Ботанического Общества (*Jour. Soc. Bot. Russie*) 14(2): 191-198. 5 fig. 1929.—Leaves of American cotton are of unusual type and contain an upper palisade layer and a spongy parenchyma several cells deep. Leaves of Old World cotton have an upper and a lower (isolateral) palisade tissue, the spongy parenchyma being reduced to a very few layers of cells; the lower palisade layer is somewhat reduced. Leaves of hybrids of the American with the Old World cotton have only a single palisade layer. Cotyledons of the 2 types of cotton have only a single upper palisade layer. Plants growing in the greenhouse have a greatly reduced lower palisade layer, the extent of development being dependent on the amount of shade; the lower palisade layer is sometimes lacking. Leaves of *Gossypium stocksii, G. sturtii,* and *Althaea rosea* have an isolatral palisade structure. Those of *Abutilon avicennae* and *Ingenhousia* are of the usual type. *Hibiscus cannabinus,* like the cotton plant, is divided into 2 groups: with isolateral structure (in Egypt and Java), and with a single palisade layer (Persia). The thickness of the leaf, of the upper palisade layer, and of the lower palisade layer if present, is given for 4 principal types.—*Authors' summary (transl.).*

2133. **MÜHLDORF, A. Detasarea fructelor la Cupuliferae. [Abscission of the fruits of the Cupuliferae.]** [French summary.] *Bul. Fac. Stiinte Cernauti* 3(1/2): 38-58. 1 pl. 1929.—This paper reports the results of the author's studies of fruit abscission and fruit stalks in *Corylus avellana* L., *Castanea sativa* Mill., *Quercus robur* L., and *Fagus silvatica* L. The abscission of the achene is effected by the development of an abscission layer at the base between the achene and the cupule. The cells of this parenchymatous layer are loosened by the transformation of their walls into a pectocellulose mucilage, and simultaneously the increasing turgescence of these cells causes the rupture of the vascular strands. The abscission of the fruit-stalk takes place in three stages: (1) formation of a separating tissue associated with a cicatricial differentiation at the peduncular base, (2) breaking apart of the separating cells, and (3) cicatrization of the peduncular pod and the formation of the cicatricial periderm. These 3 stages are described in detail.—*P. D. Strausbaugh.*

2134. **MURAVIEVA, E. P. Morphologische und anatomische Unterschiede der Brassica und Sinapissamen.** [Russian, German summary.] *Ann. Essais Semences* 6(2): 129-141. 1928.—Author studied the morphological differences between *Brassica oleracea capitata, B. napus rapifera, B. campestris, Sinapis pincea,* and *S. arvensis,* dealing especially with seed coat structure, form, structure and hair production of the seed lobes and cotyledons.—*W. Crocker.*

2135. **NEWMAN, I. V. The life history of Doryanthes excelsa. Part II. The gametophytes, seed production, chromosome number and general conclusion.** *Proc. Linn. Soc. N. S. Wales* 54(4): 411-435. 3 pl., 26 fig. 1929.—The polarity and function of the nuclei in pollen grain and embryosac is determined by cytoplasmic vacuolation during the division of the microspore nucleus and after the 1st division of the megaspore nucleus. The tip of the pollen tube is continually shut off by cellulosic plugs. The egg and synergids form a filiform apparatus; polar fusion is before pollination, usually at the base of the sac; the insignificant antipodals in an antipodal pocket show slight multiplication. The "conducting tissue" of the style is not continuous with a "placenta" as such. Fertilisation and triple fusion are inferred from the presence of pollen tubes in the micropyle, normal embryo and endosperm of a known type, nucleolar appearances and chromosome counts. The chromosome number is $n=22$, $2n=44$, $3n=66$ (endosperm). The embryo is not quite Lilium-type, has lateral plumule and terminal cotyledon. The copious endosperm is a "basal apparatus" type, and retained. *D. excelsa* is concluded to be primitive among the Agavoideae group and in the family.—*I. V. Newman.*

2136. **NICOLAS, G. Remarques sur l'épiderme des feuilles de quelques Galium.** *Bull. Soc. Hist. Nat. Toulouse* 58(1): 45-46. 1929.—Epidermal cells resembling those found by Netolitzky in the lower epidermis of *G. boreale* L., *G. cruciata* Scop., *G. pedemontanum* All., *G. rotundifolium* L., and *G. rubioides* L., and regarded by him as secretory cells, were found in 11 other spp. of Galium. The "secretion" included in these cells is of uncertain chemical character, most probably a phytosterine or a related substance.

2137. **NOGUCHI, YAKICHI. Zur Kenntnis der Befruchtung und Kornbildung bei der Reispflanze.** *Japanese Jour. Bot.* 4(4): 385-403. 34 fig. 1929.—Material was fixed at frequent intervals following controlled pollinations. The pollen grain germinates immediately after reaching the stigma, and fertilization occurs 12 hours later. The synergids have started to disorganize and the polar nuclei are fusing before fertilization. The synergids disappear 24 hours after pollination; the antipodals persist for 4 days. Double fertilization occurs; 1 sperm unites with 1 of the fusing polar nuclei. The embryo and endosperm develop much as in other cereals. The embryo begins to differentiate in 4 days; the first starch is visible in the endosperm in 7 days. Some grains 7 days old will germinate, but the percentage of germination increases and the time required for germination decreases as the caryopsis nears maturity. The rates of development of the parts of the grain are shown in tables.—*P. Weatherwax.*

2138. **NYI, TSU-KIANG. Observations on the sex differentiation and flower anatomy of Firmiana simplex Wight (Firmiana platanifolia Scott and Endl., Sterculia platanifolia L. f.).** *Contrib. Biol. Lab. Sci. Soc. China* 5(3): 1-16. 9 pl. 1929.—A general study of the flowers of the Japanese varnish tree was made. Both staminate and carpellate flowers appear bisporangiate because the non-functioning organs are hardly reduced. In the staminate flower the embryo sac may reach the 7-nucleate stage before abortion. In the carpellate flowers microspores are well developed in the stamens but never germinate. All the flowers found were functionally monosporangiate. In the staminate flower the integuments and funiculus begin disintegration long before the ♀ gametophyte; the secondary sexual states of the sporophyte are thus inhibited before those of the gametophyte. The vascular supply of the functionless members is meagerly developed. The carpel is open at the beginning but the slit is soon sealed by the growth and fusion of cells on either side of the slit.—*J. H. Schaffner.*

2139. **ORECHOWA, T. A. Ueber die Technik zur Vorbereitung anatomischer Schnitte der Samen von Cuscuta. [Description of the technic for the preparation of anatomical sections of seeds of various Cuscutas.]** [Russian, German summary.] *Ann. Essais Semences* 6(2): 142-145. 1928.

2140. **PITTMAN, H. A. Note on the morphology and endotrophic mycorrhiza of Rhizanthella gardneri, Rogers, and certain other Western Australian orchids.** *Jour. Roy. Soc. Western Australia* 15: 71-79. 3 pl. 1928/1929.—*R.*

gardneri has its vegetative portions,—a rhizome bearing scales—entirely subterranean; it is devoid of chlorophyll except that a little color (purplish) may develop in the bracts and flowers. The mycorrhizal fungus, which somewhat resembles *Rhizoctonia* in mycelial characters, occurs in the outer cortical cells, and hyphae pass to the soil through epidermal hairs. Attempts to culture the mycorrhiza were unsuccessful. The underground stem of *Caladenia* spp. has a structure much like a root. An endodermis is present. Short anatomical notes are given on *Pterostylis turfosa, Prasophyllum fimbria, Diuris longifolia, Lyperanthus nigricans, Thelymitra crinita,* and *T. longifolia.*

2141. **RITTER, GEO. J. Composition and structure of the cell wall of wood.** *Indust. & Eng. Chem.* 20(9): 941-945. 17 fig. 1928.—By using sections of sufficiently small dimensions, the lignin of 3 species has been found to be divided approximately equally between the middle lamella and the remainder of the cell wall. The middle lamella lignin is more soluble in alcohol than the cell wall lignin. The optical phenomenon when bordered pits are observed between Nicol prisms is explained on the basis of the chain-like arrangement of the cellulosic material in the cell wall. When lignified and delignified wood fibers are treated with swelling reagents, the fiber walls thicken both outwardly and inwardly. The general angular cross-section area of lignified fibers is unaltered, but that of delignified fibers is changed to a circular form in which the circumference is limited by the outer layer fibrils oriented at 90° to the fiber's axis. The cell wall of wood fibers is composed of several layers which can be separated by chemical means. The layers in the cell wall of wood fibers can be separated into fibrils by chemical means. The fibrils in the outer layer extend at approximately right angles to the fiber's axis; in the remaining layers, from 0 to 30° thereto.—*Courtesy Indust. & Eng. Chem.*

2142. **SAKISAKA, M. On the number of chloroplasts in the guard cells of seed plants.** *Bot. Mag.* [*Tôkyô*] 43(505): 46-48. 1929.—[In Japanese.] The stomata of a leaf blade move simultaneously and the author therefore studied the number of chloroplasts in the guard cells which play an important rôle in the mechanism of the movement. He found relatively uniform numbers of chloroplasts in each species growing under the same conditions, but no numerical relation between related plants. An ecological study should be made.—*T. Matsumoto.*

2143. **SCARTH, G. W. The structure of wood and its penetrability.** *Paper Trade Jour.* 1928(April): (1-6). 1928.

2144. **SCHERFFEL, ALADÁR. A Lathraea squamaria L. hydathodjai és epiphyticus bacteriuma: Mycobacterium lathraeae mihi. [The hydathodes of L. squamaria, and their epiphytic bacterium, M. lathraeae.]** [German summary.] *Math. es Természet. Értesitö (Math. u. Naturw. Anz. Ungarischen Akad. Wiss.)* 45: 346-368. 3 fig. 1928.—The author describes minutely the scales of this parasitic plant, and the peculiar glands occurring on them. A large central cell functions as a water reservoir and this with adjacent cells has a bellows-like relation which regulates the pressure and volume of liquid in the cell. These glands function as hydathodes to excrete the excess water which the haustoria of the parasite draw as both elaborated and crude sap from the host. This large volume of fluid passing through the body of the parasite takes the place of a transpiration stream in terrestrial plants. The parasite metabolizes the nutritive elements of the sap removed from the host and stores excess food as starch in its scales. This transformation of sap sugar to stored starch reduces the concentration of the sap stream and hence a renewed or facilitated withdrawal of sap from the host occurs. Old scales of the parasite become less active in the elimination of water from the hydathodes due to accumulation of plugs of coagulated material in the gland pores. Much nutritive material escapes unused by the parasite and the gland cells then filled with nutritive sap derived from the host become harbors for a bacterium. This organism, *Mycobacterium* **lathraeae,** is regarded as a commensal epiphyte. The morphology and reproductive structures of this bacterium are fully described and its relationship to the other mycobacteria, e.g., *B. tuberculosis* and *B. leprae.* The umbel-like habit of branching of the chains of bacterial threads also seems to indicate a relationship with *Cladothrix* and *Leptothrix* and hence possibly a connection with Actinomyces.—*H. H. M. Bowman.*

2145. **SINGH, T. C. N. A note on the presence of a sporangium on the indusium of Cheilanthes albo-marginata.** *Jour. Indian Bot. Soc.* 8(3): 207. 1 pl. 1929.—The sporangium was normal.—*W. Dudgeon.*

2146. **SOLEREDER, HANS, und FRITZ JURGEN MEYER. Systematische Anatomie der Monokotyledonen. [Systematic anatomy of monocotyledons.]** *Heft* 4. 176p. 65 fig. Gebrüder Borntraeger: Berlin, 1929.

2147. **SOUÈGES, RENÉ. Embryogénie des Légumineuses. Les derniers stades du développement de l'embryon chez le Trifolium minus Rehl. [Final stages in embryogeny of T. minus.]** *Compt. Rend. Acad. Sci. [Paris]* 184(20): 1196-1198. 1 fig. 1927.

2148. **STEHLI, G., und E. KOLUMBE. Die Botanische Mikrotechnik. Ein Leitfaden der botanisch-mikroskopischen Arbeitsmethoden, zugleich eine Einführung in die Pflanzenanatomie. Part XII of: Handbuch der mikroskopischen Technik.** 75 p. 96 fig. Franckh'sche Verlagshandlung: Stuttgart, 1929. Pr. 3. 60 M.—This little book, intended for beginners, is a brief introduction to botanical microtechnique, with a study of the cell and tissues. The technique includes directions for making preparations of living material and material which needs no imbedding. There are formulae for fixing agents and stains, directions for imbedding in paraffin, celloidin and in a combination of paraffin and celloidin, and some hints on the use of the microtome. The second part presents a series of forms from the algae to the higher plants and an introduction to some phases of anatomy.—*C. J. Chamberlain.*

2149. **SVENSSON, HARRY G. Zytologische-embryologische Solanazeenstudien. I. Über die Samenentwicklung von Hyoscyamus niger L.** *Svensk Bot. Tidskr.* 20(3): 420-434. 6 fig. 1926.—The ovule has 1 massive integument. An 8-nucleate embryosac of the usual type develops from the innermost of 4 megaspores; the antipodals soon degenerate. Haploid chromosome number is 18. Double fertilization evidently occurs. At the 1st division of the primary endosperm nucleus a wall divides the sac into 2 compartments: in the smaller, micropylar one several free nuclei are usually formed, after which cellular tissue develops; sometimes there is no free-nuclear stage. In the other compartment free nuclei become numerous in the parietal cytoplasm and cellular endosperm later develops in the usual manner. Rarely the whole endosperm is cellular from the start. The endosperm development of *Hyoscyamus* stands between that of *Schizanthus* (free-nuclear) and that of *Datura* and *Nicotiana* (cellular). Diversity in endosperm development does not indicate lack of homogeneity in the Solanaceae.—*L. W. Sharp.*

2150. **TATEISHI, SHINKICHI. Embryologische Studien an der Gattung Chrysanthemum.** *Japanese Jour. Bot.* 4(4): 317-326. 2 pl., 6 fig. 1929.—The paper deals with the origin and development of the embryosac of several species of *Chrysanthemum,* principally *C. morifolium* var. *sinense.* Two complete tetrads are often formed in a single nucellus, and, occasionally, 2 embryosacs are developed. As many as 6 embryosac mother cells were noted. In 13 of the 15 spp. more than 1 embryosac mother cell occurs rather frequently. The antipodals present considerable variety in form and number (2-11), the form varying from the usual shape to a much inflated condition in the antipodal nearest the chalaza. The multinucleate condition is frequent in all the antipodals.—*C. J. Chamberlain.*

2151. **TIWARY, N. K. Further observations on the seeds and seedlings of Eugenia jambolana Lamk.** *Jour.*

Indian Bot. Soc. 8(1): 82-85. 2 fig. 1929.—Hundreds of seeds and seedlings were examined over a period of 8 years. One seedling bore 1 massive cotyledon, without trace of a 2nd. The plumule of another seedling had penetrated one cotyledon, while the radicle had penetrated the other.—*W. Dudgeon.*

2152. **UFER, MAX.** Die Unterscheidung von Rot- und Schafschwingel. [Distinction between red and sheep's fescue grass.] *Fortschr. Landw.* 2(24): 798-806. 5 fig. 1927.—Leaf cross sections furnish the chief basis for distinction, though it is not determined how far the variability of the species complicates this. From one habitat, 3 types, known as the *Festuca rubra, F. ovina* and *F. ovina-sulcata* types, were determined. Transition forms between the *ovina* type and the *ovina-sulcata* type occur, but the *rubra* type is nearly isolated. Sections must be made from the central part of leaves corresponding in position.—*From author's abstract (transl. by H. D. Hill).*

PALEOBOTANY

EDWARD W. BERRY, *Editor*

(See also in this issue Entries 36, 2178, 2179, 2181, 2185, 2189, 2190, 2193)

2153. **BERRY, EDWARD W.** A Bothrodendron from Bolivia. *Jour. Washington Acad. Sci.* 21(13): 295-298. 2 fig. 1931.—The material observed was not sufficient to warrant giving a specific name. Very similar to *Cyclostigma kiltorkense* Haughton of Europe, and *Cyclostigma australe* Feistmantel of Australia. Probably of Up. Devonian.

2154. **CARPENTIER, ALFRED.** Divers modes de conservation des plantes Wealdiennes. [Various methods of fossilization of Wealden plants.] *Ann. Soc. Sci. Bruxelles* 49(2/3): 144-146. 1929.

2155. **CHENEY, L. S.** Wisconsin fossil mosses. *Bryologist* 33(5): 66-68. 1930.—Several species have been identified from brown peat layers in a bog near Solon Springs and from the "Wisconsin forest bed" along Lake Michigan. Both beds are probably of late preglacial or early post-glacial origin.—*A. M. Taylor.*

2156. **COATES, HENRY.** Note on Carboniferous fossils from Dollar. *Trans. and Proc. Perthshire Soc. Nat. Sci.* 9(1): 30-31. 1 pl. 1929/30(1931).—The ferns *Mariopteris nervosa** and *M. muricata**, and the echinoderm *Cidaris* sp.*, new to Perthshire.

2157. **DUERDEN, H.** On the preparation of cellulose films of fossil plants. *Ann. Botany* 45(178): 376-378. 1931.—A modification of Walton's method (1928) of sectioning fossil plants contained in petrifactions. A plasticiser (castor oil, triacetin, or benzyl abietate) is added to the cellulose acetate or cellulose nitrate solution, to avoid "puckering" of the sections due to unequal drying. Among other plasticisers and films, pyroxylin dissolved in equal parts of alcohol and ether, plus 5% castor oil, gives good results.

2158. **[FOMICHEV, V. D.]** ФОМИЧЕВ, В. Д. Предварительный отчет о геолого-разведочных работах в Кемеровском районе Кузнецкого бассейна в 1928 г. (Район дд. (Region of Mazurova and Ishanova villages.)]** [English summary.] Известия Главного Геолого-Разведочного Управления (*Bull. Geol. & Prospecting Service, USSR.*) 49(3): 53-73. 2 pl., 1 fig. 1930.—Plant impressions of the Gondwana type are reported from throughout the prospected series. Occurrence of a fossil tree trunk of the type of *Mesopitys tschihatcheffi, Cordaites equalis, Neuroganganopteris cardiopteroides,* and a fauna of pelecypods are noted.

2159. **GROUT, A. J.** A fossil form of Drepanocladus fluitans Jeanbernati (Ren.) Grout. *Bryologist* 33(3): 33. 1930.—A well preserved specimen from Kansan drift of Iowa, or from a pocket in earlier but closely related deposits about 15 ft. below the surface.—*A. M. Taylor.*

2160. **HEARD, ALBERT, and JOHN FREDERICK JONES.** A new plant (Thallomia), showing structure, from the Downtonian Rocks of Llandovery, Carmarthenshire. *Ann. and Mag. Nat. Hist.* 7(42): 580. 1931.—**THALLOMIA,** type *T.* **llandyfriensis,** L. Downtonian, probably above Up. Ludlow.

2161. **HÖEG, OVE ARBO.** A psilophyte in South Africa. *Kgl. Norske Vidensk. Selsk. Forhandl.* 3(paper 24): 92-94. 1 fig. 1930(1931).—**DUTOITIA** (p. 92) (affinity *Psilophytales*), with *D.* **pulchra*** (p. 93), in blue clayish shale exposed along the road from Knysna to Port Elizabeth, belonging, in all probability, to the Lower or Middle Devonian.

2162. **HOLDEN, H. S.** Some wound reactions in Ankyropteris corrugata. *Proc. Linnean Soc. London* 142. 65-66. 1929/30(1931).—Abstract.

2163. **LEDOUX-MARCELLE, HUBERTE.** Sur les flores du Dévonien de la Belgique. II. Pinakodendron corneti Ledoux-Marcelle, nov. sp. *Bull. Soc. Belge Géol. Paléont. et Hydr.* 40(2): 101-106. 1 pl. 1931.—*P.* **corneti*** (p. 104), Coblenzian, with discussion of the validity of the genus.

2164. **LOUBIÈRE, A.** Observations sur l'Odontopteris obtusa de Brongniart. *Bull. Soc. Bot. France* 76(9/10): 1080-1082. 1929.—Figure 3, plate 78, of Brongniart's Histoire des végétaux fossiles is a correct interpretation of the type, in contradiction to Zeiller who claimed that the figure more nearly represents *O. lingulata* Goepp. This latter species is neuropteroid. Zeiller's revised figure is also neuropteroid and is not a true reproduction of Brongniart's original.—*C. A. Arnold.*

2165. **LOUBIÈRE, A.** Sur les graines et les feuilles stipales associées à l'Odontopteris obtusa Brongn. dans le terrain carbonifère de Carmaux. *Rev. Gén. Bot. [Paris]* 42(498): 321-326. 1 fig. 1930.—Radially symmetrical seeds, *Odontopterocarpus* **oblongus*** (p. 323), and cyclopteroid appendages, *Cyclopteris* **blayei*** (p. 325), were found in association with pinnae of *Odontopteris obtusa** from the L. Stephanian of Carmaux. The pteridospermous nature of the genus *Odontopteris* is affirmed.—*C. A. Arnold.*

2166. **PETRASCHECK, W.** Kohlengeologie der Österreichischen Teilstaaten. II. Teil. pp. 273-484. 12 pl. *Kattowitzer Buchdruckerei u. Verlags-Sp. Ak. Katowice,* 1926/29.—Detailed description of the following coal districts: The outer Alpine basin in Austria (Tertiary), the Alpine coal in Austria and Italy (Carboniferous, Triassic, Jurassic, and Cretaceous), the Dinaric Mountains in Yugo-Slavia and Italy (Tertiary), the coal district of Ostrau-Karwin-Krakau in Poland and Czechoslovakia (Carboniferous), the brown coal of Bohemia and Little Poland (Tertiary). The description is based on numerous investigations and reviews of the newest mining results. In all the coal regions the stratigraphy, tectonics, character of the coal, and index fossils are discussed. Many new fossil finds are thus noted. The dependence of the character of the coal on geological and biological factors was investigated in each region. The book ends with a large, comprehensive bibliography of the geology of coal in the old Austrian Empire.—*W. Petrascheck (transl. by B. F. Howell).*

2167. **POTONIÉ, R., und H. HELLMERS.** Zur Entstehung der Gerinnungskörper (der sogenannten Algen) der Bogheadkohlen und- schiefer. **[Formation of concretions (so-called algae) in boghead coal and slate.]** *Jahrb. Preuss. Geol. Landesanst Berlin* 48: 152-157. 4 fig. 1927(1928).

2168. **PRINCIPI, P.** Florula quaternaria di Magliano de'Marsi sull'orlo della conca fucense. *Atti R. Accad. Naz. Lincei Rend. Cl. Sci. Fis. Mat. e Nat.* 13(3): 211-212. 1931.—Leaf imprints in lacustrine deposits of

argillaceous sand or sandy clay intercalated in conglomerate, outcropping near Magliano de' Marsi, Italy, include: *Carpinus betulus, Corylus avellana, Alnus glutinosa, Alnus* sp., *Fagus sylvatica, Quercus robur, Q. cerris, Castanea sativa, Salix alba, Ulmus campestris, Acer pseudoplatanus,* and *Rhamnus* cfr. *frangula.* They indicate that the flora is Quaternary.

2169. SCOTT, H. H. Tasmanian Cycadophyta. *Papers and Proc. Roy. Soc. Tasmania* 1930: 90-93. 3 pl. 1931.—*Cycadites* **dowlingi*** (p. 90), from Launceston Tertiary Basin; regarded as intercalates from the Mesozoic strata. The 6 cotypes include stem, bud, and cone.

2170. SEWARD, A. C. Plant life through the ages. A geological and botanical retrospect. 601p. 140 fig. including 9 reconstructions of ancient landscapes drawn by Edward Vulliamy. Macmillan Co.: New York, 1931. Pr. $10.—This book is intended primarily for readers possessing no botanical or geological knowledge: the author avoids unnecessary technical terms and explains such as are essential. Certain parts of the book, e.g., tables of distribution of plants over the world, the bibliography and references to original sources, are included for the benefit of students. The aim has been to cater for both types of reader, the layman who has a general interest in geological and botanical history and the student of botany and geology. The first 6 chapters deal with the earth's crust and the nature of the evidence on which geologists base their reconstructions of past scenes. After a short account of the preservation of plants as fossils and a concise description of the various groups and families of plants, the author traces the history of the plant-world from the time of the oldest rocks which contain recognizable remains of plants to the present day. An attempt is made to correlate successive stages in the evolution of floras with the corresponding climatic and physical environment in which the plants lived. Chapter 7 is devoted to the earliest records of plant life in the preCambrian. The author maintains a conservative attitude toward the so-called Algonkian calcareous algae described by Walcott and others and is inclined to consider them as concretionary instead of organic. He is less conservative toward the hypothesis that seaweeds became terrestrial plants by emergence of the sea floor, although he does not commit himself definitely. Chapter 8 is devoted to the Cambrian, Ordovician, and Silurian periods and is mainly geological although it includes a brief but satisfactory account of living and extinct algae. Cryptozoon is regarded as probably inorganic in nature and the author advocates the use of the term Protophyceae for fossil remains that appear to be indubitable algae but whose systematic position is problematic. Chapter 9 is devoted to the Devonian period and since this time marks the presence of land plants in any considerable number and variety, considerable space is devoted to a discussion of the Devonian terrestrial plants, particularly the group known as the Psilophytales. Chapter 10 is primarily a geological summary of the Carboniferous and Permian periods and includes an extended discussion of the age of the late Paleozoic glaciation. In Chapter 11 the earlier Carboniferous plants receive consideration and Chapter 12 gives a similar summary of the later Carboniferous and Permian plants, including a discussion of the provincial floras of the later Paleozoic, particularly the so-called *Glossopteris* flora, with interesting speculations on the geography, climate and correlation of the fossiliferous beds. Chapter 13 is devoted to the Triassic. The author rather overemphasizes the floral contrast between the Paleozoic and Mesozoic and the desert character of Triassic environments. He accepts the form genus *Sagenopteris* as the probable foliage of the Caytoniales, thinks *Thinnfeldia* may be a pteridosperm and mentions the genus *Fraxinopsis* from the late Triassic of Argentina as a possible dicotyledon. Chapter 14 is devoted to the Jurassic and includes a discussion of the supposed primitive order Caytoniales. In connection with a supposed dicotyledonous leaf from the Rhaetic of east Greenland, attention is called to similar remains from the Stonesfield slate of England. Chapter 15 is devoted to the Cretaceous, the new era of the gradual dominance of flowering plants, and the floras of the Wealden and Arctic Cretaceous are singled out for special emphasis. Chapter 16 summarizes the more general features of Tertiary floras, their distribution and climatic significance. Chapter 17 is a brief summary of Quaternary plants and their environments. The last Chapter is devoted to a general summary of the book with especial reference to the evolution of structural features, flowering plants, extinct arctic floras and climates of the past, followed by an exceedingly useful bibliography.—*E. W. Berry.*

2171. SZEPESFALVI, JÁNOS. További adatok az Alföld fosszilis flórájához. [Further contributions to the fossil flora of the Great Hungarian Plain.] [Hungarian and German text.] *Magyar Bot. Lapok.* 29: 4-13. 1930.—Treats the flora of a fossil peat, mainly consisting of the mosses *Scorpidium* and *Drepanocladus,* similar to the recent swamp flora of north Europe.—*C. Schermann.*

2172. WILLIAMS, R. S. Pleistocene mosses from Minneapolis, Minnesota. *Bryologist* 33(3): 33-36. 1 pl. 1930.—Descriptions of: *Calliergon giganteum** (Schimp.) Kindb., *Drepanocladus* **minnesotensis*** (p. 33), and **NEOCALLIERGON** (p. 34), with *N.* **integrifolium*** (p. 36).—*A. M. Taylor.*

2186. JONES, W. F., and W. L. WHITEHEAD. Cretaceous-Eocene unconformity of Venezuela. *Bull. Amer. Assoc. Petrol. Geol.* 13(6): 617-625. 2 maps. 1 pl. 1929.—Asserts that there exists in this part of Venezuela a brackish and fresh water fauna and flora of Eocene age; and records the brachiopod *Productus,* the bryozoan *Fenestrella,* and a gastropod of the family Euomphalidae from the adjacent Carboniferous limestones.—*D. J. MacNeil.*

2187. LANQUINE, ANTONIN. Le lias et le jurassique des chaines provencales. Recherches stratigraphiques et paléontologiques. I. Le lias et le jurassique inférieur. *Bull. Serv. Carte Géol. France et Topogr. Souterr.* [*Paris*] 173: 1-385. 20 pl., 16 fig. 1929.—This paper deals with the stratigraphy and paleontology of the Bajocian and Oxfordian of the mountainous country extending from south of Digne to the Mediterranean and from west of Marseilles and Aix to the lower valley of the Var. A preface treats the geomorphologic and tectonic features. There is a bibliography of the Provençal Jurassic, and one for the preface. Local stratigraphic observations with paleontologic lists are presented. More than 800 Liassic and lower Jurassic spp. were studied. All from marine deposits. The Lias is represented entirely by deposits of the neritic zone. The lower divisions have their best representation in the eastern Varoise. The Sinemurian is found only close about Castellane and Aix. The middle and upper Lias is absent throughout the eastern Varoise. The lower Jurassic is represented by formations of the neritic zone, zoogenic in origin, in the eastern regions, and by formations of the bathyal zone in the western region, the intermediate regions present, particularly in the Mediterranean portions, bathyal formations interfingering below and above with neritic deposits.—*A. Lanquine (transl. by J. W. Monahan).*

2188. MATĚJKA, ALOIS. Geologické Studie z Okolí Ružomberka na Slovensku. [Geological explorations in the vicinity of Ružomberok, Slovakia.] *Sborník Státního Geol. Ústavu Ceskoslovenské Republ.* (French résumé.) 7: 529-575. 8 pl. 2 fig. 1927.—Lists from Slovakia: from the Cretaceous Carnian and Norian 4 brachiopods, 6 pelecypods, and 1 gastropod; from the Ladinian dolomite 1 foraminiferan, 3 echinoids, 1 crinoid, 1 brachiopod, 2 pelecypods, and 1 gastropod; from the Paleogene foraminiferans, radiolarians, 11 echinoids, 2 crinoids, 1 scaphopod, 3 chaetopod worms, 3 brachiopods, 4 pelecypods, and 2 eucrustaceans.—*F. Anderegg.*

2189. PALMER, R. H. Geology of Southern Oaxaca, Mexico. *Jour. Geol.* 36(8): 718-734. Map. 1928.—Remarks that the Lower Jurassic and Upper Pleistocene of this Mexican region have an abundant, well-preserved, flora, and that the Turonian Cretaceous carries the lamellibranchs *Apricardia* and *Radiolites* and Foraminifera.—*D. J. MacNeil.*

2190. REESIDE, JOHN B. Jr. Triassic-Jurassic "Red Beds" of the Rocky mountain region: a discussion. *Jour. Geol.* 37(1): 47-63. 1 fig. 1929.—States that in this Triassic and Jurassic region there are vertebrate and fresh-water invertebrate remains, including the pelecypods *Unio* (Jurassic) and *Daonella* (Triassic), dinosaur tracks, and indeterminate plant fragments.—*D. J. MacNeil.*

2191. SCHINDEWOLF, O. H. Die Liegendgrenze des Karbons im Lichte biostratigraphischer Kritik. *Compte Rend. Congrès Avanc. Études Strat. Carbonifère, Heerlen, 1927.* 651-661. 1928.—Since the racial development of different groups of organisms is not synchronized, the boundary between geologic systems should be drawn at various horizons depending on which groups of fossils are taken as a criterion. The author proposes to give the decisive rôle in each case to that class of

animals which was at the time most vigorous, and preferably one which can be used for minute zoning. Accordingly the cephalopods are relied upon to establish the Devono-Carboniferous boundary, which falls at the top of the *Gattendorfia* beds.—*O. H. Schindewolf (transl. by C. O. Dunbar).*

Pologne)* 3(3/4): 382-433. pl. 14 & 15. 1 fig. 1926.—Records many fossils from this part of Poland. From the Jurassic, brachiopods, cephalopods, echinoids, and crinoids; and from the Cretaceous, sponges, worms, crinoids, echinoids, a bryozoan, brachiopods, pelecypods, cephalopods, gastropods, and fishes. Among these fossils are the sponge *Siphonia*, the echinoderms *Apiocrinus, Discoidea minima, Echinoconus ellipticus, Micraster cortestudinarium, Offaster pilula,* and *Ananchytes corculum,* the pelecypod *Inoceramus libiatus,* and the cephalopods *Acanthoceras rhotomagense, Schloenbachia coupei, Baculites baculoides, Scaphites aequalis, Actinocamax westfalicus, A. granulatus, A. verus, A. quadratus, Belemnitella mucronata, B. m.* var. *junior, Pachydiscus oldhami, P. egertoni,* and *P. stanislavopolitanus.* Bibliography.—*D. J. MacNeil.*

2193. **VANDERPOOL, H. C. A preliminary study of the Trinity Group in southwestern Arkansas, southeastern Oklahoma, and northern Texas.** *Bull. Amer. Assoc. Petrol. Geol.* 12(11): 1069-1094. 5 fig. 1928.—Foraminifera occur sparingly; ostracods are plentiful, including the undescribed "new species" *Bairdia dorsoventrus, Bythocypris rotundus, Cytheridea trinitiensis* and *Paracypris weatherfordensis;* and pelecypods, gastropods and the stonewort, *Chara,* are also present in this Lower Cretaceous formation.—*D. J. MacNeil.*

2194. **VAUFREY, RAYMOND. Le Paléolithique italien.** *Arch. Inst. Paléontol. humaine. Mem.* 3. 196p. 7 pl. 54 fig. [Masson et Cie: Paris]. 1928.—Traces of Early Paleolithic, Middle Paleolithic, and Late Paleolithic man are found in Italy. Early Paleolithic Acheulean implements occur at Venosa, formed apparently during the early part of the last interglacial epoch; and Chellean artifacts have been found at Capri that were probably made at about the beginning of that epoch, the true mammoth being at this place strangely associated with the hippopotamus and Merck's rhinoceros. Cultural evidences of the existence of Mousterian man are present in the Roman Campagna, and a Neanderthal cranium has recently been discovered there. The fauna found accompanying the Mousterian flints in Italy differs from place to place: at Grimaldi and in southern Italy there have been unearthed the bones of warm climate species, in the intermediate region Merck's rhinoceros alone survived from the ancient fauna, whereas north of the Po are found the remains of a cold climate fauna. It seems that during the Mousterian a cold climate fauna gradually penetrated the Italian peninsula; and in the Late Paleolithic this fauna was fully established in the peninsula, with the reindeer at Grimaldi, the glutton, the varying hare, and the snowy owl in the Riviera, and the mammoth, rhinoceros, asses, and the great auk in the Otranto country. The only Late Paleolithic culture represented is an Aurignacian one, here denominated the Grimaldian, with its type bed the upper one of the Grotto of Grimaldi. In Sicily there is no trace of a Mousterian culture, man having apparently not reached that island until very late in the Paleolithic. If there was a Sicilian-Tunisian isthmus in existence during the rest of Paleolithic time (a comparison of the African and Sicilian faunas indicates that there was none) it had not been invaded by man. The culture found in Sicily is an impoverished Grimaldian one. The Campignian of Italy forms an amalgam of other cultures. The memoir ends with a summary of prehistoric research in Italy, a bibliography of 205 titles, and a bibliographic index; and charts show the subdivisions of the Paleolithic and of the Campignian.—*R. Vaufrey (transl. by B. F. Howell).*

2195. **WHITNEY, FRANCIS LUTHER. Bibliography and index of North American Mesozoic Invertebrata.** *Bulls. Amer. Paleontol.* 12(48): 46-494. 1928.—This work is supplementary to C. B. Boyle's similar bibliography of 1893. In Part I a list of authors, with citation of their papers, is given. In Part II the genera and species described between 1892 and 1922 are listed alphabetically and the references to the literature are given. In a few special cases species that have not been actually published, but have been figured or otherwise referred to in the literature, are included. No attempt has been made to emend any of the generic and specific names.

Chir.* 26(2): 231-234. 1930.—In adult rabbits, the presence and necrosis of bone is not necessary for the successful grafting of periosteum, or for the development of new bone and cartilage.

2204. **ROLLET, JACQUES. Recherches histologiques sur les greffes testiculaires chez les mammifères (Rat blanc).** *Compt. Rend. Acad. Sci.* [*Paris*] 184(13): 839-841. 1927.

2205. **SUPINO, FELICE. Casi di rigenerazione di arti in Axolotl. [Regeneration of joints in axolotl.]** *R. Ist. Lombardo Sci. e Lettere, Rend.* 62(6/10): 196-198. 1 fig. 1929.

2206. **WILLIAMS, STEPHEN C. Regeneration of peripheral nerves in Amphibia studied with the aid of a vital stain.** *Jour. Exp. Zool.* 57(1): 145-181. 4 pl. 1930.—Application of 1% methylene-blue solution to the punctured surface of the tail fin of amphibian larvae stains the axis cylinders of living nerves. Beaded filaments and tapered points constitute the nerve endings. General cutaneous and lateral-line nerves in *Rana sylvatica* and *Hyla crucifer* at room temp. invariably showed degeneration following section. Regeneration was studied in 61 cases. Axones entering the degenerated sheath beyond the lesion show an average growth rate of 8.5 μ per hour; those failing to enter grow only 2.95 μ per hour. The observations do not support the view that sectioned peripheral nerves in Amphibia may heal by first intention.—*Author* (*courtesy Wistar Bibl. Serv.*).

2207. **ZAJEWLOSCHIN, M. N., und J. CH. KOCH. Über die Regeneration des elastischen Knorpels.** *Arch. Klin. Chir.* 161(1/2): 157-171. 10 fig. 1930.—In each of 11 rabbits, an incision was made into the cartilage of one ear; a piece of cartilage about 0.5 by 1 cm. removed from the other. Tissues were removed for study at intervals from 7 days to 12 mos. after operation. Both degenerative (beginning immediately after the infliction of the trauma) and regenerative (beginning about a month after the injury) changes occurred. The perichondrium is the important factor in regeneration. At the beginning of regeneration the cartilage had no elastic fibers; but assumed a more typical aspect later.

GROSS ANATOMY (EXCEPT PRIMATES)

2208. **ARTEMENKO, B. A. Über die morphologische Bedeutung des M. transversus costarum.** *Anat. Anz.* 68(11/14): 248-255. 5 fig. 1929.—After studying the origins and relations of the M. transversus costarum. M. obliq. abdom. externus and M. rectus abdominis of *Phoca hispida caspica, Meles meles, Canis familiaris, Erinaceus europaeus, Pteropus edulis, Oryctolagus cuniculus, Lepus europaeus,* and *Gazella subgutturosa,* the author concludes that the M. transversus costarum is independent of the M. rectus abdominis and represents the cranial portion of M. oblig. abdom. externus.—*R. R. Best.*

2209. **BARGE, J. A. J. Zur Morphologie der Lippe. 1. Über Lippenbildung bei den Reptilien.** *Zeitschr. Ges. Anat. Abt. 1. Zeitschr. Anat. u. Entwicklungsgesch.* 82: 694-719. 21 fig. 1927.—Reptiles possess lips, of the type found in mammals, in which the labial and gingival structures are separated by a vestibulum oris. The development of the lips, however, varies greatly in degree. Crocodilia and Chelonia have no true lips. A raised edge of mucous membrane covering the teeth, without a vestibulum oris, is found in the upper jaw of *Varanus chlorostigma, V. salvator, V. elegans, V. bivittatus, Tejus ameiva, Pseudopus apus, Euprepes ernesti, E. sebae, Lygosoma cyanurum, Anguis fragilis, A. punctatus,* and in both jaws of the Geckonidae. A broad shelf, without the groove characteristic of a vestibulum oris, is lateral to the teeth of *Tupinambis.* Many reptiles possess what may be termed a pseudovestibulum oris, a deep groove between the row of teeth and the edge of the mouth, but no gingival tissue covers the surface of the jaw. This condition is found in upper and lower jaws of *Hatteria punctata,* and many Agamidae. A pseudovestibulum may be found in association with a true vestibulum oris. This occurs in the lower jaw of *Hatteria punctata, Calotes jubatus, Bronchocoela jubata, Draco lineatus, D. fimbriatus, D. viridis, Uromastix azureus, Agama colonorum;* in the upper jaw of *Draco volans;* and in both jaws of the Chamaeleonidae. A true vestibulum oris, without a pseudovestibulum, is found in the lower jaw of *Varanus chlorostigma, V. elegans, V. salvator, V. bivittatus, Tejus ameiva, T. murinus, Euprepes ernesti, E. sebae, Bothrops alternatus;* both jaws of *Scincus* sp., *S. multifasciatus, Polychrus marmoratus, Iguana sapidissima, Tropidonotus natrix, Python* sp. Development of a vestibulum oris and true lips is usually associated with the presence of numerous labial glands. It is suggested that a relationship exists between the evolution of the 2 sets of structures. Probably the mammalian lip is a further development of the reptilian lip.—*L. E. Griffin.*

2210. **BÖKER, HANS. Flugvermögen und Kropf bei Opisthocomus cristatus und Stringops habroptilus.** *Jahrb. Morph. u. Mikrosk. Anat. Abt. 1, Gegenbaur's Morph. Jahrb.* 63(2): 152-207. 33 fig. 1929.—The paper deals with the mode of flight in parrots and the relation of a bird's flying ability to its feeding habits and to the structure of the crop. The practical loss of ability to fly in *Stringops* and the peculiar mode of flight in *Opisthocomus* are intimately related to the peculiarities of the large crops in these birds. A study of an anatomical series and of the development of *Opisthocomus* leads to the conclusion that this relation must have become effective step by step in the phylogenetic history until the extremes found in *Opisthocomus* and *Stringops* were produced. The mode of flight in *Opisthocomus* is very primitive and without elevating powers or endurance. Gliding probably is never attempted. *Stringops* practically has lost all ability to fly and is becoming a walking bird. All other parrots are flyers of differing lifting powers, endurance, and versatility. In *Opisthocomus,* feeding on the hard leaves of certain plants, a strong musculature and a hard epithelium developed in the crop. The full crop disturbed the body equilibrium and reduced the flying and gliding power. The balance was partly restored by the crop moving towards the sternum and here it disturbed the development of the crista sterni and the breast musculature, thus reducing the lifting power of the wings. *Stringops* descended from good flyers but a group handicapped by a short tail and a large crop. They were compelled to seek their food on the ground and this led to the neglect of flying and to the development of walking habits. In this group the breast musculature did not have to counteract the disturbance caused by a caudal migration of the crop. The facts presented show that life conditions

and habits call forth characteristic changes in anatomical structure so far as the reaction capacity of the organism permits. This results in a structural struggle or readjustment which in turn induces changes in life habits. The important acquired anatomical changes become inheritable and fixed. Direct causation is the most important factor in species transformation; inner factors—orthogenetic—add their part. Mutations play an entirely subordinate rôle. If the structural changes are favorable the species continues but if they lead to unfavorable consequences, selection may annihilate the whole group. —*H. F. Nachtrieb.*

2211. **DABELOW, A. Über Korrelationen in der phylogenetischen Entwicklung der Schädelform. I. Die Beziehungen zwischen Rumpf und Schädelform.** *Jahrb. Morph. u. Mikrosk. Anat. Abt. 1. Gegenbaur's Morph. Jahrb.* 63(2): 1-49. 27 fig. 1929.—The form of the skull appears to depend upon more factors than does any other part of the skeleton. The object of these studies is to examine the material from various sources and with the aid of new contributions determine the limitations and correlations of the several factors suggested as affecting the changes of the skull. The first part deals mainly with the limitation of the applicability of Weidenreich's correlation between the base of the skull and body position. According to this correlation the base of the skull becomes lordosic when the vertebral column approaches the skull from above and it becomes kyphosic in the reverse condition. The details of sagittal sections through the head and trunk, including the brain and spinal cord, of *Phocoena* show that the above correlation undoubtedly exists here. A comparison with primordial crania indicates that the posterior section of the "neural skull" remains stationary while the visceral portion moves upward and with it the forebrain and the portions of the base of the skull in front of the sella turcica. The related changes can be determined objectively only, when in mammals, the bending of the neural tube between the atlas and foramen magnum is brought into the same position in all the forms compared since this is the only bend that remains unaffected by all the changes in structure. This method makes clear that the portion of the base behind the sella turcica, the larger part of the clivus, always has approximately the same position relative to the spinal cord and body axis. Only the portion of the skull in front of this changes and mostly in connection with shiftings of the visceral skeleton. Erecting or depressing the body, kyphosis or lordosis of the cervical vertebrae, will not of itself necessarily produce the characteristics noted first. Lordosis of the base is not always conditioned by a certain position of the body. It is independent of body position in the marsupials and those animals beneath them in the system. This type of base lordosis can not be adjusted or converted into a kyphosis through the erection of the body, for the kangaroo and the decidedly erect owls possess a "skull-base-lordosis." A bend like that of the embryos and fetuses of other mammals would so hide the mouth opening between the trunk and the head that the embryonic marsupial could not attach itself to the nipple in the marsupium. This attachment is made possible by an upward, dorsal bend of the visceral portion. Since lordosis of the base below the marsupials generally is independent of the body position it probably is conditioned by the more primitive form of the brain. The degree of base kyphosis does not depend upon the degree of body erectness. The slightly erect *Semnopithecus* has a distinct kyphosis while the more decidedly erect kangaroos and the birds have retained a lordosis. The erection of the skull base (in cases of horizontal palates) also is not parallel with the degree of erection. In animals moving horizontally it can ascend more decidedly than in more erect animals (baboon, gibbon). Finally, in horizontally placed animals it may decrease forward in some (*Mycetes*) and in others drop forward decidedly (baboon). The shiftings in the region of the cranium, when the neck flexures of the neural tube are taken into account as above, can be made particularly evident in a comparison of the position of the corpus callosum and the pons; furthermore, in the changes in the size of an angle whose vertex in a sagittal section is at the deepest point of the pons and whose sides are formed by connecting this point with the highest point of the curve of the corpus callosum and a point in the middle of the medulla at the anterior border of the atlas. The posterior side retains its position in reference to the medulla while the anterior shifts in relation to the body position.—*H. F. Nachtrieb (from summary).*

2212. **DOMBROWSKI, BRONISLAW. Der Suspensorialapparat der Ichthyopsiden.** *Zeitschr. Ges. Anat. Abt. I. Zeitschr. Anat. u. Entwicklungsgesch.* 82(6): 643-656. 9 fig. 1927.—The suspensorium of the Ichthyopsida presents 2 types:—"Autostyle" type in which the quadrate (or the corresponding part of the palato-quadratum) serves as a suspensorium in the author's Gnathotheria and Teleostomata (Holocephali, Dipnoi, Amphibia, Notidanidae), animals with "intensive" jaw function and a terminal mouth. "Hyostyle" type in which the "hyomandibulare" serves as a suspensorium in the author's Pneumatotheria and Hypostomata (sharks, Chondrostei), animals with well developed respiratory apparatus and a corresponding weak structure of the maxillary apparatus. Teleostei belong to type 2 but must be considered separately. Both types are built on the same plan, possessing an "epi-element" that is connected with the skull by 3 processes. They differ in function and structure. The jaw suspensorium functions as a support and usually has all 3 processes and its cover-bones fused with the skull. The hyoidal suspensorium, affected by energetic movement, loses most of its medial connection with the skull and retains either both or only one of the lateral processes and its cover-bones do not fuse with those of the skull. The Selachii have the simplest hyostyle suspensorium. That of the Holostei-Teleostei is close to this in structure. That of the Chondrostei can be derived from that of some of the Selachii and that of *Protopterus* may be considered as a changed or complicated form of that of the Chondrostei or Holostei-Teleostei. The noted peculiarities of the suspensorial apparatus may be divided into those of phylogenetic and those of functional significance. Only a very small number of the characters have a phylogenetic significance, most of them are distinctly of a functional nature. The Gnathotheria and Pneumatotheria in general, corresponding to the Pisces and Tetrapoda, are functional, not phylogenetic groups. The Teleostomata almost coincide with the Teleostomi and the Hypostomata with the Plagiostomi. The anatomical characteristics of the great systematic groups of animals have a distinctly functional character. This may not always be apparent because these "tectonic" characters become obscured by later phylogenetic and probably also functional impositions.—*H. F. Nachtrieb.*

2213. **FAVILLI, N. Il musculo diaframma nei ruminanti domestici. [The muscles of the diaphragm in domestic ruminants.]** 27p. Orsolini-Prosperi Tip.: Pisa, 1928.

2214. **JACOBSHAGEN, E. Zur Kenntnis und Charakterisierung des Rumpfdarmbaues der Lungenfische.** *Jahrb. Morph. u. Mikrosk. Anat. Abt. 1. Gegenbaur's Morph. Jahrb.* 63(2): 292-313. 3 fig. 1929.—The author considers the observations made by various investigators on Dipnoi, Amphibia, Selachii, Myxinoids and Petromyzontes. He found that in the Dipnoi the arteria and vena intestinalis dorsalis and ventralis spread within the tunica intermuscularis of the "spiral gut." The circulatory area of the arteria and vena intra-intestinalis lies predominantly in the tela submucosa. In the gut wall of *Protopterus* the veins of the tunica intermuscularis and of the tela submucosa anastomose through many delicate veins in the inner circular musculature. In the gut wall of *Protopterus* an intra-epithelial capillary network was also discovered lying in a plane below the middle of the epithelium. The meshes are elongated cranio-caudally. The capillaries are in delicate tubes of a colloidal tissue placed at regular intervals and are connected with the connective tissue of the basal membrane. The lymphoid organ is connected with the

outer walls of the blood vessels. The author thinks of it as an organ of the walls of the capillaries and veins. It is found in other vertebrates. In *Petromyzon* and *Ceratodus* it arises ontogenetically as a lymphoid organ of the vena subintestinalis. The conclusion is reached that the "trunk-gut" of the Dipnoi shows a close relationship to that of the selachians but not to that of the amphibians. Of course not all the relations can be given phylogenetic significance. A sharper distinction must be made between the analogous and the homologous, which will not only make clearer the phylogenetic position of the Dipnoi but will also explain the dynamic construction of the gut of the lung-fishes.—*H. F. Nachtrieb.*

2216. **TRETJAKOFF, D. Die schleimknorpeligen Bestandteile im Kopfskelett von Ammocoetes.** *Zeitschr. Wiss. Zool.* 133(3/4): 470-516. 9 fig. 1929.—The author deals with the following topics as related to cyclostomes: (1) their phylogenetic origin; (2) the mucoid cartilages; (3) the head muscles and their innervation; (4) bone and teeth; (5) the rostral portion of the head; (6) the hypophysis. The objective of the paper is the determination of the phylogenetic position of the lamprey and related forms. The conclusion is reached that the so-called mucoid cartilage (Schleimknorpel) is not a form of cartilage but a degenerate variety of reticular tissue and that it is not transformed into hyalin cartilage in the adult, which arises de novo from the blastema outside of the mucoid tissue. The head muscles of ammocoetes are derived from 2 sources, namely, from the anterior end of the parietal region and from the visceral region. From the former the M. supraocularis and M. subocularis arise and are innervated by the 2nd spino-occipital nerve, while from the latter 10 muscles are derived, all innervated by branches of the trigeminal nerve. The section on bone and teeth is largely a discussion of the observations of Stensiö, the author, and others on the bone structures in cephalaspids and related forms. There is no trace of bone structure in the lamprey larva or adult. The conclusion is reached that the cartilaginous skeleton of the rostral portion of the head of the lamprey is composed of specifically differentiated portions of the premandibular visceral arches 1 and 3. It seems probable that the unpaired cartilages apicalis and copularis and the paired spinosa and supra-apicalis and the mucoid structures have no phylogenetic significance but are new acquisitions which have appeared in connection with the sucking activities of the animal. The parolfactory gland of the lamprey, in addition to the parietal organ, is an example of the hormonization of an organ which originally functioned as a sense organ. The hypophysis of the ammocoetes is undoubtedly an endocrine organ but between the follicular cells there are spindleshaped cells which may be sense cells. It appears probable that the hypophysis originally was a taste organ. Recent researches on Ostracoderms and their supposed relations to cyclostomes are discussed.—*From abstr. by H. F. Nachtrieb.*

2217. **ABE, TATSUNDO. Ueber die schilfblattartigen Zellen.** [In Japanese.] *Shinkei Zasshi* 27(8): 1927.—These cells are a new kind of nerve cell which appear like reed leaves with toluidin blue stain. They appear larger with Bielschowski's stain and one can see lines of fibrils coursing in them. In man, one finds the cells in a particular zone in the rhinencephalon. They occur in ape, rabbit, dog, *Gorilla* and *Anthropopithecus*. The "reed-leaf-shaped" cells occur, in man as well as in the animals named, among the normal pyramidal cells in Brodmann's 5th zone. Average size of the cells in the toluidin blue stain is length 50-80μ, breadth 6-10μ; in the Bielschowsky stain, length 50-120μ, breadth 6-15μ. In man, the cells appear to become longer and to stain more deeply with age. The cells are believed on the one hand to be related to the perception of smell and on the other to have a motor function.—*O. Mori* (*courtesy Japanese Jour. Zool.*) (*transl. by H. A. Davenport*).

Sperim.* 5(5): 619-622. 1930.—The nerve fibers of the centrum ovale differ widely in size and shape; they show constantly the Schmidt-Lantermann's incisions. A slender sheath surrounds the fibers. Collaterals were not observed.—*M. Comel.*

2219. **BOEKE, J. Some remarks on the papers by H. J. Wilkinson on the innervation of striped-muscle fibers.** *Jour. Comp. Neurol.* 51(2): 299-309. 4 fig. 1930.—The periterminal network, described by the author in motor endplates and sensory corpuscles, is not an artefact due to prolonged fixation in formol, as is supposed by Wilkinson, but a real protoplasmic structure. It has been described by a number of authors, and not only by Boeke, as is maintained by Wilkinson, and it is found not only after fixation in formol, but with other methods too—even in living tissue. The description given by Wilkinson of preparations made by the author concerning the sympathetic innervation of striped-muscle fibers is erroneous and not according to facts.—*Author* (*courtesy Wistar Bibl. Serv.*).

Neurol., Psichiatr. e Psicoanal.* 11(1): 102-117. 2 fig. 1930.—Study of newborn infants and dogs indicated that the lymphatic capillary rate of the peripheral nerves originates from a closed system, not in connection with the interlamellary spaces of the perineurium which acts as a barrier. The efferent epineural lymphatic vessels after a brief course debouch into deep lymphatic vessels. No very long efferent collectors follow the course of the epineurium.

2223. **DURWARD, ARCHIBALD. The cell masses in the forebrain of Sphenodon punctatum.** *Jour. Anat.* 65 (1): 8-44. 22 fig. 1930.—The cerebral cortex is composed of 3 clearly definable sheets, a medial hippocampal cortex, a lateral pyriform cortex, and between these the general cortex. A densely staining clump of cells as a rule forms the lateral boundary of the general cortex. The pyriform cortex presents laterally a flattened area of marked constancy but of obscure causation. The relationship of pyriform cortex laterally to the hypopallium varies; caudally the 2 sheets meet at the angulus dorso-lateralis while rostrally the pyriform cortex lies superficially in the brain wall and is separated from the ependyma by the meeting of the general cortex and the hypopallium. The brain wall shows some increase in thickness where the general cortex and the hypopallium meet. The septum shows, in its pre-foraminal part, 2 distinct nuclear masses which have been termed nucleus septi medialis (which is also ventral) and nucleus septi lateralis (also dorsal). The lateral nucleus does not extend as far rostrally as the medial and is composed of distinctly large cells. The sulcus septostriaticus is said to lie not opposite the interval between the septum dorsally and the olfacto-striatum ventrally, but rather opposite the medial small-celled septal nucleus. Caudally in the septum other specialized masses are described, viz., the nucleus of the diagonal band and the nucleus of the posterior pallial commissure. The ventro-lateral segment of the hemisphere in *Sphenodon*

is not at all similar in the appearance of its cell masses to such forms as the alligator and the turtle. The hypopallium is divisible into anterior and posterior parts, the former meeting the general cortex laterally and the latter the pyriform cortex. There is no sharp line of demarcation between these 2 components of the hypopallium within the cell mass itself, but towards the poles of the hemisphere they present quite different appearances due to dissimilar cell grouping. The somatic striatum and olfacto-striatum are related to the lateral and medial forebrain bundles respectively. Their distinction in cell preparations depends almost entirely on differences in cell grouping, variations in cell size being of little assistance. A palaeostriatal cortex has been described consisting of those nuclear masses which are arranged about the ventro-lateral aspect of the palaeostriatum as a cortical covering; the tuberculum olfactorium and the nucleus of the lateral olfactory tract are the chief masses so related, though towards the caudal pole of the hemisphere the nucleus of the diagonal band and the amygdaloid nuclei have a somewhat similar relationship to the palaeostriatum. Two habenular nuclei are described and named rostral and caudal. These appear without any doubt to correspond to the medial and lateral nuclei of other forms, but the author can detect no evidence of a medio-lateral relationship between them. The majority of cell masses in the thalamus and hypothalamus are well-defined, circumscribed masses. —*From author's summary.*

2227. **HUBER, G. CARL, and ELIZABETH C. CROSBY. The nuclei and fiber paths of the avian diencephalon, with consideration of telencephalic and certain mesencephalic centers and connections.** *Jour. Comp. Neurol.* 48(1): 1-225. 19 pl. 1929.—This investigation is based on a study of 45 series of avian brains including cross and sagittal series of the brains of sparrow, dove, chicken, duck, and parrakeet, supplemented by certain frontal series. The fiber paths were studied in both $AgNO_3$ and Weigert preparations. The cell material was stained in toluidin blue following the special mercury-trichloracetic-alcohol fixative of Huber. The olfactory bulbs, while developed typically in duck, chicken and dove, are very small and somewhat atypical in layer arrangement in the parrakeet and are represented by a single very small bulb in the sparrow. The basal centers of the ventromedial forebrain wall are divisible into the prepyriform area of Rose, the nucleus olfactorius anterior, the nucleus accumbens and the septal or parolfactory area, which throughout part of its extent may be subdivided into secondary nuclei. All of these centers are poorly developed in comparison with the corresponding areas in reptiles and mammals, although the degree of difference varies with the bird considered, the centers being larger in those avian forms having more highly developed olfactory systems. The basal centers of the lateral forebrain wall reach a very high degree of development in the birds studied. The striatal portions (aside from the amygdaloid complex) are divided into a paleostriatum, an ektostriatum, a neostriatum, a hyperstriatum, a nucleus intercalatus hyperstriati, and a hyperstriatum accessorium, and several of these may be subdivided further. These divisions extend in broad bands across the hemisphere wall, overlying each other from the ventral to near the dorsal surface in the order named. The amygdaloid complex, as represented in the archistriatum, is situated in the caudal, basal part of the hemisphere, is quite well developed, and has associated with it a nucleus taeniae. Nucleus basalis is a secondary olfactory center (and also indirectly a trigeminal center) lying in close approximation to the paleostriatal and neostriatal areas. The cortical areas are, on the whole, relatively poorly developed in the forms studied, particularly in the parrakeet and the sparrow. They are represented in the sparrow by a small hippocampal region (pars dorsomedialis hippocampi of reptiles), the entorhinal area of Rose (pars dorsalis hippocampi of reptiles), an area adjacent to this latter termed the area paraentorhinalis, and a thin corticoid layer thickened somewhat in various regions into true cortex, which occupies the more superficial portions of the dorsal and dorsolateral hemisphere walls and, at various levels, is in intimate relation with the underlying hyperstriatal areas. A differentiated telencephalic periventricular gray borders a part of the ventricular wall. The preoptic area shows the usual relations. The diencephalic regions consist of the typical epithalamic, thalamic, and hypothalamic centers. The epithalamus is small in the birds studied, particularly in the sparrow and parrakeet. Thirty-odd thalamic nuclei were identified, among which may be mentioned the nucleus dorsomedialis anterior, the nucleus dorsolateralis anterior, the nucleus dorsolateralis posterior, the nucleus rotundus, the nucleus postrotundus, the nucleus subrotundus, the nucleus ovoidalis, the nucleus intercalatus, the lateral geniculate nucleus and the nucleus tractus habenulo-peduncularis. The hypothalamus also falls into a relatively large number of nuclear groups, comparable in part to those found in mammals. Tectal and certain pretectal and subtectal centers are prominent, among which are the pretectal, subpretectal, and spiriform nuclei, the nucleus mesencephalicus lateralis pars dorsalis (inferior colliculus), and the nucleus isthmi, including its several subdivisions. The fiber connections of the regions are described in great detail. Very small olfactory tracts connect the olfactory bulb with the nucleus olfactorius anterior, the prepyriform area, and the nucleus basalis and swing caudalward as small fascicles into the tractus fronto-archistriaticus et neostriaticus. Secondary connections for the ventromedial hemisphere wall with the hippocampus are provided through the septo-cortical and cortico-septal tracts, with the amygdaloid complex through the ramus basalis frontalis of the septo-mesencephalic system and with the hypothalamus and more caudal centers through the medial forebrain bundle. The nucleus basalis discharges through the tractus fronto-archistriaticus et neostriaticus, which bundle carries in addition a small number of lateral olfactory tract fibers and interconnections between the frontal portions of the neostriatum and the archistriatal and neostriatal regions in the caudal part of the hemisphere. The striatal regions are in relation with diencephalic and certain mesencephalic centers through the highly developed lateral forebrain bundle. The typical dorsal and ventral peduncles of this bundle, with their various subdivisions, are evident. The quintofrontal tract of Wallenberg, a partly crossed bundle from the chief sensory nucleus of the trigeminal to the lateral basal regions of the hemisphere, is demonstrable in the series. A well developed system of association bundles interconnects the various striatal areas. The components of the anterior commissure are well developed and the tractus occipito-mesencephalicus et bulbaris from the archistriatum and the caudal part of the neostriatum can be followed to the mesencephalon and bulb. A pallial commissure connects the cortical regions of the medial and dorsomedial hemisphere wall and the so-called septo-mesencephalic tract with its 3 major subdivisions—to the amygdaloid complex (ramus basalis frontalis), to the dorsal part of the diencephalon and tectum (ramus basalis dorsalis), and to hypothalamic and mesencephalic regions (ramus basalis caudalis)—is present. It is considered a part of the fornix longus system. Also from the basal part of the hemisphere the tractus infundibuli can be followed to its crossing in the retro-infundibular decussation. The various components of the stria medullaris were identified, particularly in the dove, and in the latter bird the very well

developed habenulo-peduncular system was plotted and described. The paper contains an account of the highly developed optic and the well developed supraoptic systems and discusses the numerous tecto-thalamic and thalamo-tectal tracts which interconnect the dorsal thalamic centers with the pretectal and tectal areas. Other tectal connections—such as the tecto-bulbar systems, the tecto-pretectal bundles, the posterior commissure and the isthmo-tectal tracts—were considered. A review of the ascending pathways from bulbar centers is included. In addition to these major fiber groups there are descriptions of many less prominent connections. A table of the various nuclear groups with their fiber connections summarizes the results. The communication closes with a brief discussion of certain neurological problems.—*Huber and Crosby.*

2228. **SANDERS, ESTHER BLICK. A consideration of certain bulbar, midbrain, and cerebellar centers and fiber tracts in birds.** *Jour. Comp. Neurol.* 49(1): 155-222. 14 fig. 1929.—The observations are based on the same series employed in the study of the avian diencephalon by Huber and Crosby ('29; see preceding entry). The eye muscle nuclei in birds are large and well differentiated. The oculomotor nuclear group is subdivided into a dorsolateral, a dorsomedial, a ventromedial and an accessory nucleus. Root fibers arise from all these nuclei, homolateral from most of them but contralateral, and perhaps homolateral as well, from the ventromedial nucleus. The cephalic end of the trochlear nucleus is not clearly delimitable from the dorsolateral oculomotor nucleus. Its root fibers follow the usual course. The abducens nuclear group consists of a major nucleus and a more ventral accessory nucleus, as described by Terni and others. The secondary connections of the eye muscle nuclei are rich and varied. Fibers connect the oculomotor nuclei with the nucleus mesencephalicus lateralis pars dorsalis, the pretectal and subpretectal nuclei, and the optic tectum. The nucleus isthmo-opticus sends fibers particularly to the accessory oculomotor (Edinger-Westphal) nucleus. Tectal fibers enter the dorsal surface of the trochlear nucleus. A fiber bundle connects the nucleus ectomamillaris and the oculomotor centers. The dorsolateral and dorsomedial oculomotor centers receive posterior commissure fibers. The medial longitudinal fasciculus interconnects the eye muscle nuclei and these nuclei receive (partly after decussation) fibers of the cerebello-motorius system. A superior olivary peduncle can be traced to the abducens nucleus. A chief sensory nucleus, a nucleus of the descending root, a nucleus of the mesencephalic root, and 2 motor nuclei—a dorsal and a ventral—represent the centers of the trigeminal nerve. Contralateral and homolateral trigeminomesencephalic tracts connect the first 2 centers with the tectum and crossed and uncrossed trigeminocerebellar paths relate them to the cerebellum, while internuclear fibers put them into synaptic relation with adjoining motor centers. The chief sensory nucleus gives rise to the quinto-frontal tract. The motor trigeminal centers receive cerebello-motorius fibers. The visceral sensory area at the place of entrance of the facial visceral sensory root consists of a very inconspicuous nuclear mass medial and slightly dorsal to the abducens nucleus. Two motor nuclei of the facial—a dorsal and a ventral—are present in the sparrow. The vestibular centers, which are particularly highly developed in birds, are represented by a large dorsolateral vestibular nucleus, subdivisible into smaller groups and regarded as representing an increase in the efferent vestibular centers in these forms, by an inferior and a superior vestibular nucleus, comparable to the similarly named mammalian vestibular centers, by a dorsomedial vestibular center, probably representative of the medial vestibular nucleus of mammals, and by a nucleus tangentialis. All of the centers receive vestibular root fibers. Internuclear fibers connect the tangential nucleus with the ventrolateral vestibular nucleus and with the vestibular centers of the opposite side and similar fibers pass from the ventrolateral to the dorsolateral vestibular nucleus and to the cerebellum. The superior vestibular nucleus is connected with the cerebellar nuclei. Emphasis is placed on the peculiar relations of certain neurons of the dorsolateral vestibular nucleus which are so oriented that their dendrites are in relation on the one side with afferent cerebellar tracts and vestibular root fibers and on the other side with efferent cerebellar tracts. The ventromedial vestibular nucleus—and possibly the dorsolateral as well (through the cerebello-motorius system)—sends fibers to the medial longitudinal fasciculus. The cochlear nuclei consist of a nucleus angularis, a nucleus magnocellularis, and a nucleus laminaris, all of which receive cochlear root fibers. A superior olivary nucleus is present. The secondary connections agree with those generally given for reptiles and birds, consisting largely of bundles which cross as arcuate fibers to enter the lateral lemniscus. A peduncle of the superior olivary nucleus and a cochleo-cerebellar tract are described. With the small development of gustatory sensibility in birds, the glossopharyngeal portion of the fasciculus solitarius is small. A dorsal visceral sensory area receiving root fibers of this and the vagus nerve is demonstrable at their level of entrance; between the hypoglossal nucleus and the dorsal efferent nucleus of the vagus a ventromedial visceral sensory area is present. Many root fibers of these nerves, particularly of the vagus, swing caudalward, forming a large postvagal portion of the fasciculus solitarius, concerned presumably with carrying general visceral sensibility. The dorsal efferent nucleus of the vagus is divisible in the sparrow into 3 nuclear groups, each with special cytologic characters. A ventral motor nucleus of the vagus is present. The author believes that part of the motor fibers of this nerve arise from the nucleus intermedius, which is thought to give rise, also, to root fibers of the hypoglossal. The ventral hypoglossal nucleus is figured and reticular nuclei, comparable to those found in certain other higher vertebrates, are described. A well developed inferior olivary nucleus is present. The paper also contains an account of the cerebellar nuclei (following the terminology of Cajal) and a résumé of the main cerebellar connections. —*Huber and Crosby.*

2229. **JANSEN, J. Contribution to the innervation of the diaphragm of the goat.** Dissertation, University of Utrecht: Utrecht, 1930.—The diaphragm of the goat is innervated exclusively by the Nn. phrenici (C_5 and C_6). The sympathetic innervation takes origin from the cervical sympathetic (ganglion colli superius, ganglion stellatum). When the sympathetic nerves are cut through on 1 side, the diaphragm on that side partly loses its tonus. Sixty-five days after the section of the sympathetic nerves, the author could find no appreciable changes in the microscopic structure of the muscle fibers of the diaphragm.—*J. W. Langelaan.*

2230. **KADANOFF, DIMITRI. Über die Nerven in der äusseren Wurzelscheide der Haare des Menschen.** *Zeitschr. Wiss. Biol. Abt. B. Zeitschr. Zellforsch. u. Mikrosk. Anat.* 6(5): 631-636. 2 fig. 1928.—Nerve endings inside of the membrana vitrea of the hair follicles of lips, chin, and eyelids (cilia) of man are described. They are not found in all, but only on the larger follicles and are fewer in man than in other mammals. Among the cells of the outer root sheath the fibers either form touch-discs, i.e., fine, sickle-shaped, fibrillar nets, or terminate in free endings. The touch-discs are fewer and much smaller than those of the sinus hairs of animals. A single nerve fiber forms several which lie at different levels in the sheath adjacent to touch cells of Merkle, i.e., clear oval ones which, so numerous in other mammals, are scarce in man. Whether the free endings and the touch-discs belong to independent nerve fibers is not known.—*W. F. Windle.*

2232. **KOLDA, J. Příspěvek k anatomii břišního sympatiku u koně. [The abdominal sympathetic nervous system of the horse.]** *Biol. Spisy Vysoké Školy Zvěrolé-*

kařské Brno (*Publ. Biol. École Vétérinaires*) 6: (153)-(239). 5 pl., 9 fig. 1927.—Fourteen specimens were studied; in at least 10 cases every structure was prepared on both sides. The lumbar part of the sympathetic trunk of the horse is characterized by an irregular distribution of the ganglionic tissue, after the branching off of the thoracic and lumbar splanchnic nerves, i.e., at the level of the 18th thoracic and 1st lumbar vertebrae, and the 4th and 5th lumbar vertebrae, there is little ganglionic tissue, irregularly distributed in greater or smaller isles. Relatively very little ganglionic tissue is to be found where the posterior branches of the lumbar splanchnic nerve are given off, i.e., at the level of the 2nd and 3rd lumbar vertebrae and in the sacral region at the end of the 5th and at the level of the 6th lumbar vertebrae; in these parts the sympathetic trunk is penetrated by a broad and often coherent ganglionic mass. In horses it was possible to distinguish on new preparations the rami communicantes albi et grisei. While the gray rami communicantes lead to every lumbar spinal nerve, the white ones may be observed macroscopically up to and including the 4th lumbar spinal nerve, whereas the 5th and 6th have only gray rami communicantes. The gray branches, as in the thoracic region, are connected with the appropriate segmental ganglia. The white branches enter the sympathetic trunk in the central part of the thorax close to the ganglia; at the level of the last thoracic vertebra and especially at the level of the first 2 or 3 lumbar vertebrae each white ramus entering the sympathetic trunk runs posteriorly to the level of the following segmental spinal ganglion. The gray rami extend from the dorsal surface of the sympathetic trunk or from its median margin; the white enter the lateral margin. Their superficial bundle often can be traced directly over the sympathetic trunk into its peripheral branches and particularly into the lumbar splanchnics. The peripheral branches of the sympathetic trunk, which enter the abdominal ganglia, are the thoracic and lumbar splanchnic nerves. Of the former, the largest is the greater splanchnic nerve, which arises with its 1st root from the 6th, 7th or 8th thoracic ganglion and receives further branches from the other ganglia except the 2 or 3 last. It enters the semilunar ganglion of the respective side. The 1st lesser splanchnic nerve is the last independent branch from the 15th to 17th thoracic ganglia to the greater splanchnic nerve. The 2nd lesser splanchnic nerve has an independent course, extends posteriorly and also enters into the semilunar ganglion of the respective side. In 5 cases on the left and in 4 cases on the right side a direct branch of the 2nd lesser splanchnic nerve enters the renal plexus; in the other cases its superficial bundle was followed into the roots of the renal branches above the lateral brim of the semilunar ganglion. N. splanchnicus imus arises at the level of the last thoracic or 1st lumbar vertebra; on the left side it enters the 1st renali-aortic ganglion, and on the right side the semilunar ganglion, which there probably unites with the above mentioned ganglion. In the course of the Nn. splanchnicus maior, minor secundus et imus more or less well developed ganglia are present where they pierce the diaphragm: they are the ganglia nervi splanchnici. By histological methods the author has proved that these masses are not accessory adrenal glands. The characteristic position of these ganglia in the place where the nerves pierce the diaphragm justifies the following explanation of their origin. The ganglionic cells which wandered along the splanchnic nerve from the peripheral ganglia were stopped by the diaphragm and formed the ganglia nervi splanchnici. The lumbar splanchnic nerves show numerous variations. In general there are 3 on each side. The best developed on the right side is usually the 2nd, on the left side the 3rd. They adhere to the abdominal aorta and therefore run on the right side between the abdominal aorta and posterior abdominal vein. In the mare they are especially developed posteriorly. The 1st enters either the 2nd renali-aortic ganglion or the marginal collateral from the aortic plexus, not far from the above mentioned ganglion. It is generally the smallest. The 2nd enters partly the anterior spermatic ganglion and partly the median sperm. ganglion. The 3rd rarely enters the latter, more frequently it enters the branch connecting this ganglion and the posterior sperm. ganglion. The ventral trunk of the vagus innervates principally the stomach and sends only a small part of its filaments in the direction of celiac plexus. The dorsal trunk participates relatively little in the innervation of the stomach. The largest part of it enters the plexus solaris, whence it may be followed in the colic tract to the liver and to the arteries of the small intestine. Into the right semilunar ganglion always enter the stronger bundles of the vagus, while into the left semilunar ganglion weaker bundles could be traced sometimes. Plexuses, which enlace the branches of the celiac artery, are formed by nerves especially from the left semilunar ganglion. These nerves arise from the anterior enlargement of this ganglion; this enlargement is probably homologous to the celiac ganglion of man. Both ganglia participate equally in the innervation of the small intestine. The large intestine and the cecum receive their nerves mainly from the right semilunar ganglion. These branches centralize at first in a typical formation, the colic tract, consisting in horses of the following parts: The pars prima of the colic trunk, which runs from the posterior mesenteric ganglia along the posterior mesenteric vein, giving small branches to the small colon and passing into the genu tractus colici. Branches enter it principally from the right, in a lesser measure from the left semilunar ganglion, and also large branches of the vagus. From it extend nerves, forming the plexus on the A. colica dorsalis. Afterwards it passes into the pars transversa tractus colici, which receives further branches from the right semilunar ganglion. Nerves from it go into the plexus ileocaecocolicus, directly or with the aid of the ansa tractus colici; this encloses the ileocaecocolic vein and partly enters into the plexus of the small intestine. Into the adrenal gland come nerves from the ganglion of the great splanchnic nerve, from the lateral margin of the semilunar ganglion, from the ventral surface of this ganglion along the A. suprarenalis perforans and from the plexus of the kidney. Also, the direct branch of the 2nd lesser splanchnic nerve enters the kidney nerves, mainly from the lateral margin of the semilunar ganglion of the same side. These nerves form the plexus of the kidney, in which there are 1 or 2 ganglia, giving branches into the anterior and median parts of the kidney. The posterior parts receive their nerves from the 2nd renali-aortic ganglion. From this ganglion a branch always extends in the direction of the adrenal gland. In its course there is the caudal suprarenal ganglion from which small branches may be traced into the renal ganglion, the adrenal gland, the kidney, and the ureter. Usually the abdominal aortic plexus is formed by 3 collaterals. Both marginal collaterals extend from the 2nd renali-aortic ganglion of the same side, receiving the anterior lumbar splanchnic nerves and having an anterior spermatic ganglion on each side. The internal branch enters the posterior mesenteric ganglion and the external branch the median spermatic ganglion of the same side. The central collateral extends from the posterior margin of the interganglionic connection and enters mostly into the right marginal collateral. At the point of union of both collaterals is the median mesenteric ganglion. The 2 posterior mesenteric ganglia are more or less fused together. They send branches to the anterior hemorrhoidal artery, to the left colic artery and form the pars prima of the colic tract. The median spermatic ganglion receives the external branches from the marginal collaterals and a part of the posterior lumbar splanchnic nerves. The posterior spermatic ganglion receives the last lumbar splanchnic nerve, and this either directly or through the branch which connects it with the median spermatic ganglion. From the posterior spermatic ganglion extends the greatest part of the spermatic (resp. utero-ovarian) nerves and, in a posterior direction, one smaller and one larger hypogastric nerve. The position of the sympathetic trunk and the irregularly distributed ganglionic tissue in the lumbar region in horses

finds its homologue in animals and especially in man, where these conditions were particularly studied. The same is true for the white and gray rami communicantes. In the Anthropomorpha and Ungulata the great splanchnic nerve branches off very far anterior in the thorax; in the lowest mammals this nerve is not developed. Immediately posterior to the diaphragm, branches arise from the sympathetic trunk and lead into the solar ganglion. They are homologous to the thoracic splanchnic nerves of higher mammals. The development of thoracic splanchnic nerves is considered, therefore, as a sign of superior organization. Those mammals which have a greater splanchnic nerve have also, in a great majority of cases, the ganglion nervi splanchnici maioris. It is in a characteristic position near the diaphragm and sends branches to the adrenal gland as in horses. Careful research showed direct branches of the small splanchnic nerves into the renal plexus in some animals and man as in horses. The roots of the great splanchnic nerve in reality reach more anteriorly than can be proved by macroscopic dissection, but the posterior limit of the lumbar splanchnic nerve, as ascertained by dissection, is the same, or nearly the same, as that obtained by experimental methods. The final branching of the vagus, in horses, resembles in plan that in other animals and man. The ganglia of the solar plexus vary in number as well as in position. These variations are not dependent upon the kind of animal but appear in individuals of the same kind, especially in man. The abdominal aortic plexus (sensu latu) as described in man and anthropoid apes is similar to that in horses and rabbits with regard to number and position of its ganglia as well as with respect to its interganglionic and peripheral branches.—*Author's English summary.*

2233. **KOLESNIKOW, V. Die Wirkung der Desympathisierung von Arterien mit Alkohol nach Rasumowsky auf die Entwicklung von Kollateralen. (Anatomisch-experimentelle Untersuchung.)** *Vorläufige Mitteilung. Zeitschr. Ges. Anat. Abt. 1. Zeitschr. Anat. u. Entwicklungsgesch.* 89(4): 405-411. 1 fig. 1929.—The author reports 9 experiments on dogs in which he applied, à la Rasumowsky, 80% alcohol to the main artery of the foreleg after the distributing arteries had been variously occluded, and concludes that of the noted empirical methods of influencing the sympathetic nervous system in sympathectomy that of Rasumowsky is the most promising.—*H. F. Nachtrieb.*

2234. **KOLOSSOW, N. G., und G. W. SABUSSOW. Beiträge zum Studium der sympathischen und spinalen Ganglien einiger Reptilien und Vögel. Die Ganglien von Emys europaea L., Anser cinereus L. und Columba livia L.** *Jahrb. Morph. u. Mikrosk. Anat. Abt. 2. Zeitschr. Mikrosk. Anat. Forsch.* 18(1/2): 5-36. 21 fig. 1929.—The relationship of the ganglia of the sympathetic trunk to the spinal ganglia is considered and the ganglion cells in both the sympathetic and the spinal ganglia are described, particularly in regard to form, number and distribution of processes and internal structure. In the species studied, the cervical sympathetic ganglia are entirely distinct from the spinal ganglia, but the ganglia of the sympathetic trunk, throughout the thoracic and lumbar regions, are so intimately associated with the spinal ganglia that there is some intermingling of sympathetic and spinal ganglion cells. In the turtle, the majority of the sympathetic ganglion cells in the thoracic and lumbar segments are in general pyriform, having a heavy cone-shaped extension from which all the cell processes, usually not exceeding 3 or 4, arise. In some instances 1 or more processes, in addition to those arising from the cone, arise directly from the cell body. The neurofibrillar apparatus exhibits a perinuclear or central and a peripheral plexus. The latter lies somewhat beneath the surface of the cell body, leaving a relatively clear peripheral zone. No anastomosis of neurofibrils was seen. Chondriosomes are present throughout the cytoplasm, but are more abundant in the perinuclear zone than at the periphery. The cervical sympathetic ganglia in the turtle contain ganglion cells of 2 distinct types, viz., (1) cells with a broad oval cell body from 1 side of which several processes arise. These cells have no cone-shaped extension. The neurofibrils in the perinuclear plexus are relatively coarse; those in the peripheral plexus much finer; (2) cells with a rounded cell body and a definite cone-shaped extension. The perinuclear fibrillar plexus is well developed in these cells, but they exhibit no peripheral fibrillar plexus. The spinal ganglion cells in the turtle are essentially unipolar, but some show protoplasmic outgrowths (not regarded as dendrites), some of which extend as far as the wall of the ganglion cell capsule. The spinal ganglion cells contain a relatively heavy neurofibrillar plexus distributed more or less uniformly throughout the cytoplasm. Cells, in form and structure intermediate between spinal and sympathetic ganglion cells, occur in small numbers in the spinal ganglia. Chondriosomes are present throughout the cell body. The sympathetic ganglion cells in the birds studied are essentially multipolar, but the number of processes is relatively small. The neurofibrils are well developed and are rather uniformly distributed throughout the cytoplasm. Those at the periphery are in general finer than those in the deeper parts of the cell body. Chondriosomes are present throughout the cell body. The spinal ganglion cells in birds conform to the usual unipolar type.—*A. Kuntz.*

2235. **KUHLENBECK, HARTWIG. Bemerkungen über den Zwischenhirnbauplan bei Säugetieren, insbesondere beim Menschen.** *Anat. Anz.* 70(6/7): 122-142. 14 fig. 1930.—The sulcus hypothalamicus of Monro of mammals is homologous with the sulcus diencephalicus ventralis of anamniotes. The pars ventralis thalami of anamniotes must therefore correspond in mammals to a part of the actual thalamus dorsal to the sulcus of Monro. Dorsal to that sulcus there exists in mammalian fetuses a groove which, in view of its prominence, presents a very variable relation. It may appear as a hardly significant depression, as a deep sulcus, or as a groove with an overlying ridge (as a double furrow). According to its position in the structural plan, this furrow corresponds absolutely to the sulcus diencephalicus medius of anamniotes. The sulcus diencephalicus medius can be seen even in fully developed human brains in case the massa intermedia is not present. It is claimed that the nucleus dorsalis or anterior and the nucleus medialis belong to the pars dorsalis thalami in man, and the nucleus ventralis and lateralis to the pars ventralis thalami. The relations of a number of the nuclei to these basic divisions are questionable and need further explanation. The structural plan of the human or mammalian 'tweenbrain (diencephalon) is identical with that of the anamniotes. The same connections appear in the 4 zones of Herrick, conceived as basic constituent parts.—*Author's summary (transl. by J. M. Nielsen).*

2236. **KURÉ, KEN, YOSHIO NITTA, MORIMASA TSUJI, KENSAKU SHIRAISHI, und BINJI SUENAGA. Die histologische Darstellung der parasympathischen Fasern in den hinteren Rückenmarkswurzeln der Lumbalsegmente.** *Pflüger's Arch. Ges. Physiol.* 218(5/6): 573-585. 4 fig. 1928.—In 2 dogs the posterior roots of the 5th, 6th and 7th lumbar and the 1st and 2nd sacral nerves were severed on one side and the spinal ganglia on the other side. Both sides were atrophied 87 and 95 days respectively after the operation, but the side on which the spinal ganglia were extirpated was more wasted, indicating that after section of the nerve roots the spinal ganglia continue to transmit trophic impulses, and also that, if parasympathetic fibers are really present, they must have in the spinal ganglia a ganglionic center capable of sending out a certain independent impulse after the fibers above the spinal ganglion are severed. Histologic study of the peripheral end of the posterior root of the 7th lumbar nerve in one dog and of the 6th nerve in another (cut in both cases above [central] from the spinal ganglion) showed degeneration of the thick myelinated fibers (with corresponding degeneration and chromatolysis of certain cells in the spinal cord between anterior horn and substantia gelatinosa) while

the thin myelinated fibers were unchanged; hence the fibers appear to be spinal efferent or parasympathetic fibers. Apparently the vasodilatation produced by stimulation of the posterior roots is effected by the trophic and tonic influence of these roots on the voluntary musculature.

Anat. e Embriol.* 28(2): 238-252. 1930.—Examinations of sections perpendicular and tangential to the convolutions of the cerebellar cortex of pigs, calves, lambs, and cats, and stained by the methods of Golgi, Cajal and Bielschowsky, show that in the stratum granulosum there is a rete nervosum diffusum as defined by Golgi, which morphologically is not confined to this stratum but presents important connections with the systems of nerve fibers which extend into the molecular stratum through its lower third. In the rete an interlaced complex system of fibers of comparatively large size (1st order) may be distinguished from a rather delicate system of fibrillae (2nd order). Extensive and important communications can be shown between the 1st order system of the rete, the sub- and superganglionic plexuses of Cajal and the pericellular baskets. There are also connections between the rete granulosum, the sub- and superganglionic plexuses, and the baskets by means of a mesh of fibrillae; the baskets are also interconnected by fibers and fibrillae and therefore cannot be regarded solely as terminal formations but are also one of the principal elements of nervous connection between the stratum granulosum and the stratum moleculare. The baskets appear as so-called "terminal brushes" only because incompletely stained or because in the sections they have been cut obliquely.—*Summary (transl.).*

2242. **MOSKOFF, M. Plexus brachialis при домашнитѣ птици.** [P. brachialis in domestic birds.] Годишникъ на Софийския университетъ, Ветеринарно медицински факултетъ (*Jahresber. Univ. Sofia, Vet. Med. Fakultät*) 5: 299-317. 8 fig. 1929.—The brachial plexus of domestic birds is formed of the ventral branches of the following spinal nerves: 13, 14, 15, 16, 17 in chicken; 14, 15, 16, 17 in turkey; 15, 16, 17, 18 in duck; 17, 18, 19, 20 in goose. Thus the sequence of the nerves forming the plexus depends upon length of neck. Formation of the plexus, especially in the goose, occurs rather far away from the vertebral column.—*A. Kalojanoff (transl. by E. W. Count).*

2243. **MUSSGNUG, HANS. Der Anteil des N. phrenicus an der Innervation von Brust- und Bauchorganen beim Hunde.** *Deutsche Zeitschr. Chir.* 227(1/6): 132-144. 1930.—Anastomoses between the phrenic and sympathetic nerves of the dog were described. In 16 dogs the physiological action of the phrenic on the thoracic organs and stomach was examined. This nerve has no effect on the heart but the blood pressure is raised by stimulation of the central end of the severed phrenic (sensory reaction). The tone of the bronchial musculature is not influenced by it. The chief effect on respiration of central stimulation of the severed phrenic nerve is to decrease its rate. The influence of the phrenic on the oesophagus in the presence of phrenic-sympathetic anastomoses was demonstrated experimentally; and the phrenic was found, in this case, to contain motor and sensory fibers to the oesophagus. In the absence of these anastomoses an influence of the phrenic on the oesophagus is not found. One experiment demonstrated the participation of the sympathetic in the innervation of the oesophagus. Stimulation of the peripheral stump of the phrenic caused contractions of the pyloric region of the stomach. —*Summary (transl. by O. W. Tiegs).*

2244. **PAPILIAN, VICTOR, et VASILE DAGHIE. Les nerfs cardiaques thoraciques sous-stellaires.** *Compt. Rend. Soc. Biol.* 98(1): 61. 1928.—A very brief description of newly discovered branches from the inferior cardiac branches in man.

2245. **PETRONIEVICH, BRANISLAV. Kratak pogled na istoriiski razvitak noviie uporedne anatomiie ostrva na sisarskom mozgu.** [Historical note on the new comparative anatomy of the insula of mammals.] [French summary.] *Srpska K. Akad., Prirodnachki i Matematichki Spisi,* Book 20. pp. 1-79. 11 pl. 1930.—Literature on the island of Reil is reviewed historically and critically, and the development of the knowledge of this region is traced.

2246. **PING, C. On the cerebrum of Felis tigris.** *Proc. Zool. Soc. London* 1930(1): 147-159. 13 fig. 1930.—The specimen was from an adult Bengal tiger 182 cm. in body-length. The brain weighed 282.4 gm. and its volume was 254 cc. It was hard even in the fresh condition. The principal structures were more complicated than in the cat's brain. The gyri were indented with short branches of the principal sulci or with small sulci. The lateral sulci were comparatively complicated. The dorsal aspect of the cerebrum looked asymmetrical due to minor variations of the sulci. Most of the sulci were rather wide, especially the great longitudinal fissure. The diagonal fissure was different from those recorded for Felidae. Almost parallel to the olfactory tract and close to the ventral margin of the frontal lobe was a short sulcus, provisionally named "sulcus rostralis." The fissura sublimica of Kukenthal was poorly developed on the medial surface. Some internal structures, which are not conspicuous in the cat's brain, such as nucleus caudatus, capsula interna, putamen and globus pallidus of the nucleus lentiformis, and the involution of the hippocampus into the inferior horn of the lateral ventricle, were definite and significant. The region of the frontal lobe anterior to the cruciate sulcus was steeper than that of *Canis familaris.* The large motor cells in the cortex of the frontal area were conspicuous.—*C. Ping.*

2247. **RIJNBERK, G. van, et L. KAISER. Segmentation métamérique et innervation radiculaire spinale des muscles de la paroi abdominale chez le chien. Recherches expérimentales. 1ère partie: Introduction et muscle droit de l'abdomen.** *Arch. Néerland. Sci. Exactes*

et Nat. Sér. 3 C 14(1): 71-136. 106 fig. 1929.—The attachments and nerve supply of the muscle are given. The muscle is described as composed of a cranial non-segmented part, a middle portion comprising 6 tendinous inscriptions which limit 5 muscular segments, and a caudal portion incompletely divided into 2 parts by a 7th rudimentary inscription. The experimental method used was principally the electro-stimulation of the spinal nerve roots and their peripheral rami innervating the rectus muscle. Observations were made by the naked eye, by photography, by measurement and by graphs. From experimental study of 38 dogs, the authors found: the cranial non-subdivided part was innervated generally by the 4th-6th thoracic nerves; the middle part by the 7th, 9th, 10th, 11th and 13th thoracic nerves, supplying in consecutive cranio-caudal order its 5 segments, while the 8th was distributed to the 1st or 2nd segment or both and the 12th thoracic innervated the 4th or 5th segment or both; the caudal portion was innervated by the 1st and 2nd lumbar nerves, each peripheral nerve had motor branches from but 1 ventral spinal root; even though a segment was supplied by 2 nerves, each of the individual muscle fibers was innervated by but 1 root.—*H. L. Foust.*

2248. RILEY, HENRY ALSOP. The lobules of the mammalian cerebellum and cerebellar nomenclature. *Arch. Neurol. and Psychiatry* 24(2): 227-256. 24 fig. 1930.—A schematic classification is suggested embracing the constituents of the cerebellum and a group of terms applying to them is recommended for the use, not only of the human anatomist, but also of the comparative morphologist, the embryologist and the physiologist.

2249. SIMONETTA, BONO. Sulla presenza di un ganglio nervoso nel ramo linguale del glossofaringeo della pecora. Ricerche embriologiche e comparative sui gangli simpatici del glossofaringeo dell'uomo e di altri mammiferi. [Presence of a ganglion on the lingual branch of the glossopharyngeal nerve in sheep: embryologic and comparative studies of the sympathetic ganglia of the glossopharyngeus in man and other mammals.] *Arch. Ital. Anat. e Embriol.* 28(1): 1-21. 8 fig. 1930.—Studies of 8 sheep fetuses and a bovine fetus, compared with a series of white rat embryos and 2 human fetuses, led to the establishment in ruminants of a large, hitherto undescribed sympathetic ganglion in relation with the lingual branch of the glossopharyngeal; its cells belong to Cajal's Type I. The ganglion develops from cells which have migrated from the petrous ganglion along the trunk of the glossopharyngeal. It seems probable that this ganglion and the other small ganglia, more distal on the glossopharyngeal, produce a secretory action on the small salivary glands scattered over the mucosa of the base of the tongue and the pharynx.

2250. SLAVICH, ERVINO. Confronti fra la morfologia dei neuroni dei vari gangli simpatici e del parasimpatico encefalico. [Morphology of the sympathetic ganglia as compared with those of parasympathic.] *Boll. Soc. Ital. Biol. Sperim.* 5(3): 306-309. 1930.—Remarkable morphological differences were noted in the sympathetic ganglia as compared to the ciliary ganglion of ox and horse; their significance is under investigation.—*M. Comel.*

2252. SSINELNIKOW, R. Die Herznerven der Vögel. *Zeitschr. Ges. Anat. Abt. 1. Zeitschr. Anat. u. Entwicklungsgesch.* 86(5/6): 540-562. 11 fig. 1928.—The observations were made on 156 hearts of the crow, raven, daw, pigeon, chicken, duck and goose. The figures are drawn from preparations of the heart of the goose. The 6 nerve plexuses of the heart described with their location and the region innervated are:—plexus anterior cordis sinister, and dexter, and nerve ring of the bulbus aortae; plexus cardiacus posterior dexter, and sinister; plexus atriorum anterior, and posterior (Pl. sinus Halleri). Author's summary:—The avian heart is innervated by branches of the vagus and the sympathetic. The branches reach the heart along definite paths and at certain points exchange fibers or form special plexuses. Both the vagus and sympathetic are represented in the plexuses and all neighboring plexuses anastomose with each other either directly or indirectly. A region of ganglia is present either at the beginning or in the middle of the plexus. Each plexus and its corresponding field of ganglia are located at a particular region of the heart. Each field of ganglia receives a number of fibers from its plexus and sends out a number of fibers that unite into branchlets which have a definite topographical position and function. In the majority of cases the number of nerve fibers that enter the field of the ganglia is less than the numbers that go out from it.—*H. F. Nachtrieb.*

2253. SSINELNIKOW, R. Das intramurale Nervensystem des Vogelherzens. *Zeitschr. Ges. Anat. Abt. 1. Zeitschr. Anat. u. Entwicklungsgesch.* 86(5/6): 563-578. 5 figs. 1928.—(See also preceding entry.) The material consisted of 54 hearts of the pigeon, chicken, duck, goose and turkey. Author's summary:—The auriculoventricular septum of the bird's heart is innervated by the vagus and sympathetic branches that form the 6 extramural nerve plexuses of the heart. The anterior portions of the septum furthermore receive nerves from the ganglia of the nerve ring of the bulbus aortae. The posterior portions of the ventricular septum receive branches directly from the ganglia located on both sides of the sulcus longitudinalis post. The author distinguishes on each side of the partitions of the heart an intramural and an endocardial plexus which anastomose with each other and are derived from common as well as different sources. The plexuses of the septum are always formed by branches from the extramural plexuses and their locations are constant.—*H. F. Nachtrieb.*

2254. TOYOTA, SOSAKU. Beiträge zur Kenntniss der Anatomie des Plexus Tympanicus des Menschen. *Acta Scholae Med. Kioto* 11(1): 7-29. 1928.—The tympanic nerve and its related structures are described in detail from a study of 60 ears of new-born Japanese. The adjoining parts and the origin, course, anastomoses, branches and distribution of the nerve are discussed from an anatomical and biometrical standpoint. Newly named and unnamed connections unite the tympanic nerve with the carotid plexus and neighboring nerves. The ramuli anastomosis caroticopharyngei (in 31 out of 60 cases), connecting the carotid plexus with the pharyngeal ramus of the tympanic nerve, is named for the first time. The ramus caroticopharyngotympanicus (in 6 out of 60 ears) leaves the carotid plexus as 1 fiber and divides into 2 rami. One ramus goes to the pharyngeal branch of the tympanic and the other to the tympanic nerve. Unnamed anastomoses exist between the facial and tympanic nerve and rare branches occasionally unite the tympanic plexus with surrounding nerves.—*A. M. Lassek.*

2255. VEIT, OTTO. Zur Theorie der Entstehung der Nervenbahnen. Ein Versuch. *Anat. Anz.* 62(19/20): 373-378. 1926.—The histogenesis of the nerve fiber is so well worked out that perhaps only the question of the influence of the neurilemmal cell on the outgrowing fiber remains to be solved; however, the study of the origin of nerve tracts has only begun. A review of the literature suggests a working hypothesis as follows: (1) Franz ('23) found that in *Amphioxus* the dendrites and axones of the "giant cells" of the spinal cord run alternately to right and left so that the innervation of the motor ganglion cells on the 2 sides is alternate. He believes this is associated with the swimming motion. He also found that the infundibular tract is crossed anteriorly but uncrossed caudally. He sees a relation between this and the turning reflex when light strikes the animal. This suggests that in the nerve tracts form and function correspond to one another. (2) Burr ('16, '23) found that in *Amblystoma* the extirpation of the olfactory placode and the hemisphere of the same side results in a closing of the interventricular foramen of that side with ependymal

cells and that no regeneration occurs; that, however, removal of the telencephalon alone results in its regeneration as soon as the olfactory fibers grow out; and finally that grafting of a supernumerary placode results in the development of an accessory olfactory nucleus. Detwiler ('19, and later) found a similar relation in *Amblystoma* between the limb bud and the corresponding spinal ganglia. Transplantation to the other side leads to great increase of ganglion cells on that side. Afferent fibers grow first; motor fibers grow only after the descending psychomotor fibers reach their spinal cord level. These 2 pieces of work indicate that the development of sensory fibres is dependent upon the influence of stimuli from the periphery, that of motor fibers upon stimuli from the center. (3) Coghill ('13) found that the ventral nerve roots in *Amblystoma* grow out as collaterals of the descending axones of the motor ganglion cells. With increase of function of the myomere the collaterals become the main fibers. This means that development corresponds to use. (4) There is evidence that nerve impulses are specific, that sensory impulses differ qualitatively from motor, that end organs are also specific in the type of stimulus they can receive. This would account for processes of motor cells eventually attaining connection with muscle cells (all other processes of these cells would degenerate from lack of use). The interrelation of these concepts gives adequate foundation for a theory of the origin, distribution, and relative development of the nerve tracts.—*E. McCrady, Jr.*

2256. VOGEL, KLAUS. Die Beziehungen des Ganglion sphenopalatinum zu den von ihm ausgehenden Nervenstämmen. *Zeitschr. Hals-, Nasen- u. Ohrenheilk.* 25(5): 485-502. 18 fig. 1930.—The N. vidianus leaves the ganglion directly. The N. sphenopalatinus goes only a short way from the ganglion before it is divided into component fibers, some of which run anteriorly, and others laterally, to unite with fibers of the Nn. palatini. The N. palatinus major consists largely of fibers which come from the 2nd branch of the trigeminal, without being interrupted by the ganglion. Only a few fibers arise from the ganglion. About 10-12 nerve trunks pass to the nostrils. One of the largest, the N. nasopalatinus scarpae, supplies the nasal mucous membrane. All nasal nerves, which supply the upper part of the nostrils, the roof of the pharynx and the nasal mucosa, come from the sphenopalatine ganglion. The N. nasopalatinus contains fibers only from this ganglion. From the sphenopalatine ganglion many small nerves supply the fissura orbitalis inferior, and there anastomose with the 1st trigeminal branch. They form several small ganglia on the way to the orbital region. These contain no elements from the 2nd trigeminal branch.

2257. VOGT, MARTHE. Über fokale Besonderheiten der Area occipitalis im cytoarchitektonischen Bilde. *Jour. Psychol. u. Neurol.* 39(4/6): 506-510. 4 pl. 1929.—From a study of the area striata the author concludes that each histological area of the cortex is characterized by features whereby it can be identified but that in addition there are differences within: this whole area affecting thickness of a layer, size of cells, etc., scattered through it. These secondary differences, which have a constant extent and position, are not sufficient to obscure the identification of the area but perhaps are sufficient to afford a basis for diversity of function within that area.—*H. Woollard.*

2258. VOLKMANN, RUEDIGER von. Vergleichende Cytoarchitektonik der Regio occipitalis kleiner Nager und ihre Beziehungen zur Sehleistung. *Zeitschr. Ges. Anat. Abt. 1. Zeitschr. Anat. u. Entwicklungsgesch.* 85 (5/8): 561-657. 28 fig. 1928.—In the occipital regions of mouse, rat, dormouse and squirrel, the highest grade of differentiation was found in the squirrel, which coincidently also has the most highly developed optic function among the rodents. In mouse, rat, or dormouse the occipital region consists of 2 uniform fields, the area striata (17) and the area occipitalis (18), both of which are representatives of the 6 layered homotypic isocortex. In the squirrel the lamina IV of field 17 is subdivided into 3 layers as in man. This 3-fold striated cortical area is called "subarea eustriata." The author adopts the theory of Barany and Kleist, that the 3 layers of lamina IV indicate the anatomic representation of binocular vision. Its occurrence in the squirrel and not in the other rodents is coincident with the highly developed ability of this animal to estimate distances. This ability is made possible by stereoscopic vision. Following Kleist's theory the homonymous visual fields of both eyes are projected into the same hemisphere. The light sensation from the homolateral eye is projected into the upper layer of lamina IV, that from the opposite eye into the lower layer, IV c. Phylogenetically, the subarea eustriata arises from the area striata through division of the uniform layer IV into 2 laminae, separated by the stria of Gennari. This conception is contradictory to Brodmann's idea, that the unistriated area is a regressive metamorphosis from the tri-striated lamina. The regio eustriata (18) forms in mouse, rat and dormouse 26% of the regio occipitalis, in squirrel 38%. The increase of the area seems to be a characteristic of animals living in day-light. Also, in the squirrel the ganglion cells of lamina IV are more differentiated than in the other rodents. In the lower forms they are vesicular, round, and contain only scanty cytoplasm. in squirrel they are more polymorph, have well developed dendrites and show an increase in Nissl bodies. The specific density of ganglion cells is in mouse 1044 cells per 1/10 of 1 cu. mm., in rat 653, in dormouse 580, and in squirrel 500. These numbers support Nissl's theory (in contradiction to Brodmann's) that a more highly developed cortex contains fewer cells per unit of volume than a less developed form. The laminae I-IV are considered as a physiologic unit. Expressed in percentage of the total width of the cortex of the area striata they are 48% in mouse, 53% in rat, 54% in dormouse, and 61% in squirrel. The corresponding figures for laminae I-IV in the regio occipitalis are 32%, 40%, 41%, and 50%. All these figures demonstrate the high development of the receptive organ for visual impressions in the squirrel and indicate that a highly organized visual function is reflected in a highly developed visual cortex.—*A. Weil.*

2259. WOLHYNSKI, F. A. Die Herznerven des Kalbes. *Zeitschr. Ges. Anat. Abt. 1. Zeitschr. Anat. u. Entwicklungsgesch.* 86(5/6): 579-607. 7 fig. 1928.—The nerves supplying the heart of the calf are arranged in 6 wide-meshed plexuses, 2 anterior, right and left, 2 posterior, right and left, 1 anterior on the atria and 1 on the sinus Halleri. The plexuses in all hearts supply approximately the same areas and consist of a varying number of fibers derived from the 2 vagi and the 2 sympathetic trunks, the largest stems coming from the ganglia stellata. In the coronary sulcus the plexuses lie both above and beneath the vessels and form very fine plexuses around them; all the plexuses are beneath the epicardium and pass to the heart either along the vessels or in spaces between these and the heart surface, anastomoses between the plexuses taking place both before and after they reach the heart. A number of elongated ganglia occur on the atria in the neighborhood of the great vessels and ganglia are found also on the pulmonary veins and on the right and left superior venae cavae. The atrial septum receives fibers from the right posterior plexus and from the plexus of the sinus Halleri; the ventricular septum is supplied from the right anterior plexus.—*F. A. Wolhynski.*

2260. WOLHYNSKI, TH. Innervation des Herzkammer- und Vorhofsseptum des Kalbes. *Zeitschr. Ges. Anat. Abt. 1. Zeitschr. Anat. u. Entwicklungsgesch.* 86 (5/6): 608-638. 14 fig. 1928.—The nerve supply of the atrial and ventricular septa is derived from plexuses 1-4, using Worobiew's terminology. The atrial septum has 3 plexuses, 2 subendocardial, right and left, and 1 in the myocardium; these arise from stems 2, 3, 4 and 6 of the extracardial plexus. In the ventricular septum there are 5 plexuses, 2 subendocardial, right and left, and 3 in the myocardium; all of these are constant and definite in position. The atrial septum is richly supplied in

all its parts with ganglionic nodes, similar to those of the atrial walls; in the ventricles, nodes occur at the apices of the papillary muscles and in the His-Tawara bundle. This bundle is connected with the extracardial plexuses by stems belonging to the 2, 3, 4 and 6 plexuses, these stems joining the node, the crus commune and the limbs of the bundle. In all parts of the bundle there is a large number of strong nerve stems, ganglion cells and nodes, and its nerve stems anastomose with the neighboring stems of the plexuses of the septum.—*T. Wolhynski.*

2261. WISCHNEWSKY, A. S. Die Aufbautypen des Ramus descendens nervi hypoglossi. [The structural type of the descending branch of the hypoglossal nerve.] *Zeitschr. Ges. Anat. Abt. 1. Zeitschr. Anat. u. Entwicklungsgesch.* 92(3/4): 551-564. 8 fig. 1930.—Based on 70 human and 4 monkey specimens.

GENITO-URINARY SYSTEM

2262. BECHER, HELLMUT. Über Drüsen in kavernösen Räumen, endoepitheliale Drüsen und die Verbreitung des Zylinderepithels im weiblichen Genitalkanal von Tamandua tetradactyla L. (Myrmecophaga). *Jahrb. Morph. u. Mikrosk. Anat. Abt. 2, Zeitschr. Mikrosk.-Anat. Forsch.* 20(1/2): 253-286. 25 fig. 1930.—The uterus of *T. tetradactyla* is simple and pear-shaped. The extended ovaries lie free (not in an ovarian sac) and are attached to the dorsal side of the broad ligament. The short, plump oviducts are provided with an abundantly fimbriated slit-like abdominal opening. The uterus passes into the vagina without distinct macrosopic boundary, so that there is no clearly definable cervical segment, though such a region is to be recognized, on closer examination, by shallow mucosal folds (unlike the smooth mucosa of the body of the uterus), by glands in the mucosa, and by the tendency of the epithelium to form endo-epithelial cell-groups, as well as by its special behavior during pregnancy. In the vagina the mucosal folds are deeper; no such glands are present as in the cervical segment. The vagina unites in the urogenital sinus with the urethra, which lies close to the ventral wall of the vagina. The urogenital sinus extends as a canal 1.5-2 cm. long into the outer genitals, which consist of a short cone with a cleft-like opening. In the inner layers of the uterine muscularis dense networks of veins create, between the entwined muscle fibers, broad lacunae which justify the use of the term "corpus cavernosum uteri." Elastic fibers surround the venous hollow of the corpus cavernosum with a dense web penetrating the muscle bundles. During pregnancy and in pre-estrum the corpus cavernosum is especially pronounced. Since the corpus cavernosum extends into the deep portions of the tunica propria of the mucosa, the uterine glands come into close proximity with the blood-spaces. In many cases the bases of the glands float in the cavernous spaces and large sections of the circumference of the glands are immediately surrounded by blood-spaces. In the cervical segment of the uterus the epithelium tends to form endo-epithelial gland-cell groups which may be regarded as ontogenetic developmental forms of true ecto-epithelial glands. All stages of the transition from simple endo-epithelial gland-buds to endo-ecto-epithelial, many-chambered glandular cysts were observed. The entire length of the vagina down to its junction with the urogenital sinus has a simple columnar epithelium; the sinus, below its junction with the urethra and the vagina, has a many-layered squamous epithelium. In the animals examined a parasite, apparently *Filaria aequalis* Molin, was present in the urinary and genital organs.—*Author's summary (transl.).*

2263. BENAZZI, MARIO. Osservazioni sulla struttura dell'epitelio vaginale di "Mus musculus" in alcune condizioni biologiche. [Structure of the vaginal epithelium of Mus musculus in certain biologic conditions.] *Monitore Zool. Ital.* 41(6): 143-150. 2 pl. 1930.—The author studied the vaginal epithelium of *Mus* in oestrus, after parturition, during and after lactation, before puberty and in prolonged anoestrus in castrated ♀♀. In the first few days after parturition the vaginal epithelium showed the development of the oestral cycle, while in the following days and up to the termination of lactation there was a cessation of the sexual cycles; 20 days after labor and during lactation the vaginal epithelium consisted chiefly of 2 layers of cells. In an adult ♀ 35 days after castration the vaginal epithelium consisted of 2 layers of low, cubical cells while in another ♀ examined 55 days after castration the vaginal epithelium was composed of 4 or 5 layers of cells, the superficial layer showing cells in a state of mucoid degeneration, and the epithelium was infiltrated by leucocytes. This study shows the possible existence of a shortened vaginal cycle in castrated ♀♀ as pointed out by other authors.—*M. Benazzi (transl. by J. DeCarlo).*

2264. BENSLEY, R. R., and ROBERT D. BENSLEY. The structure of the renal corpuscle. *Anat. Rec.* 47(2): 147-175. 5 pl. 1930.—Study of the glomerulus by means of the silver-citrate method of R. D. B., by the kallitype method, and by various modified Bielchowsky methods for the impregnation of connective-tissue fibers shows that the glomerular membrane consists of 3 layers: the glomerular epithelium, consisting of a continuous layer of separate cells, not forming a syncytium, but covering the capillary loops without defect; a structureless basement membrane; a continuous endothelial lining composed of separate non-syncytial cells without defects. The capsule of Bowman is composed also of 3 layers: capsular epithelium, structureless basement membrane, reticular basement membrane. The connective tissue of the glomerulus is small in amount and consists of an investment of reticular (argyrophile) fibers around the entering vessels and thin and sparse fibrous extensions into the lobes of the glomerulus. The appearances which led v. Möllendorff to consider the glomerular epithelium to be a discontinuous investment of branched pericyte-like cells, are due to the presence in the more expanded epithelial cells of cytoplasmic thickenings. These thickenings are not cell processes with free spaces between, but are connected on all sides by thin continuous expansions of cytoplasm making a complete covering for the capillary loops.—*Authors (courtesy Wistar Bibl. Serv.).*

2265. CARLONI, E. Osservazioni intorno alle modificazioni gravidiche della mucosa cervicale, con particolare riguardo alla genesi della decidua. [Modifications of the cervical mucosa in pregnancy, especially as affecting the origin of the decidua.] *Rass. Ostetr. e Ginecol.* 39(6): 323-343; (7): 403-416. 13 pl. 1930.—On the basis of examinations of the cervical mucosae in 42 patients in various stages of pregnancy, Carloni rejects the theory that the decidua can be derived from the connective tissue, and confirms its derivation from epithelial tissues, proliferating intensely under the stimulus of pregnancy.—*From author's summary (transl.).*

2266. FALIN, L., und JUSSIN. Die Riesenzellen des Hodens. *Anat. Anz.* 70(11/12): 246-255. 6 fig. 1930.—The study is based on 55 prs. of testes from white rats which had been subjected to various procedures, as light treatment, thyroid feeding and mechanical and chemical testicular injuries. Testes of depancreatized cocks were also studied. Giant cells appear only in the canals of degenerating testes and are diagnostic of degeneration. All types of cells lining the tubuli contorti take part in their formation. They are most numerous at the height of degeneration and disappear if regeneration supervenes; they have no definite function. Exceptions to this are multinuclear structures arising from Sertoli cells, which are capable of active phagocytosis. Structures shown in a previous work are not called "giant cells" because this designation applies only to the present case. It would be more correct to call such cells "teratocytes" or pseudopolykaryocytes.—*H. W. Kaan.*

2267. GISBERTZ, H. Zur Morphologie der Glykogenablagerung im Vaginalepithel. *Monatsschr. Geburtsh. u. Gynäkol.* 84(1): 24-31. 1930.—The largest glycogen deposits occurred near the nucleus of epithelial cells. As a rule both the basal layer and the spaces between the epithelial cells were glycogen free, but occasionally glycogen deposits were found which probably had passed through the cell walls into the spaces. Where the epithelium was folded rich glycogen deposits occurred between the folds.

No relationship was found between changes in glycogen deposit and the menstrual cycle. At the climacteric, glycogen could no longer be demonstrated in the vaginal epithelium.

2268. **KÜSTERMANN, HANS. Systematische histologische Untersuchungen über die Venen des Uterus.** *Jahrb. Morph. u. Mikrosk. Anat. Abt. 2. Zeitschr. Mikrosk.-Anat. Forsch.* 20(3/4): 417-432. 3 fig. 1930.—All ages of nulliparae, and primiparae and multiparae from 16 to over 65 yrs., were represented in this study of about 170 uteri. While it was impossible to point out individual specific changes due to pregnancy, and while certain changes following pregnancy paralleled those of advancing age, still it appeared that the veins of uteri which had undergone pregnancy were characterized by a sum-total of factors, including increase in vascular spaces, formation of a thicker intimal pad, excessive production of elastic fibers and amorphous masses in the peripheral layers of the venous walls, and a characteristic degeneration of these structures in old age—a complex never seen in nulliparous uteri.

2269 **LOCKAN, ULRICH. Investigations in the epithelium of the uterus of domestic animals.** *Jahrb. Morph. u. Mikrosk. Anat. Abt. 2. Zeitschr. Mikrosk.-Anat. Forsch.* 14(1/2): 299-332. 1928.—In all, 188 uteri of cattle, sheep, horses, pigs and dogs were examined, with oviducts of 118. Ciliated epithelium was present in the oviduct save in diseased conditions or when corpora lutea were present. In the uterus the epithelium was generally nonciliated. The methods of preservation of the material are discussed.—*W. H. T. Baillie.*

Anz.* 69(18/19): 415-418. 1 fig. 1930.—Groups of seminiferous tubules found between the layers of the tunica albuginea in lambs' testes, represent a continuation of the tubules of the testis, which have pushed into the tunica. Though rather frequent in lambs (every 7th-8th testis) they were not seen in the testes of adults.—*M. Moskoff (transl. by R. R. Humphrey).*

2272. **STAFFORD, EDWARD STEPHEN. The origin of the blood of the "placental sign."** *Anat. Rec.* 47(1): 43-57. 3 pl. 1930.—The blood vessels of the rat's uterus undergo cyclical changes in arrangement and structure during pregnancy. From the 12th to the 15th days of gestation large blood spaces become intimately related to the endometrial glands and open into their lumina. From the glands blood escapes freely into the uterine lumen and appears eventually in the vagina, constituting the so-called "placental sign." The escape of blood is especially marked at the site of the decidua capsularis reflexa. On the 16th day and afterward there is a marked retrogression in the degree of endometrial vascularity. Similar cyclical changes in the vascularity of the endometrium are found in the gravid uteri of both guinea-pig and rabbit. However, open communications between vessels and endometrial glands have been found only in the rabbit. A placental sign is not described for either of these animals. In the dog and cat communications between uterine vessels and the confines of the border hematomata are seen.—*Author (courtesy Wistar Bibl. Serv.).*

Forsch.* 22(1/3): 80-89. 5 fig. 1930.—In addition to the earlier known cell types of the surface-epithelium of the oviduct [ciliated cells, cells of the glandular grooves and goblet cells] the author describes 2 additional types, viz.: the finely granular cells, the protoplasm of which is filled with acidophile granules of mitochondrial nature, and the secretory, ciliated cells. The best method to demonstrate all these cells simultaneously is by Kull's mitochondrial stain. The cell types are distributed as follows: infundibulum—ciliated cells, cells of the glandular grooves and goblet cells; albumen-region—ciliated and goblet cells; isthmus—ciliated, goblet and finely granular cells. In the caudal part are also some secretory ciliated cells. Uterus—secretory ciliated cells, goblet and finely granular cells; vagina—ciliated and goblet cells.—*J. Tehver.*

2275. **TINKLEPAUGH, O. L. Occurrence of vaginal plug in a chimpanzee.** *Anat. Rec.* 46(4): 329-332. 1 fig. 1930.—In making daily samples of the vaginal fluid of a mature ♀ chimpanzee, a gelatinous mass similar to the vaginal plug of rodents was repeatedly found during the receptive periods if the ♀ was caged with a mature ♂. It was not present when she was isolated from the ♂. The gelatinous material appeared in the form of granules within 24-36 hrs. after copulation began. In subsequent days of the receptive period it formed a finger-like plug, fairly dense at the cervical end and thinning out into a lining of the vagina as it extended toward the vulva. The mass was clear and practically structureless, except for the presence of sperm throughout and cavities at the cervical end which contained sperm in large numbers. Some of the specimens secured bore an outer layer of epithelial cells and leucocytes from the vaginal wall of the ♀.—*Author (courtesy Wistar. Bibl. Serv.).*

2278. **MÁTYÁS, J. Mikrometrische vergleichend-anatomische Studien an den Knochenröhrchen II, III, IV.** *Acta Litt. Sci. R. Univ. Hung. Francisco-Josephinae Sect. Sci Nat.* 2(2): 142-175. 1926; 2(3): 229-253. 1927; *Act. Litt. Sci. R. Univ. Hung. Francisco-Josephinae Sect. A. Acta Biol.* 1(1): 18-39. 1928.—Contains tables of osteological measurements used as a basis for a previous publication on variation appearing in the same journal. Explanatory notes with respect to their meaning are included. Three sets of tables are given. The first set attempts to determine how the transverse dimensions of a bone vary at the same point for animals of the same and of different species. The second set aims to discover how the transverse measurements of the different bones of the same animal vary. The third set deals with the variation in a single bone (femur) at different levels above and below the mathematical middle. The importance of the measurements is presented in the general part previously published. The following animals were included in the study: *Homo sapiens, Pythecus satyrus, Troglodytes niger, Felis leo, F. pardus, F. domestica, Lynx lynx, Canis lupus, C. familiaris, Equus caballus,* and *Aequus asinus.*

2279. **DEMETER, GYÖRGY, und JENÖ MÁTYÁS. Mikroskopisch vergleichend-anatomische Studien an Röhrenknochen mit besonderer Rücksicht auf die Unterscheidung menschlicher und tierischer Knochen.** *Zeitschr. Ges. Anat. Abt. 1. Zeitschr. Anat. u. Entwicklungsgesch.* 87(1/2): 45-99. 15 pl., 22 fig. 1928.—The material consisted of bones of frog, 5 reptiles (no. ser-

pents), 2 birds, 40 mammals, and man. Any 2 of the 41 mammals could be distinguished from each other by the cross sections of the middle of the femur. There is a specific "bone-structure pattern" and within individual orders of mammals there is a certain related "bone-structure pattern." Furthermore, certain orders present some common structural features. The following types were distinguished: The insectivoroid type with radial canals passing out from the marrow cavity and few Haversian systems (osteons). Some rodents and *Ornithorhynchus* have this type. Of the rodents, the Duplicidentata present a divergent type. Within the Carnivora the bone-structure presented 6 additional types, viz.:—*Putorius putorius*, cat, dog, bear, hyena, *Phoca vitulina*. A 9th type is found in the ungulates. Here the structural elements are arranged concentrically. The primates present a 10th type in which the developed bone shows no trace of type 9. This is a special type in which the perimedullary osteon type alone is seen in cross sections. These types may become important for the doctrine of evolution as well as for the classification of animals.—*H. F. Nachtrieb.*

2280. **EGGELING, H. von. Zur Morphologie des Beckenbodens.** *Jahrb. Morph. u. Mikrosk. Anat. Abt. 1. Gegenbaur's Morph. Jahrb.* 63(2): 243-259. 10 fig. 1929.—From observations on *Macropus rufus* ♂, *Eumetopias californianus* ♀, *Choloepus didactylus* ♀, *Tapirus americanus* ♀, *Pongo pygmaeus* ♂ and man ♂, the ilio-ischio-pubocaudalis muscle group may vary according to the shape of the ossa innominata, the extent and form of the pelvic cavity, the degree of development of the vertebral column of the tail and the attitude of the animal. The last appears to be the least directive. The conditions in *Macropus*, which usually stands erect and generally progresses on the hind legs, do not differ much from those in mammals which have well developed tails and walk on 4 legs. On the other hand, *Choloepus*, in spite of the upward bend of the pelvic exit and the absence of pressure of the viscera, possesses a firm muscular pelvic floor that is not fundamentally different from that of mammals with a strongly reduced tail and upright body position.—*H. F. Nachtrieb.*

2281. **JAFFE, HENRY L. The structure of bone, with particular reference to its fibrillar nature and the relation of function to internal architecture.** *Arch. Surg.* 19(1): 24-52. 18 fig. 1929.—Review.

2282. **MAIER, OTTO. Zur Frage der Entstehung der Gelenkform (an Hand eines Falles von pseudarthrotischem Kugelgelenke).** *Anat. Anz.* 70(13/17): 278-286. 5 fig. 1930.—A man of 36 suffered a fracture of the humerus through a war wound. The bone formed a remarkably regular ball-and-socket-shaped pseudarthrosis, which Maier regards as evidence that mechanical principles play the chief part in the forming of the joint bodies.

2283. **SIEGERT, F. Das Problem des Metacarpale I und Metatarsale I.** *Zeitschr. Ges. Anat. Abt. 1. Zeitschr. Anat. u. Entwicklungsgesch.* 92(2): 213-223. 8 fig. 1930.—Siegert finds that the metacarpal and metatarsal correspond normally and pathologically to the phalanges.

2284. **TANIGUCHI, TORATOSHI. Zur Kenntnis des M. sternalis bei den Japanern, nebst Bemerkungen über dessen häufigeres Vorkommen bei den Anenkephalen.** *Folia Anat. Joponica* 9(1): 1-8. 3 fig. 1930.—The author examined 261 cadavers of Japanese: 204 adults (183 ♂♂ and 21 ♀♀), 50 newborn, and 7 anencephalous fetuses (2 ♂♂ and 5 ♀♀). The m. sternalis occurred in 19 adult ♂♂ (10.4%) and in 3 adult ♀♀ (14%). It was present in 4 out of 50 newborn and in 3 ♀♀ (2 bilateral and 1 unilateral) out of 7 anencephalous monsters (10.8%, 8%, and 43%, respectively). The muscle was found 8 times on both sides, 11 times on the right, and 3 times on the left. The muscle is, therefore, present more frequently in ♀♀ and on the right side. It was found very often in individuals having psychosis (11 out of 22 adults). Comparing these results with those reported for other races, it was concluded that: The m. sternalis is found more frequently among Mongolians and negroes than among Europeans and Filipinos, and more often in Chinese than in Japanese. It apparently occurs more often in individuals having psychosis than in those suffering from other diseases. It is more common in anencephalous than in normal fetuses. There is no difference between Japanese and other races in regard to the frequency of this muscle in anencephalous fetuses.—*Author (courtesy Wistar Bibl. Serv.).*

2285. **TRETJAKOFF, D. Die endochondrale Knochenbildung und die Verkalkung des Knorpels beim Frosch.** *Zeitschr. Wiss. Biol. Abt. B. Zeitschr. Zellforsch. u. Mikrosk. Anat.* 9(1): 83-105. 12 fig. 1929.—The separation in time between calcification and ossification in the frog (*Rana esculenta* var. *ridibunda* Pall.) gives opportunity for detailed study of the cartilage cells and matrix during these processes. The proximal end of the femur was chiefly used but the results were compared with those in other bones. The transformations of the cells, particularly of their chondriome and reticular apparatus, are described and the remnants of these organellae are traced after the destruction of the cells. Calcification of the cartilage of both shaft and epiphysis plays a part in the mechanics of the bone and long precedes, and is independent of, the endochondral ossification which later involves both in a manner comparable to that in higher vertebrates. Consequently, calcification in the latter may also be a mechanical necessity and not merely a preparation for ossification. Endochondral ossification begins only with the entrance of perichondral buds; the cartilage cells, except a few in the epiphysis, degenerate and do not form osteoblasts. Calcification of the matrix appears first as spherules of Ca salts at a little distance from the cells. The process appears to have a certain independence of the life processes of the cells. Nevertheless, in areas in which the cells become calcified, and in these areas only, there is an hypertrophy of the chondriome which precedes the calcification of the cell. In these cases the chondriome next breaks up, the protoplasm transforms into cartilage matrix and calcification begins in it; usually peripherally, near the remains of the chondriome, but occasionally centrally around the degenerating nucleus.—*W. H. Piersol.*

2286. **WEEKS, CARNES. Occasional communications between the synovial sacs of knee and proximal tibiofibular joints.** *Amer. Jour. Surg.* 8(4): 798-800. 3 fig. 1930.—The synovial sacs of the knee and the proximal tibiofibular joints communicate in about 15% of cases. Where no such communication exists the close proximity of the 2 synovia necessitates injury to the popliteal bursa in exarticulation of the fibula. Acute suppurative arthritis of the knee joint may readily follow removal of the head of the fibula in the presence of infection.—*Author's summary.*

Entwicklungsgesch.* 92(3/4): 533-550. 8 fig. 1930.—Based on study of 100 röntgenograms from the gynecologic clinic, 413 röntgenograms from the surgical clinic, and 60 anatomical preparations.

2288. **ZAWISCH-OSSENITZ, CARLA. Die basophilen Inseln und andere basophilen Elemente im menschlichen Knochen. II. Besonderer Teil.** *Jahrb. Morph. u. Mikrosk. Anat. Abt. 2. Zeitschr. Mikrosk.-Anat. Forsch.* 18(3/4): 393-486. 72 fig. 1929.—The basophil islands and other basophil elements are the expression of the varying potency of the periosteum for the formation of pure cartilage or pure bone in (a) early stages of development and (b) in growth zones. They were studied from their origin to their disappearance, in a series of human femora from the 10th fetal week to the end of the first year. The basophil islands occur only in a definite kind of bone, island or mixed bone, which is found only at a definite stage of bone development. They are formed by a heaping up of degenerating periosteal or endosteal

cells, which become basophil. Especially in the deeper bone trabeculae they may be mistaken for remains of cartilage matrix or some other form of cartilage. Between the closely packed cells are also some which merely exerete basophil substance and become basophil encapsuled (pseudocartilage) cells. Later the islands, by the action of adjacent cells (osteocytes), become transformed into true bone substance (molecular transformation), by what may be regarded as a ferment action. Isolated degenerating cells that stain deeply with hematoxylin and are found in chondroid bone are also to be classed among the basophil elements. In finely fibred chondroid they have a strongly refracting capsule and form a transition to pseudocartilage cells, which occur also in coarsely fibred chondroid. Cement, addition and stoppage lines, which are defined, are also basophil elements. Most of these structures are formed from very flat degenerating cells with basophil reaction. —*From author's abstract (transl. by J. P. McMurrich).*

ALIMENTARY SYSTEM

2289. HUBER, JOSEPH. Der Faserverlauf des Periodontiums und seine Entwicklung in Milch- und im bleibenden Gebiss, dargestellt an einem unteren Schneidezahn der Katze. *Zeitschr. Ges. Anat. Abt. 1, Zeitschr. Anat. u. Entwicklungsgesch.* 90(1): 64-114. 35 fig. 1929.—The authors finds in the real peridontium only collagenous and no elastic fibrils. The dental sac of the temporary and permanent tooth consists of an almost vertical interlacing of meridional and equatorial fibrils. A stratification into strong outer and loose inner layers is already present in the enamel cap stage of the permanent tooth whereas it is seen only after the formation of the hard substances in the temporary tooth. Intersecting the basal fibrillation, radial fibers from the labial and lingual alveolar groove penetrate into the dental sac of the temporary tooth anlage, without, however, reaching the basal membrane of the enamel epithelium. The enamel organ of the permanent tooth is first imbedded in the fiber system of the periodontium of the milk tooth, and is later enclosed from almost all sides by bone lamellae of the linguo-alveolar wall. The basal fibrillation of the dental sac is preserved in this process. Only after the formation of the hard substances before tooth eruption do fan-like radial fibrils from the alveolar opening reach the tooth underneath the enamel border. At the eruption of the teeth, the dental sac is lost gingivally, equatorial fibrils remain in an intralveolar position around the neck of the tooth, meridionally they remain longer around the root. Equatorial fibers are lacking in the erupted tooth. There is a repeated interlacing of the radial fascicles, and a tangential insertion. In the tooth which is closing apically there are still to be found purely meridional fibers running in the same direction as the vessels. At the level of the openings of the alveolar processes interdental radial fascicles stretch from tooth to tooth. A "Ligamentum circulare" in the sense of circular, that is, equatorial stratification of the individual fibers is to be noticed in the young developmental stages of the enamel organ, as well as in the unerupted tooth. But then, the equatorial fibrillation disappears entirely after the eruption of the temporary, as well as of the permanent tooth. A separate nomenclature of the ring-shaped arrangement of radial and radial-meridional fascicles at the level of the openings of the alveolar processes as "Ligamentum circulare," therefore, seems unnecessary and misleading. Subapically, there are radial and radial-meridional fiber lines which are crossed by meridional ones. A double stratification of the peridontium as found in the dental sac is no longer found in the erupted mature tooth. The peridontium is uniformly fibrillated from the inner wall of the alveolar process to the tooth.—*J. Huber (transl.).*

2290. JORDAN, H. E. The pigment content of the liver cells of urodeles. *Anat. Rec.* 48(2): 351-365. 2 pl. 1931.—In *Amphiuma* approximately half of the hepatic parenchyma contains a voluminous content of finely granular brownish pigment. The pigmented cells in sections occur in groups of from 2 or 3 to many, corresponding with transverse or oblique sections of tubules. Appearances suggest a division of function between pigment-handling tubules and the usual type of hepatic tubule. Only a small number of the cells in any section, and in these only a variable number of larger granules, react to the ferrocyanide test for iron. Livers of *Triturus* vary greatly in their content of pigment. When only a small amount occurs, it is confined to macrophages within sinusoids; where much appears, it occurs also in Kupffer cells and certain hepatic cells. The spleen contains many macrophages with ingested erythrocyte fragments converted in part into hemosiderin granules and iron-free pigment granules. These cells pass into the liver sinusoids where, following disruption, they deposit their mixed content. This is phagocytosed by Kupffer cells and then transferred to liver cells. Here it occurs for the most part as minute spherical iron-free granules. Apparently identical granules occur in bile from the gall bladder.—*Author (courtesy Wistar Bibl. Serv.).*

2291. ROGOSINA, MARIE. Beiträge zur Kenntnis des Verdauungskanals der Fische. I. Über den Bau des Epithels im Pylorusabschnitt des Magens von Acipenser ruthenus L. *Jahrb. Morph. u. Mikrosk. Anat. 2. Abt. Zeitschr. Mikrosk.-Anat. Forsch.* 14(3/4): 333-372. 26 fig. 1928.—The epithelial cells of the pyloric region show a basal zone which is granular and a peripheral, or outer zone which is free from secretory granules, the protoplasmic zone. The process of secretion may be divided into 3 stages which are related to these zones. The presecretory granules are formed in the basal zone. These granules are associated with the Golgi apparatus, and their final solution takes place at the juncture of the basal and the protoplasmic zones. This process is similar to that described by Nemiloff for the epithelial cells of the epididymis. Among the epithelial cells in the pyloric region are cells which exhibit deeply staining acidophile granules. These are unicellular glands discharging their products directly into the lumen of the stomach. The staining reactions as well as their large size during the height of their activity indicate that they are related either to the Paneth cells or to the enterochromaffin cells.—*S. P. Miller.*

2292. WHILLIS, J. A note on the muscles of the palate and the superior constrictor. *Jour. Anat.* 65(1): 92-95. 3 fig. 1930.—There seems to be a constant band of muscle fibers passing from the superior constrictor into the palate, said fibers on a level with the ridge of Passavant. The author believes they play an important part in shutting off the naso-pharynx, and should be given the name of palato-pharyngeal sphincter.—*From author's summary.*

PHYSICAL ANTHROPOLOGY

2293. BLACK, DAVIDSON. The lower molar hominid tooth from the Chou Kou Tien Deposit. [In Chinese and English.] *Palaeontologia Sinica [Peking] Ser. D,* 7(1): (1-28). 2 pl., 8 fig. 1927.—Continued research work by the Geological Survey of China, at the Chou Kou Tien Deposit near Peking, has brought to light in recent years the well-known finds of human phyletic significance. The first lower left permanent molar of an immature individual represents the latest yield in the combined efforts of the Survey in cooperation with Peking Union Medical College (1927). From the morphological and metrical investigation comparatively carried on throughout, a combination of hominid and anthropoid characters was evinced which justified the identification of the find as pertaining to the basal Quaternary group of primary hominid forms such as the Trinil, Heidelberg, *Sinanthropus* (sp. *pekinensis* Black and Zdansky). The relationship between the previously recovered 2 teeth from the same site (1920; Zdansky, Bull. Geol. So. China, V(3-4): 279-283. 1927) appears also established. The author, relying on the Central Asiatic origin of primates and man, conceives of a subsequent dispersal of these forms in various directions including the east.—*B. Oetteking.*

2294. BOLK, L. Vergleichende Untersuchungen an

einem Fetus eines Gorillas und eines Schimpansen. *Zeitschr. Ges. Anat. Abt. 1, Zeitschr. Anat. u. Entwicklungsgesch.* 81(1/2): 1-89. 1927.—The vertex-anus length of ♀ chimpanzee fetus is 24 cm.; ♂ gorilla fetus, 23 cm.; when fully extended chimpanzee is 185 mm., gorilla, 170 mm. Gorilla was still in uterus, the position much like human, the chief difference being in the disposition of the extremities. Skin of gorilla is scarcely pigmented, much resembling Dutch fetus of same age. Pigmentation of chimpanzee was much farther advanced. This animal exhibited a Mongolian spot. Gorilla spine measured 152 mm., that of chimpanzee 162 mm., 6 mo. human fetus 160 mm. As gestation period of anthropomorphs is unknown, parallel developmental stages between human and anthropomorphs cannot be established, though these seemed similar. Young anthropoid apes show more resemblance to man than do adults. They resemble one another in relation of size of cerebral and facial parts of head and in skull contours. The outer ear is higher in the 2 apes and they are more markedly prognathous. Cephalic index of chimpanzee was 83, gorilla 89.9, human fetus 82.7, all brachycephalic. Thus, difference in position of head on neck cannot be attributed to skull type, nor to position of foramen magnum. The foramen magnum of very young anthropoid apes is only slightly farther back than in man. Cranial base index is about the same and the backward displacement of the foramen occurs in postnatal growth. Typical pithecoid position with the cervical spine oblique on longitudinal axis of head and stooping forward of body is indicated in the fetus. Meatus acusticus of the eye balls and orbits is lower in man in accordance with the skull base and points to greater intracranial height and greater brain size. It is more marked in gorilla than in chimpanzee. Front portion of cranial cavity is larger. The salient feature is the snout. Prognathism in most species is the consequence of bending upward of face. This does not occur in primates, where prognathism is produced by forward displacement of the nasal floor and elongation of the jaw. The large snout of gorilla remains subcerebral. The exophthalmus of the human embryo is not as pronounced as in anthropomorphs, though marked in the negro fetus. It is reversed, especially in gorilla, because of the enormous supraorbital ridges. The organs of sense grow rapidly and there may be a discrepancy between growth of orbit and eye-ball. In anthropomorphous apes and the white race, the sides of the orbits grow forward around the eye ball, leaving the Mongolian race behind them, in the fetal stage, in this respect. The facial formation definitely differs, the chimpanzee having numerous wrinkles, while the gorilla is smooth. Lifting of the root of the nose later causes folds and epicanthus to disappear. Where the root of the nose is not lifted the epicanthus persists, as in Japanese. Chimpanzee remains more fetal than gorilla in this respect. Chimpanzee hair is dark brown, curly, implanted in tufts as in negroes, while gorilla has straight, shorter hair. While most of the face is bald, upper and lower lips and chin are bearded in both fetuses. Hair is longer and closer in gorilla, that of body the same as in man for both. Man's skin continues in the fetal state. The author considers the development of man to be based on factors within his organism, not on the effect of his surroundings; upon biologic effects, evident in all primates, but most effective in man. All typically human qualities rest in one common cause, not only the physical, but to an extent the functional, though climate and nutrition have a modifying effect. The process is so slow that much larger mammals are senile at a time when man is not yet adult. The horse doubles its weight in 60 days, man in 180. Dentition is retarded because of the prominent chin. The gradual change can be due only to the function of the endocrine system. The body constitutes a compound of endocrines which may progress individually. The generative and the somatic systems, especially in the ♀, develop at varying pace and some are arrested at an incomplete stage. Retardation may amount to infantile, fetal fixation or to elimination of a morphologic characteristic. "Man's course of morphologic sequence constitutes a purely hormonal phenomenon." Disease or abnormalities of the endocrine organs in man may restore lost characteristics, for instance, hair, cutaneous pigment, etc. Fetalization is the clue for the closer resemblance between younger individuals of man and anthropomorphs. Characteristics commonly called human in the apes are fetal. The adult constitutes an incomplete phase of the primary type. "Man is a sexually adult primate fetus." The author brings racial differences under the head of fetalization, where single characteristics show various degrees of retardation. Denudation, often attributed to man only, already exists in anthropomorphous apes, where hair on head is present in the last fetal stages, while the trunk is still nude. This shows the error in considering loss of body hair as due to outer influences. In man the beard became subject to sex hormones and at last took on the significance of secondary sex feature. In general, the hair of the trunk in gorilla and chimpanzee is implanted cranio-caudally, except in the axillary and inguinal regions. The author does not consider the direction of motion of the body (cranio-caudal) as adequate explanation for the direction of the hair. For the cranio-caudal direction of the hair the oral opening must be considered as the cranial starting point of the currents. This opening was of use to the animal and should be considered as an adaptation. The direction of the hair follows the development of the extremities. Centers of divergence are secondary; they and divergence spirals are due to the same causes. Chimpanzee has large ears, while gorilla, orang and man have small ears. The breadth of the fetal ear of chimpanzee is greater than the length, whereas in the adult length is greater. The chimpanzee ear is more primitive than that of other anthropomorphous apes. The lobe is absent as in all anthropomorphs. The human ear, especially the free lobe, has fetal characteristics. The external sex organs of chimpanzee ♀ were large, those of the gorilla ♂ very small. Sparse light hair was found on the penis and adjacent portions of the scrotum, which had no pronounced sac. The ovaries showed much connective tissue. This points to the low sexual activity of organs of internal secretion in gorilla, which is known to copulate very infrequently. The chimpanzee fetus had large labia majora with slit-shaped vulva; the labia reach around the clitoris, the main portion of which is later exposed. In comparing proportions of the extremities and trunk, the author measured the long bones, to avoid misleading comparisons by inclusion of parts of the hands and feet. In the fairly young human fetus the leg is longer than the arm. At some time in human development this relation must have been reversed, for the anterior extremity is the first to propel itself. This primary relation has been preserved by the anthropomorphs. The longer legs are not specifically human, as they are encountered in other mammals. Difference in length of the extremities increases with growth. The forearm does not grow as intensely as the upper arm in the course of life; the leg, however, though shorter, grows more than the thigh. The proportions in gorilla are the reverse of the human. It must be observed, however, that during the second growth period radius and ulna become markedly bent. The anthropomorph forearm grows less than the upper arm, and the leg more than the thigh. In chimpanzee, it seems, upper arm and thigh grow as much as forearm and leg. In man the fetal arm constitutes 9/10, in the adult 7/10. In man the growth of the lower extremities is more intense, in the anthropomorphs that of the upper. Preponderance of the anterior extremities is an early embryonal feature. The adult anthropomorph shows approximately the same relation between thigh and leg. Both the erect position of man and the requirements for the passage of the large human head through the pelvic opening influence the difference of the lower portion of the pelvis, but the human does not diverge as much from embryonic conditions as do other primates. The bony pelvis seems specialized. It is less differentiated in an ontologic sense. Man's ancestors undoubtedly had

a pelvis like that of the primates, though ontogenic studies have not yielded proofs. The human pelvis has stopped at a younger developmental stage. It is fetal, just as in man's skull. Young simian fetuses, on the other hand, approximate the human. Erect posture alone did not produce the human pelvis. The external genitalia in the ♀ chimpanzee fetus and adult are moved toward the back; in man they are much more ventral. In anthropomorphs the body axis has been stretched in the course of development, as in other mammals, while in man the caudal portion has preserved the embryonal body axis. The more complete extension of the body axis in chimpanzee has resulted in the lower extremities being attached more caudally than in man, which becomes evident in studying the attachment of trochanter major. The anterior extremities are nearer the cranium.—*B. Bickel.*

К вопросу об оценке упитанности по методу Oeder'a. **[Development of subcutaneous tissue by the Oeder method.]** [French résumé.] Материалы по Антропологии Украины (*Anthrop. Ukraine*) 1: 68-71. 1926.—The authors examined 4023 Ukrainian soldiers from Kharkov, using Oeder's method for evaluation of development of subcutaneous tissue. The average thickness of the tissue was 9.5 mm.—a low figure explainable, no doubt, by the fact that the subjects had been working hard in the fields and were not well nourished. A group measured 2 mos. prior had a slightly greater development of subcutaneous tissue. The authors stress the value of the precision and simplicity of the Oeder method in measuring the subcutaneous tissues.—*From authors' summary.*

2298. **ERASMO, GEREMIA D.' Avanzi eneolitici della caverna del Cervaro presso Lagonegro. [Neolithic remains in the cavern of Cervaro near Lagonegro.]** *Atti Accad. Sci. Fisiche e Matema.* 17(1): 1-26. 6 pl. 1927.—The skeletal remains found during 1911-12 by De Lorenzo and Di Cicco in an heretofore unknown and unexplored cavern, between Saîerno and Potenza, were studied by the author. They are now in the Institute of Physical Geography of Naples and in the Provincial Museum of Potenza and include a calvarium, fragments of skulls, mandibles and isolated teeth, long bones, a few vertebrae and ribs and a few portions of carpal and tarsal bones, the whole belonging to at least 6 skeletons. The least damaged calvarium might fall, because of its horizontal index, into a variation of the Crô-Magnon type, although in its cephalic index (79) it falls between a brachycephalic and a dolichocephalic type. This renders less probable the hypothesis that it might belong to a Crô-Magnon type, especially since the bones are rather thin and the osseous-muscular prominences are not very marked. The mandible is rather thin, with a well-formed chin. If the calvarium seems to indicate a more recent type, the long bones exclude totally their belonging not only to the Crô-Magnon type, but also to the Neolithic type predominant in France. The principal characteristics of the long bones of the Crô-Magnon type—pilaster index of femur, platycnemia and well developed marking of the humerus—are completely absent. Only 1 fragment of a femur presents a sharp crest of moderate development, not at all, however, like a true pilastric index of femur. The talus and calcaneus existing in this material belong, without a doubt, to a fine type. The study of the bones shows that they represent a recent and advanced type of humanity, and this view is confirmed by the study of the stone objects and ceramics in the cavern.—*G. A. Bica and T. T. Job.*
